Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE

MECHANICS' MAGAZINE,

AND

JOURNAL OF ENGINEERING, AGRICULTURAL MACHINERY, MANUFACTURES, AND SHIPBUILDING.

VOL. IX.
(NEW SERIES.)
JANUARY TO JUNE, 1863.

105020-D.
NS, 9

LONDON:
ROBERTSON, BROOMAN, & CO., "MECHANICS' MAGAZINE" AND PATENT OFFICES,
166, FLEET STREET, E.C.

INDEX.

A

Abridgements of specifications, 380
Academy of Sciences, 31
Accidents in mines, the prevention of, 68
Action of heat and force upon matter, 231
Admiralty, lords of the, and boat lowering, 41
  ,, policy in naval construction, the, 89
Airy, G. B., F.R.S., hot-rolled and cold-rolled malleable iron, 122
Alkali manufacture nuisance, the Argus, 381
Alps of Savoy, on the forms of the stratified, 459
Aluminium bronze, 46
  ,, malleability of, 289
  ,, on, Lieut.-Col. Strange, 288
  ,, resistance to compression, 288
  ,, tensile strength of, 288
  ,, transverse strength of, 289
American cartridge, novel, 417
  ,, inventions, 195, 358
  ,, iron bridges, 343
  ,, iron-clads, 412
  ,, new method of loading rifles, 293
  ,, timber bridges, by J. R. Mosse, C.E., 162
  ,, umbrella stand, 293
Analysis of cast iron, 335
Analytic universal telegraphy, 91
Anchors and chain cables bill, the, 417, 440
  ,, testing chain cables and, 360
Anti-incrustation composition, 238
Appold's valve for regulating the discharge of water, 56
Architects, the education of naval, in England and France, 358
Armour and backing, 455
  ,, plates, the manufacture of, 457
  ,, ,, the value of wood-backing to, B. Cheverton, 347, 396
Armstrong, Sir William, 133
Artillery, improvements at Shoeburyness, 220
  ,, rifled, 1
Arts, Scottish Society of, 307, 329
  ,, Society of, 1:9, 202
Atlantic cable, by "Philo," 134, 239
  ,, telegragh, "An Old Sailor," 105, 292
Atmospheric trip hammers, 325
Austrian gun-cotton, 294
Axle bearings, 220
  ,, ,, Donkin's, 305

B

Balfour, J. M., reflectors for lighthouses, 40
Balloons, on scientific experiments in, 413
Barbor, G., on the build and equipment of passenger steam vessels, 58, 103, 117
Barnaby, N., on the steering of ships-of-war, 269
Bathoe, Chas., fog signals, 293
  ,, ,, tensile strength of iron and steel, 13, 44
Bearings or steps, improved, 236
Bees, 126
Bessemer process in France, 441
Belt, W. Clissold's driving, 233
Belting, machinery, 213, 268
Birmingham manufactories, notes of the, 388, 404
Boiler and furnaces, Eastwood's, 430
  ,, explosion of, 137
  ,, incrustation of, 137
  ,, tubes, Brooman's, 460
  ,, ,, wrought iron, 356
Boilers, construction of, 137
  ,, high pressure, 387
  ,, steam, cast steel, in Prussia, 299
  ,, ventilation of underground, 292
  ,, Williams' impsovement in steam, 286
Bolton's improvements in telegraphing, &c., 16
Books, mechanical defects of modern, J. A. Davies, 381
Boring machinery, Harvey's patent, 379
Bottle washing apparatus, Gilbya's, 138
Brereton, R. P., Cornwall railway, 265
Brick, Bell's patent, 197
  ,, machinery, Lindemann's, 412
Bridge, Blackfriars, foundation stone of the new, 349
British navy in 1677, the, 417
Bruce, Jas., cotton, to acclimatise, 143
  ,, ,, new fibre for stuffing beds, 283
  ,, ,, ,, substitute for food, 106
  ,, ,, rearing silk worms, 126
  ,, ,, remedy for poisoning by strychnine, 61
  ,, ,, water glass barometer, 45
Brunton, J., works of the Scinde railway, 306

C

Cable, Atlantic, 134, 239
  ,, oceanic, J. H. Selwyn, Capt. R.N., 313
  ,, submarine, the France and Algiers telegraph, 239
Californian gold, 112, 169
  ,, flax, 395
  ,, mining in 1862, 199
Callipers, how to use. 157
Calvert, T. G., and R. Johnson, on the action of sulphuric acid upon heat, 274
Campbell, D., sulphuret of iron for cement, 40
Campbell and Johnson, Admiralty contract, Chatham docks, 293
Candles, the manufacture of composite, at Clichy, 463
Carpenters' jointers, attachment to, 127
Carriageways and footpaths, 215
Casement fastener, Lea's improved, 257
Cast iron, the weakness of, 184
Ceramic manufacturers, new material for, 389
Chain cables and anchors, testing of, 360, 440
Charing-cross bridge, the, by H. Hayter, C.E., 325
Chemistry of steel, 429
Cheverton, B., elasticity in the backing of armour plates, 396
Cheverton, B., on Mr. Reed's ships, 184
"Chillicothe," sketch of the iron-clad, 294
Circular movements, transforming, 239
"Civilian" and Mr. Reed, "Observer," 221
  ,, Chalmers' target, 364
  ,, combustible iron clads, 182
  ,, iron walls and their armament, 82
  ,, the chief constructor of the navy, 162
Clark, G., on cellular iron backing to armour plates, 286
Clare *v.* the Queen, the petition of right, 105, 111
Clifton suspension-bridge, 465
Clocks, on gravity escapement for, J. F. Cole, 123
Clod crushers, B. and J. Harrison's, 268
Coal and peat, Williams' apparatus for the distillation of, 121
Coal-cutting machine, 289
Coke for iron smelting, purified, 461
  ,, purification of, by E. Kopp, 155
Colburn, Z., on the strength of iron, 174
Coles, Captain, iron-clad ships, 156
  ,, ,, iron tripod masts, 158
Colliery locomotives, 321
  ,, ventilation of the Hibernia, 269
Compound engines, 319
Condensers, Selby's surface, 99
Conversazione of the Society of Civil Engineers, 407
Cooper, F. E., "On Marine Surveying," 328
Correspondence, 13, 30, 44, 60, 81, 104, 122, 143, 162, 182, 203, 221, 238, 256, 276, 292, 312, 330, 346, 364, 381, 396, 417, 433, 464
Corrosion, boiler, 136
Cotton, Emery's machine for ginning, 309
  ,, printing, 79
Croll's treatment of ammoniacal liquors, gas works, 102
Cutting machines, wheel, 111
Culverhouse, T. patent laws, 81, 123, 184, 221, 293

D

Dana, J. W., on the relations of death to life in nature, 71
Davies, J. A., cause of apparently cold steam, 81
Dawson, on marine surveying, 328
Defective blow-out apparatus, 137
  ,, safety valves, 137
Delpech's patent pump, 28
Dent's auxiliary balance, 56
Distorted indicator diagrams, 299
Ditchburn, on the progress of steam navigation, 310
Diving-bell, application of the principle of the, 432
Docks and harbour board, the Mersey, 127
Dockyard expenditure, our, 102
Domes, steam, for locomotives, 441
Dovetailing machine, the Burley patent, 326
Drainage, Dundee, description of, by J. Fulton, 114, 229
  ,, middle level, 310
  ,, works of Newport, description of, by A. Williams, 115, 229
Drains, new arrangement for inspecting, 81
Drawing rollers, &c., for spinning machinery, by W. Weild, 359
Drill your centres, 166
Duncan, R., on an improved slip dock, 41
Duplicate engines and machines, 391
Dyer, on the progress of steam navigation, 310
  ,, reply to Dr. Rankine's paper, 341

E

Earth, the density and rigidity of, by J. A. Davies, 204
Earth's atmosphere, on radiation through the, 199
Easton and Amos' wood sawing machine, 445
Electricity, experiments in exploding field mines by, 231
Elevators, grain, 425
Engine improvements, marine, 283, 423
Engine pistons, portable, 371
  ,, room telegraphs, 41
Engineers afloat, 339
  ,, Civil and Mechanical, Society of, 328
  ,, government, afloat and ashore, 2, 70
  ,, Institution of Civil, 54, 92, 114, 160, 178, 197, 229, 251, 267, 271, 300, 310, 325, 343, 359, 375, 391, 407
  ,, Institution of, in Scotland, 8, 13, 161
  ,, ,, Mechanical, 93, 94, 119, 139, 369
  ,, London Association of Foremen, 117, 222, 345, 431
  ,, North of England Institution of Mining, 143, 289
  ,, Society of, 174
Engineering literature, 215, 229, 442
Engines, compound, 319
  ,, locomotive, in the Exhibition of 1862, by D. K. Clark, 359
  ,, locomotive, Faulding's improvement in, 446

Engines, Humphrys' marine, 219
,, road and traction, 150
,, steam boiler, 136
,, traction, 31, 237, 247
England, the soils of, 390, 410
Evaporating apparatus, Peek's, 430
Exhibition, the Ottoman national, 13

F

Fanshaw's improved mode of catching fish, 345
Faulding's improvements in locomotive engines, 446
Fenton, the late James, C.E., 328
Fernie, J., on duplicate machines and engines, 391
Filth and Fever, 127
Fire-engine manufactory, Shand and Mason's, 52
Fire-engines, steam, "Constant Reader," 83
,, trial of steam, 73
Fires, London, 306
Flax-scutching machines, 462
Fletcher, L. E., report on steam-boiler explosions, 26, 78, 136, 201, 393
Floating batteries, Hyde's patent, 362
Flood waters of the Upper Thames, by Rev. J. C. Clutterbuck, 197
Fog signals, Chas. Bathoe, 293
Fogs and fog signals, 253
Food, a new substance for, Jas. Bruce, 105
Forge, Onion's portable, 216
Fortifications, by Captain Lendy, F.G.S., F.L.S., 69
Fowler's steam-balance-plough, patent right of, 191
Fouling of Ships, the, 287
Fracture, steam boiler, 136
Friction, 456
Froude, W., form of a differential wave, 251
Funicular action, G. B., 123
Fulton, J., on the drainage of Dundee, 114, 229
Furnace, Bliss's improved, 173
Furnaces out of shape, 136

G

Gas apparatus, Brooman's carburetting, 394
,, ,, Keeling's, 73
,, meters, Browne and Armstrong's improvements in, 238
,, ,, Shedlock's, 378
,, photogenic, 103
,, regulator, H. Baker, 330
,, works in Germany, 416
Gauges, pressure, 137
,, ,, J. M., 183
,, water, 137, 319
Gauge, safety of the Davy lamp, 289
"Georgia," the launch of the, 240
Gisborne's electric compass, 377
Gladstone, C.E., on an instrument for measuring the strain of ship's cables, 251
Glaisher, Jas., F.R.S., experiments in balloons, 413
Gold, and California, 112, 169
,, quartz, 429
Gossip, 14, 31, 45, 61, 83, 105, 144, 164, 205, 222, 240, 258
Goucher's beater for thrashing machines, 14
Government engines afloat and ashore, 2, 70
Grain, King's apparatus for measuring, 179
,, elevators, 424
Grantham, J., on Mr. Reed's paper, 285
Gravity escapement for clocks, E. B. Denison, 124
Gray, Dr. James, plan for cleaning bottoms of iron vessels, 41
"Great Eastern," repairing the, 29, 44, 105
Grey, Sir George, and road locomotives, 461
Griffiths' improved propeller, 43
Grievance, a patent, A. Lever, 382
Gun experiments at Shoeburyness, 173
,, thimble, Cowan's, 288
Guns and projectiles, 21
,, ,, C. F. T. Y., 81
,, ,, "Cosmopolitan," 61
,, manufacture of great, 417
,, rifled and smooth-bored, 247
Gwynne and Co.'s pumping engines, 330

H

Hachman, G., LL.D., Exhibition at Hamburgh, 44
Halstead, Admiral, on Mr. Reed's ships, 217
Hammers, Joy's improvements in, 58, 59
Harbours and docks, 5
,, of refuge, 133
Harpoon ship-log and sounding machine, Walker's, 216
Harvey's boring machinery, 379
Haseltine, George, international assimilation patent law, 81
Hay, W. J., on the fouling of ships, 287
Hayter, H., the Charing-cross bridge, 325
Heat as a mode of motion, by J. Tyndall, F.R.S., 425
High pressure rollers, 387
,, speed steam-engines, 336
Hinge, Archer's patent, 288
Holman's pumps and valves, 76, 95
Holyhead new pier, 417
Hopkinson, working of the steam-engine explained, 265, 285
Hornsby and Son's root-pulpers, 26
,, turnip-cutter, 42
Horsham, Dorking, and Leatherhead railway, 329
Horological Institute, the British, 31
Howden and Thresh's safety lamp, 43
Hydraulic presses, 81
Hydrostatic presses, Samuelson's improvement in, 7
,, ,, Shanks and Kohn's, 428
Hydrotestometer, the, 341

I

Ice-making machine, patent, 390
"Ignoramus," tensile strength of iron and steel, 13, 83
Illumination, artificial, 157
Indicator construction, 372
,, diagrams, distorted, 299
Indicators and Boilers, Young, C. T. F., 314
Injector, an improved, 45
Institution of Civil Engineers, 54, 92, 114, 160, 179, 197, 229, 251, 267, 271, 300, 310, 325, 343, 359, 375
,, of Engineers in Scotland, 8, 13, 181
,, of Mechanical Engineers, 93, 94, 119, 139
,, of Naval Architects, 248, 269, 273, 287, 301, 341, 345
International Exhibition, 5
,, ,, buildings, the, 417
Inventors' Institute, the, 100, 116, 380
Inventors of machines for the manufacture of textile fabrics, 408
Inventors of machines, payments for the protection of, 335
Irrigation works in India, 445
Iron and wood, "One of the Lignums," 347
,, and steel, strength of, Chas. Bathoe, 83
,, bridge making in Worcester, 361
,, bridges, American, by Z. Colburn, 343
,, cased ships, on, by E. J. Reed, 249
,, cellular backing to armour plates, G. Clark's system, 376
,, clad, launch of a Russian, 377
,, ,, men-of-war, 31
,, ,, ships, by Capt. Coles, 156
,, ,, ,, ,, W. Fairbairn, 249
,, clads, 330
,, ,, condition of our, 153
,, coated ships and modern guns, by Scott Russell, 248
,, influence of the blast in the quality of, 405
,, ,, ,, frost on, 461
,, manufacture, qualitative retrogression of, 373
,, ,, quantitative progress of, 338
,, or wood, 195
,, ,, for the navy? "Civilian," 203, 205
,, plated ships, by Mr. Samuda, 249
,, plates, to prevent oxydation and fouling of, 15
,, railway bridges in India, apparatus for sinking piers, by J. F. Strong, 94
,, shears in the Southampton docks, new, 126
,, shipbuilding by contract, 211
,, ships, apparatus for preventing the fouling of, by Dr. J. Gray, 252
,, ships' bottoms, fouling of, 194
,, ,, fouling of, by Alex. Doull, C.E., 432
,, ,, Griffiths' method of sheathing, 340
,, ,, Mulley's metal sheathing for, 341
,, ,, sheathing for, Muntz's patent, 428
,, the relation between the safe load and the strength of, by Z. Colburn, C.E., 174
,, the strength of, H. H. K., 204
,, trade, prospects of the, 460
,, tripod masts, Captain Coles patent, 158
,, walls and their armament, "Civilian," 82, 256
"Ironsides," new, the effect of shot on the, 362
"Italia," trial trip of the, 458

J

Jenkins and Jumelle's improved engine governor, 273
Jeune's substitute for leather, 57
Joints or connections for pipes and tubes, Taylor's 431
Joule, Dr., and Mr. Seguin's letter, 78
Joy's improvements in forge hammers, 58
,, ,, steam ,, 59
,, ,, tappet ,, 59
Jurors' report, International Exhibition, 5

K

Kirkaldy, D., tensile strength of wrought iron and steel, 8

L

Laird Brothers' tug-vessel "Columbus," 43
Laird's bill for testing anchors and cables, 340
Lamport, C., on the construction of iron masts and spars, 304
Lamps for mines, safety, 51
Launch of a Russian iron-clad, 377
Lawn-mowing machine, Shanks', 446
Lead, on the action of sulphuric acid upon, by T. G. Calvert and R. Johnson, 275
Leather, Jeune's substitute for, 57
,, yellow spots on, 79, 277
Lendy, Capt., treatise on fortification, 69
Light Locomotives, 403
Lighthouses and electricity, 427
Literary piracy, alleged, Alex. Macmillan, 60
,, ,, ,, J. Todhunter, 60
Locke, Joseph, the life of, 23
Locomotive, a new, 398
Locomotives, colliery, 321
,, light, 403
,, oscillation of, 355
,, owned by English railways, 83
Log, superseded, the, 417
London fires, 40, 306
Sewage, 106
Lubricator for steam engines, Clements' self-acting, 254
Legal Intelligence—
Hyde *v.* Palmer, 116
Re Bastier, chain pump, 12
Smoke-consuming apparatus, 12
Worssam *v.* Godwin, 116

M

Machine belting, W. T. Rowlett, 293
Machinery belting, 213
M'Carthy's automatic safety valve, 378
McKay, Donald, the navy and the French empire, 73, 83
Mackrow, G. C., constructing iron bulkheads, 305
Magnesium, 442
Mail, sucking and blowing the, 38
Makinson, on internal disturbing forces of locomotive engines, 251
Mallett's folly, 361, 397
Manchester Association for Prevention of steam Boiler Explosions, 36, 78, 136, 201, 393
Manchester Literary and Philosophical Society, 78, 142, 144, 310, 341
Manufactures, notes on the Birmingham, 388, 404
Mare and Co., Millwall, 31
Marine engine improvements, 283, 423, 446
Masts and spars, on the construction of iron, by C. Lamport, 304
Metals, Weild's machine for cutting and shaping, 200
Middle level drainage, 310
Miller, D., structures in the sea, 267
"Minotaur," forgings for the, J. Ford, 60
Mine shafts, safety apparatus for guarding, 349
Mines, on safety lamps for, 51
,, the prevention of accidents in, 68
Mining lamp, a new safety, 275
Mirages, Dr. Joule on, 79
Miscellanea, 277, 293, 313, 330, 349, 366, 380, 398, 416, 433, 465
Molecular constitution of steel, 409
Moulding, Sagar and Rocliff's improvements in, 178
Museum of practical geology, 465

N

Napier, J. R., on least resistance for ships of limited breadth, &c., 311
Naval architecture, 339
,, ,, curious model of, 380
,, armour experiments at Shoeburyness, 323
,, construction and double propeller ships, J. Kennedy, 349
,, ,, the Admiralty policy of, 89
Navy of the French Empire, 73
,, chief constructor of the, 183
,, ,, ,, "Civilian," 162
,, D. McKay on the French, 55
Nile, the source of the, 398
Newnam's apparatus for crystallizing and evaporating, 308
Newton, on marine propulsion, 345
Notes on the Birmingham manufactories, 388

O

Oil of asphaltum for the preservation of boilers, 61
,, petroleum or American rock, 46
,, springs, 144, 240
Ordnance committee, report of the, on rifling small arms, 342
Oscillation of locomotives, 355

P

Palmer Brothers, iron shipping, 164
Palmers' projectiles, 462
Paper, new materials for, 235
Paper-pulp apparatus, Palser's, 393
Parliament House, Edinburgh, 127
Patent law, T. Moy, 123
,, on an international assimilation of, 37
,, reform, 3, 81, 123, 184, 221, 293
,, laws, Austrian and Prussian, E. A. Paget, 45
,, office, receipts and expenditure of, 101
,, right and political economists, 227
,, ,, legal procedure generally as regards, 102
,, rights, the duration of, 100
Patents, as to the cost of, 101
,, as to the granting of, 100
Persian Gulf cable, the, W. B. Passmore, 204
Petroleum for preserving wood, 435
Pneumatic despatch, inspection of the Postmaster-General, 38, 98
Photolectric engraving, 417
Photo-zincography, James H., Col., C.E., 105
,, ,, Staunton, H., 126
Pipe-joint, Robbins, Kean, and Case's, 409
Pistons, Ripley's improved, 429
Planing machines, Sellers', 218

Plates, manufacture of armour, 457
,, **steam boiler, blistered, 136**
Plough, Eddington's patent drain, 72
Political economy and patent right, 227
Preece, on railway telegraphs, 54, 179
Printers' blankets, material to be used in lieu of, 377
Projectiles and guns, 21
,, **successful experiments with, 154**
,, **velocity of, "Observator," 293**
Pulleys, improved differential, 392

PATENTS FOR INVENTIONS, 15, 32, 46, 61, 83, 106, 127, 144 165, 185, 205, 222, 241, 258, 278, 294, 314, 330, 349, 366, 382, 398, 417, 434, 460
  Abridged Specifications, 15, 32, 46, 61, 83, 106, 127, 144, 165, 185, 205, 222, 241, 258, 278, 294, 314, 330, 349, 366, 382, 398, 417, 434, 460
  Articles of Utility Registered, 36, 110, 422
  Inventions Protected for Six Months, 20, 50, 66, 88, 132, 168
  List of Designs for Articles of Utility Registered, 36, 110, 422
  List of Sealed Patents, 20, 36, 50, 66, 88, 110, 132, 148, 168, 190, 210, 226, 246, 262, 298, 318, 334, 354, 370, 386, 402, 421, 438, 470
  List of Specifications Published, 20, 36, 50, 66, 88, 110, 132, 148, 168, 190, 210, 226, 246, 262, 282, 298, 318, 334, 354, 270, 386, 402, 422, 438, 470
  Notices of Intention to Proceed with, 20, 36, 50, 66, 88, 132, 148, 168, 190, 201, 226, 282, 298, 318, 334, 354, 370, 386, 402, 421, 438, 470
  Patents Applied for with Complete Specifications, 225, 246, 262, 282, 318, 354, 370, 386, 402, 421, 438.
  Patents on which the Stamp Duty of £50 has been Paid, 20, 36, 50, 66, 88, 110, 132, 148, 168, 190, 210, 226, 246, 262, 282, 298, 318, 334, 354, 370, 386, 422, 438, 470
  Patents on which the Stamp Duty of £100 has been Paid, 20, 36, 50, 66, 88, 110, 148, 163, 190, 210, 226, 246, 262, 282, 298, 318, 334, 354, 370, 386, 422, 438, 470
  Provisional Protections, 19, 35, 49, 65, 87, 109, 131, 147, 167, 189, 209, 225, 241, 261, 281, 297, 317, 333, 353, 369, 385, 401, 421, 437, 469

THE

MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 2, 1863.

RIFLED ARTILLERY.

THE late trials at Shoeburyness have estalished beyond all cavil, that the whole of the expenditure, hitherto, upon Sir William Armstrong's inventions has failed to produce a naval gun superior for practical purposes to the old 68-pounder; and that his ingenuity, aided by an almost unlimited command over the public purse, has succumbed before the practical skill and private means of an individual manufacturer. The results of the experiments were so intelligible, particularly to tax-payers, that no show of scientific knowledge, no flourishing of mathematical formulæ, will be able to cloud the public vision. First, there is one fact which people will interpret in their own way, and which the War Office will find great difficulty to present under any other aspect. After the Russian war, the vote for warlike stores dropped down to £599,191, which we may therefore consider as its normal amount. Since then, that is to say in the last five years, and in addition to salaries and wages £8,141,277 have been voted, or upwards of five millions sterling beyond what would have been spent had the vote remained at the usual amount. What has caused this additional expenditure of five millions, if not the adoption of the Armstrong gun? If it be so, and it is the most natural conclusion, the nation's patience will be sorely tried to find that an outlay so enormous has been of no avail, so far as regards the armaments of our ships of war, and that, even in what concerns the land service, a better gun has been made by the most scientific mechanical engineer of the day, and that, not only without the assistance, but with the ill-favour of the Ordnance authorities. In presence of the crushing superiority of the Whitworth gun, it becomes a question of national importance what course the executive may determine to adopt. To continue now to manufacture Armstrong guns will be about as prudent as to fall back on carronades, or on cross-bolts; for in case of war, and of an enemy's iron-cased frigate, armed with Whitworth's, falling foul of the "Warrior" or the "Black Prince," the latter would have her sides smashed in and her between decks shelled out at a range at which Armstrong's bolts would be as harmless as paper pellets. This was conclusively proved by the late experiments, and it is mortifying in the extreme, after all the official boasting and extravagance that have occurred. Indeed, the history of the introduction of rifled ordnance into the service is not creditable to the enterprise of the authorities.

It is sixteen years since Major Cavalli, of the Sardinian service, and Baron Wahrendorff, of the Swedish service, brought out the rifled breach loading cannon. Four years later these two guns were tried at Shoeburyness, when the practicability and correctness of the principle were shown, although at that early stage there was abundant room for improvement. From the first the Swedish gun was the most successful; its bore was 6·37 in., and therefore nearly resembled our 32-pounder that weighs 56 cwt., and the bore of which is 6·375. The Wahrendorff gun threw a cylindro conoidal shot weighing 64 lbs.; and attained a range of nearly 4,000 yards. With a charge of 10 lbs. it exceeded the range of the 32-pounder by 1,100 yards. At a date anterior to that of the Shoeburyness trials Continental artillerists had satisfied themselves of the value of the Swedish invention, and they did not hesitate to recommend its adoption into the armament of men-of-war. M. Daru, in his report on naval artillery, May 1851, stated—"We think that in the very rare cases—where it will be compulsory to fire at long range at a distant ship, it will be necessary and sufficient to place on the forecastle and quarter deck a few rifled cannon, 30-pounders recently tried in Sweden, and which will complete the armament of men-of-war successfully, and in a manner truly formidable by the accuracy of their aim." Vice-Admiral Laine urged on the French Government the necessity of testing the Wahrendorff gun, and of introducing it into the navy. The armament which he proposed at the Enquête Parliamentaire for a French three-decker was—main deck, twenty-eight 30-pounders and four 8¾ inch shell guns; middle deck, thirty 30-pounders and four 8¾ inch shell guns; lower deck thirty-four 30-pounders; forecastle and quarter deck, twelve 30-pound carronades and four rifled Swedish guns. Nevertheless, both here and in France the question was suffered to fall into abeyance, though Lancaster about this time patented his system of rifling ordnance.

The Russian war made more than ever apparent the desirability of obtaining long range and accuracy of aim. Inkermann proved the rifle musket to be the queen of weapons, for to its efficiency our troops owed, in great measure, their escape from destruction, and the Russians their repulse. The huge expenditure of ammunition, and the little effect produced thereby, again directed attention to rifled ordnance. Lancaster supplied cannon, and, whatever might have been their practice, they failed to remove the prejudice in favour of smooth bores. About this time, also, Lord Paget exhibited a rifled gun at Woolwich, which stripped the lead coating from the shot as it issued forth from the muzzle, and scattered the fragments all round. It was as dangerous to friend as to foe. With the return of peace the question was again shelved, and the authorities appeared to concur in Sir Howard Douglas's opinion that "such guns (rifled ones) cannot enter into the armaments of ships of war, but they may be used with advantage for flanking defences in casemates, or in coast batteries for firing at objects at a great distance."

Meanwhile, the Woolwich authorities were slumbering, the Emperor of the French had remitted the question to the Committee of Artillery for investigation. A hundred and twenty years ago, Robins, the Quaker artillerist, stated that the imparting of spiral motion to shot would produce a complete change in the practice of war. And of that change the Emperor determined to take the first advantage. It has been shown above that the members of the naval commission were strongly in favour of the introduction of rifled ordnance, at a time when Earl Russell, the premier, and Sir F. T. Baring, at the Admiralty, had never given the subject a thought; and nothing, perhaps, is better calculated to show the strength of mind of Napoleon, his command over himself, and how, with the occasion, he can rise far above personal consideration, than this resolve of his. For he had then just completed the introduction of a field-piece of his inventiou—the Napoleon gun, as it was called—into the army. It was a 12-pounder howitzer gun, or an 8-pounder bored up to that calibre, mounted on an 8-pounder carriage, and capable of firing shell, shot, case, and spherical case, which were the only projectiles provided. The gun had been especially devised to carry out the new system of artillery which the Emperor had suggested while President, and which consisted in establishing field batteries of a uniform calibre, in place of batteries of 8-pounder and 12-pounder guns, and the howitzers of two different calibres. He had for years experimented with the gun, and had written in favour of it. When placed in position to carry out his theory, he had nearly 2,000 field-pieces re-cast, with which the army was supplied, so that *amour propre*, and even the policy of not allowing it to appear, he had made a mistake, or had wasted the national resources, would, had he been an ordinary individual, have operated to prevent his allowing a new system of artillery to be introduced under his very nose, and to the complete superseding of his own pet system. Yet, notwithstanding all this, the artillery factory in the Place St. Thomas d'Aquin, at Paris, was set to work to rifle all the mountain batteries consisting of 4-pounders and the old 8-pounders, while new guns were being cast to be rifled. The rifled Napoleon guns were intended to be used for sieges, and the rifled 4-pounders for field batteries. The extreme range was 3,000 metres, and the effective range 1,800. They were rifled with three grooves; those now in use are rifled on the Whitworth system, with the addition of the angles being cut off. What was the result of this innovation the reader does not require to be told. Magenta and Solferino amply recompensed the Emperor for any sacrifice of self-pride he may have made.

The history of the introduction of rifled guns into the French navy is equally instructive. French naval artillerists have for a long time been in favour of as close an approach to uniformity of calibre as possible, and, strangely enough, of the retention of carronades so many years after their expulsion from our service, on the demonstration of their inefficiency during the second American war. They evinced considerable hesitation to follow us in increasing the calibre and weight of ship's guns. In 1812 Napoleon decreed that the armament of a first-rate was to consist of 118 guns, weighing 378 tons. There were four calibres—32 36-pounders, 34 24-pounders, 34 18-pounders, and 18 8-pounders. In 1829 the first step was taken, to approximate to uniformity of calibre, by the issue of a royal *ordonnance*, which fixed the number of a first-rate at 120 guns, weighing 325 tons. They consisted of 66 30-pounders of the first and second class, 50 30-pounder carronades, and 4 18-pounders. In 1837 the shell gun of Paixhans, which had been proved twelve years previously at Brest, was introduced on board men-of-war. A first-rate carried 62 30-pounders, 4 8¾-in. shell guns, 38 6-in. shell guns—making a total of 120 guns, weighing 349 tons. The Government of the Republic, in 1848, simplified the calibre of the armament by fixing it at 16 8¾-in. shell guns and 100 30-pounder guns and howitzers, weighing 345 tons. The year following was marked by important changes. The carronade and 6-in. shell gun were expelled the service, and two new pieces introduced, the 50-pounder and the 30-pounder belonging to a new class (the fourth). The number of guns was fixed at 112, weighing 380 tons, viz., 6 50-pounders, 94 30-pounders, and 6 8¾-in. shell guns. Thus, during twenty years, the number of guns had diminished from 120 to 112, and their weight increased from 325 to 380 tons. The aim of naval artillerists on the other side of the Channel has been to obtain uniformity of [illegible] and guns easily worked, [illegible] range and heavy shot. The 50-pounder was intended to reply to our 68-pounder, as it throws a shot of 55 lb., and has about the same range, but it has not been looked on with favour, nor by any means as a step in advance. The favourite gun was the 30-pounder, because it was capable of firing solid shot or shell, and the latter projectile, with a charge of 8 lb., will penetrate 12 inches of oak at a distance of 1,400 yards. The 30-pounder, with an elevation that is easily obtainable on board a ship, could be relied on to hit an object at 2,200 yards. It required 14 men, and could be fired five times, while the 50-pounder took 16 men, and could only be fired four times in the same period. It is, therefore, not surprising that, when rifled ordnance was to be introduced, the rifling should be applied to the favourite naval gun—the 30-pounder. Accordingly, prior and during the Austrian war, the pieces of this calibre in stock were rifled. They were bored with three shallow broad grooves, having by no means a sharp twist—not much more than a quarter of a turn from muzzle to breech. The shell fired from this gun weighs 57 lb., and ranges 8,000 yards, and it is made after the invention of Mr. Lovell, published in 1844, with three feathers on the circumference, which are faced with zinc where they come against the edges of the rifle grooves. It is this gun—which, at the short range of 130 ft., is effective against French armour plates 12 centimetres thick—that has given rise to the tale about the 90-pounder adopted into the Imperial navy, which appeared in a letter to the editor of the *Times*, and was repeated at Cambridge by Mr. Aston. With respect to the gun which the *Times*' correspondent stated pierced a 4½ in. iron plate at 1,093 yards, so far back as August last year, we confess to be doubtful, for we have heard of at least a dozen inventions which have done as much before trial in the polygon at Vincennes, and after were never heard of. What tends to confirm the doubt is, that, at that very period, the armament of the "Solferino" was fixed at 52 rifled 30-pounders. At the same time we are perfectly aware of two things. The first is, that French artillerists, after ample trials, have come to the conclusion that the Armstrong gun is a mistake. They do not hesitate to speak of it with ridicule as a weapon of war. The second fact is, that Whitworth's system is perfectly well known to the authorities in Paris, and approved of by them; and that they possess mines, especially in the newly annexed districts of Savoy, which affords the best material for the production of homogeneous metal.

Under all the circumstances of the case—the complete failure of the Armstrong gun in penetrating power, as compared with the Whitworth gun—it is no more than what is due to a proper administration of national revenue, and to national security, to suspend rifling guns on the Armstrong system, until the authorities can do what the public did long ago—decide which is the best weapon.

GOVERNMENT ENGINEERS AFLOAT AND ASHORE.

SOME few weeks ago, we took occasion to comment, with some severity, upon the moral disabilities under which engineers in the British navy labour; and we have since had the satisfaction of learning that our remarks were not without effect upon the Board of Admiralty. That eventually those disabilities will be swept away, and a proper amount of respect be accorded by their brother officers to naval engineers, we firmly believe. With those moral grievances, however, the notorious physical disadvantages, which the same valuable class of men have at present to submit to, must disappear, if the service is to be recruited with efficient hands, and maintained with due dignity. The mess-berths of engineer officers of the navy, for example, are, in nine cases out of ten, unfit for human habitation, and the complaints which emanates from those who are so unfortunate as to occupy them are, very justly, both numerous and loud. How can the Admiralty, therefore, who are supposed to be, and who should be, using every effort to obtain competent engineers for the navy, hope to succeed in the task? Clearly, if the existing state of things be continued, they will not succeed; and the post of engineer in the navy, instead of being an object of ambition to educated and talented young men in our factories, will be regarded by them as a mere refuge for the destitute, and to be accordingly shunned. We have hope that so deplorable a consummation will be avoided, and that the worst days of the naval engineer are past.

Whilst advocating the cause of engineers afloat, let us not forget the claims of engineers ashore. In the Government steam factories of this country, there is, as is well known, a numerous body of skilful and highly intelligent engineers. These, too, are, in many instances, exceedingly dissatisfied with the working of the Admiralty rules and regulations which control their movements. As a proof that this dissatisfaction arises from no imaginary causes, it is our purpose to refer to circumstances which have transpired during the past year, in reference to promotions in the Royal Steam Factory, at Woolwich Dockyard.

In April last, a circular memorandum emanated from the Admiralty, and reached the various dockyards of the United Kingdom. It ran thus:—

"As one or more vacancies will probably shortly occur in the junior grade of officers in the dockyards, my Lords deem it desirable that these vacancies should be filled by persons of such age and acquirements that they may be expected, after some years' experience, to become well qualified to serve in the higher grades. This cannot be hoped for if persons of advanced age or low qualifications be selected. With this important object in view, my Lords consider that a somewhat similar course should be adopted in making the selection as obtains in respect of the shipwright officers, and of many others in the civil service, namely, by competitive examination.

"It may be expected that comparatively young men, thus selected, would be stimulated by a prospect of promotion to perform the duties first assigned to them, and to qualify themselves, as far as they may be able, subsequently to perform duties of greater importance.

"You are, therefore, to call on the captains of the Steam Reserves, and the officers of the factories, to report the names of such candidates, under their orders, as they may consider qualified to fill the situation of assistant-inspector of machinery at the factories.

"It being intended to subject the candidates to an examination at the Royal Naval College, at Portsmouth, to ascertain the extent of their mathematical acquirements, this qualification need not weigh with the officers in making their selection. They should take into consideration the mechanical abilities of the candidates, their experience and knowledge of steam machinery, and other practical qualifications, as well as their character, conduct, and general fitness for the office in question, as far as may be known to the officers, from personal knowledge, or can be ascertained from unquestionable testimonials.

"Together with the list of names, the age of each candidate, which must be between 25 and 35 years, where he was brought up, when, and how he was subsequently employed, should be stated; copies also of such testimonials as the officers consider important are to be forwarded, with any remarks on the several candidates which, in the opinion of the officers, ought to be known to their lordships before they make the ultimate selections for appointments.

"By command of their Lordships,
(Signed) "W. G. ROMAINE."

We have thought it desirable to reproduce this document *in extenso*, because it will materially assist the reader in comprehending fully the bearings of the question to which we draw attention. Nothing can be said against competitive examinations, provided they are fairly carried out; and the standard applied to candidates is in accordance with the nature of the duties they are desirous of fulfilling. To bring forward a high educational test in the promotion of officers from one grade to another, and especially among professional men in our dockyards, is, however, a questionable proceeding, and one open to very grave objections. It is evident that its result would be to make mere scholastic and theoretical knowledge take precedence of solid practical experience, which is the qualification most needed.

Their Lordships say, that they are desirous that the appointments referred to should be held by persons of such an age as that they may be expected, after some years' experience, to become well qualified to serve in the higher grades; and that this cannot be hoped for if persons of advanced age, or low qualifications, be selected.

What their Lordships mean by advanced ages is explained in the last paragraph of their circular, namely, beyond 35 years. They thus actually promulgate the absurd dictum that an officer who has served in an inferior position, no matter with what credit and honour, and who has attained the ripe age of 35 years, is unfitted for further advancement! He must then, according to the ruling of "my Lords," stand aside, and allow younger men to pass up the ladder of promotion. It is needless to discuss the mischievous and unjust tendency of such a doctrine. It is so palpably a wrong to faithful servants of the State, that no course of sophistry, as we think, could make it appear to be tinctured with fairness.

In the second paragraph of the circular quoted, the same authorities state that a similar course ought to be adopted to that already in force, with respect to the promotion of shipwright officers, namely, by competitive examination. Had their lordships really framed the regulations, touching engineer officers, on the model of those which govern the shipwrights' department, no reasonable ground for complaint would have existed, but they have done nothing of the kind. Like the Athenians of old, they "understand what is good," but do not practice it.

In the shipwrights' department, it is not only asserted, but made compulsory, that in order to rise to the superior positions of assistant master shipwright, and master shipwright, the candidate must have have filled the subordinate offices of artizan, leading-man, foreman, and inspector, and have held each for a term of three years. Inferior officers are also eligible for promotion until 50 years of age. Where, then, is the comparison between the two branches of the Government service?

In the shipwrights' department, too, the examination required at each successive step of promotion is clearly set forth, and, we believe, in most cases, faithfully adhered to; so that the officers engaged therein have every facility given them for earning advancement. The monstrous injustice of limiting the age of aspirants to 35 years in the one case, and extending it to 50 in the other, cannot but strike every ingenuous observer of the fact. Why, as a rule, engineers, at 35, have much of their business to learn, and are reckoned, out of the Government dockyards, young men.

In considering the enactments and assertions of the April circular, the idea has thrust itself upon us that "my Lords" were influenced in its concoction by the Report of the Committee of 1858-9, on Dockyard Economy.

That committee recommended that, in future, the superior officers of the shipwrights' department be taken, one-third from the rank of foremen, and the other two-thirds from some far off or exalted class. At page 40, and paragraph 359, of their report, the committee in question say, "For the superior officers not made from the rank of foremen, young men of superior standing and education, specially noticed by competitive examination" should be selected, and that "the young men thus entered should then be specially trained for the positions of assistant master shipwright, and assistant surveyors, and for those positions only, in the same manner as young commissioned officers for the army and navy are trained for their positions." The committee further proceed to state as their reason for this absurd dogma, that "It is not good to take young men of a lower position in society, such as sons of working men, and by an examination in which they have been put into competition with none but their own compeers, raise them at once into a position superior to that of their own fathers or families."

The monstrous doctrines thus coolly propounded met a severe rebuke from the late Mr. Abethell, master shipwright, of Portsmouth Dockyard, and assuredly cannot be too warmly denounced by all right-thinking men. It does seem, nevertheless, that the Admiralty is acting upon them in its treatment of Government engineers; for, at a competitive examination which took place lately at the Naval College at Portsmouth, for the purpose of filling the office of assistant to the chief engineer at Woolwich Dockyard, "theory" drove "practice" completely out of the field, and obtained the appointment. The candidates were twelve in number, and comprised the following:—One chief and four junior engineers in the royal navy; four leading men in the steam factories; and three draughtsmen. The questions put to the candidates were, to the extent of three-fourths, purely theoretical. Five hundred marks were considered the maximum of excellence, and at the close of the examination Mr. James Bamister, draughtsman, was found to have obtained 450, and the chief engineer of the navy 45.

After a brief interval, the appointment was conferred on the gentleman who obtained the greatest number of marks. He is now, therefore, an officer at Woolwich.

The successful candidate is known to possess very superior scholastic acquirements, and to be of studious habits. He has, in fact, all the accomplishments fitting him for the post of tutor in an academy, but none for that of assistant engineer of a dockyard. We believe we are right in stating that he never lifted a tool on a steam engine or in the construction of engine gearing, and that he was never present at the trial of a single steam vessel prior to his appointment at Woolwich.

We do not wish to disparage the gentleman who has thus been thrust, by the mischievous working of a board regulation, into a position for which he, of all others, must feel most painfully his unfitness.

To exalt thus ludicrously a gentleman distinguished only for scholastic acquirements, and for being under 35 years of age, at the expense of others who have *proved* their aptitude and acquirements in the great practical school of engineering, and who were thoroughly competent for the post he occupies, is a severe commentary upon the common sense of my Lords. It is this kind of treatment which drives the best men from Government service; and, consequent upon similar anomalies, at least five leading men of the Government Steam Factories have, during the last three years, left the British service altogether, and gone into that of Russia; three or four others have become superintendents of private engineering firms; and it will not be surprising if others follow their examples.

PATENT LAW REFORM.

So much has lately been said on Patent Rights, considered in the abstract, that we will not at present enlarge on this theme. When such names as Adam Smith, John Stuart Mill, Jeremy Bentham, Lord Brougham, Lord Stanley, M'Culloch, and Babbage can be cited in defence of any principle of Political Economy, it would be mere tautology to try our "'prentice hand" in adducing additional evidence. We have selected these names, amongst many others, as it is well known that none of these distinguished men were ever patentees, so that their testimony to the truth must be disinterested. We might also cite Sir David Brewster, Professor Wheatstone, and Baron Liebig, as being in favour of patents. They are, however, themselves patentees, so that we could not give their opinions as uninfluenced by personal considerations.

We believe that monopoly patents were first granted by our Tudor princes, in order to encourage foreign artizans to settle down in England, and thus fill up the devastation caused by the civil wars of the Roses. These monopolies were in opposition to the trade monopolies of the ancient guilds or trade corporations. The royal patents enabled the foreign artizans to exercise their several trades without being obliged to be members of the English guilds. Patents, intended to encourage trade, at last degenerated into the oppressive monopolies that were repealed by James I. The statesmen of that time, while correcting an abuse, saw that the system of patents was a powerful means for encouraging progress and invention. Our patent laws have given an example that has been followed by the Legislatures of all civilized nations.

The history of the steam-engine, of the cotton and iron manufactures, is the history of a succession of patents. The power of England may be said to rely on the genius of invention, fostered for nearly three centuries by the patent laws.

In those halcyon days of some eleven years ago, when the *Times* was better managed than it is now, that paper took a different view of patent right. Before it ignorantly let itself be transmogrified into an Armstrong gun, the the thunders of Printing-house Square were in a very different key. Armstrong guns have an ugly trick of bursting and recoiling on those behind them.

The following is an extract from a leader on Patent Law in the *Times* of 1851. After some remarks in favour of Patent Right, it says:—

"Such being the case as respects the justice, the policy, of this privilege, what, let us next inquire, are those peculiar and formidable difficulties, which are supposed to stand in the way of the legislator, when endeavouring to confer it as a reward upon a meritorious discoverer? We are told that, do what we will, there will be frauds practised on society by pretended discoverers, and upon real discoverers by unscrupulous pirates, and frauds to such an extent as to annihilate all possible advantage from the intended privilege. But, surely as regards pretended discoveries, the ordinary competition of men engaged in business may be safely relied on as an adequate security. If the asserted invention be useless, then is the community not injured in any way by granting a privilege with respect to it. The only loser in this case would be the person who had paid his fee for the evidence of his right—in other words, for his patent. If the supposed invention were merely pretended, and not original, then, as by experience we know, the pretended privilege would be treated as a nullity. This, undoubtedly, under any system, no matter how judiciously framed, would give occasion to litigation. But the possibility of litigation is a necessary incident upon the existence of law; and, if such danger of possible litigation be a sufficient reason for having no patent law, it is a sufficient reason, also, for having no law at all. The law that created rights, would be useless, unless it also gave the means of defending them when attacked; the means are to be found in litigation. The object of the legislator with regard to litigation ought to be, to make it dangerous only to the dishonest, and in the case before us, as in all others, that would be best accomplished by making the law itself unambiguous, and the remedy simple and cheap. The crying evil, however, of our existing system is that it entails upon the unfortunate person, who seeks for the protection of a patent, enormous trouble, vexatious delay, and wanton expense; and if in the discussions upon the details of the proposed measure, attention had been steadily directed to making the acquisition of a patent a matter of little trouble, and small expense, the time of the Legislature would have been more beneficially employed than in wrangling about principles, upon which most men of sense are agreed, or in bandying about imputations of unworthy motives, leading alike to a loss of temper and reputation.

"The obtaining a patent ought to be a matter o course; a small fee ought to be required, together with a specification of the invention; neither the value of a discovery, nor the question of originality ought, in any case, to be mooted upon the taking out of the patent. The real safeguard is not to be found in the vexation of preliminary inquiry, but in the interests of the public. They who are excluded from the enjoyment of the alleged discovery will be sufficiently on the alert to protect themselves, and thereby to shield the public from injustice. The pretended discovery will be invaded, and the useless one neglected. In addition to the fee exacted upon taking out a patent, an annual rent might be fairly required during the continuance of the privilege. By thus spreading the whole sum paid by the patent over the period for which it is in force, the tax levied upon the discoverer, in return for the protection and exclusive enjoyment given by society, would be in proportion to the value of this privilege. Those patents that were not successful would not be continued, while those that were profitable would be annually renewed. If the original fee were small, this rent would be cheerfully paid, and a law thus simple and just would further alike the interests of the public and the inventor."

Most of the above remarks of the *Times* are as pertinent in 1863 as in 1851. This is especially the case with the paragraph alluding to the discussion of general principles instead of practical details. It appears to us that there is one question upon which reform or non-reform almost entirely depends, and that is the question of "what constitutes NOVELTY?" What constitutes a publication? According to English law (Hindmarch on Patents, 1846, p. 108), "The importation of a foreign book into this country, containing a description of an invention, would not be sufficient to defeat a subsequent patent for it, unless the work was actually sold, and published to the public here, from the date of the patent. If, however, a single copy of a foreign work is deposited in the British Museum library, or in any other place to which the public can resort for information, any subsequent patent is invalidated." See also Baron Heurteloup's case, Webster's Reports, vol. 1, p. 553.

As a comment on this, we will quote the following:—Mr. Bennet Woodcroft was asked before the 1851 committee on the patent laws, "Have you prepared a complete series of the inventions connected with the steam-engine?—Answer: I commenced to write an analytical history of the steam-engine, and, to my great surprise, I found in 'Hero of Alexandria,' the whole of the elements of the steam-engine. I found every valve, the slide-valve, the clack-valve, and the spindle-valve, all in 'Hero of Alexandria;' and I found a metallic piston, working in a metallic cylinder."

According to paragraph 25 of the 15th and 16th Victoria, a patent, if granted for an invention patented in a foreign country, is invalid after the expiration of the foreign patent. It would thus appear that any old foreign patent is also invalid in England.

We will now try to ascertain what constitutes *novelty* in foreign countries. According to article 6 of the old law of 1839, an invention can be patented in the United States within six months after being patented abroad. The American commissioners also seem to require *absolute* novelty.

The law of patents at present existing in France is that of 1844. By articles 30 and 31 of that law, absolute novelty is required. According to article 31, "Ne sera pas reputée nouvelle toute découverte invention ou application qui, en France *ou a l'etranger*, et antérieurement à la date du depôt de la demande, aura reçu une publicité suffisante pour pouvoir être exécutée."

The different German states composing the Zollverein have a special law for each state. There is, however, an existing general convention between all these states. The following is a translation of Art. 1 of this convention:—"The States must only grant patents for really new and peculiar (eigenthümliche) things. A patent must not be granted for things that were in any way known before within the states of the Zollverein. In particular, a patent must be refused for anything that has been described *in a published work, inland or foreign*, written in German or any other language; supposing the thing to be described or illustrated in such wise, that it might be carried out by any expert. Each Government of the Zollverein is its own judge as to novelty or speciality of the invention to be patented."

Mr. Wedding, one of the Prussian patent examining commission, appeared as a witness before the committee of 1851. He stated, in answer to the question, "what proportion of applications are refused at present (1851)? There may be 400 or 500 applications made during the year; perhaps there may not be more than 70 or 80 patents granted." (We alluded some time ago to the fact of Monsieur Giffard having been refused a Prussian paten)t. This patent is, probably, worth £100,000 in England alone.) He was also asked: "What would be the law in the event of its being discovered, after a patent had been granted, that the invention or the process had been in use previously? Answer: Of course the party loses his patent right. In the *guarantee* (!) of the patent there are always some lines to say—as far as we are acquainted with it, it is new. We may get, bye-and-bye, the knowledge that this may not be a new invention; it may be described elsewhere, or some of our own countrymen may have *tried* to do it, or it may be executed already; therefore, the members are obliged to say—as much as we know, we regard this as new. No comment is needed on this!

The Austrian law requires a previous examination of a patent; but this examination is merely nominal; it gives no guarantee, and absolute novelty is required to make a patent valid. A Belgian patent is given without any examination, and at the risk and peril of the inventor. According to No. 5, article 24, law of 1854, a patent is invalid if it be described in a printed work previously to the granting of the patent. The Spanish, Italian, and Portuguese patent laws are similar to those of Belgium, all of them being framed somewhat similarly to the French law. The patent laws of Holland, Russia, and Sweden, are similar to those of Austria and Prussia. The patents have to pass an examination, but the passing of this examination does not save them from any subsequent attack on the score of want of novelty.

The above extracts will give the reader some idea how the patent laws of the different civilized countries bear *upon each other*, in respect to novelty. We are, probably, within the estimate when we assert, that there are 200,000 patents in the world fully described, and illustrated. Some of these are, no doubt, repetitions, from the same thing being patented in different countries. There are, however, many patents containing a number of different inventions. Such are some of the patents taken out under the old law in England. These are technically termed "omnibus patents," from the fact of there being as many different inventions wedged in, as a 'bus conductor can crowd into an omnibus on a rainy day. Even Mr. Woodcroft's indices are ineffectual in sifting them. As far as this is possible, however, the 50,000 English specifications are accessible enough. It has been impossible for Mr. Woodcroft to give proper headings to all the inventions under the old law. In the excellently managed patent office in Southampton-buildings, all the official foreign publications have been collected. The indices only of the French patents are complete. Only some of the French patents have been published. These select few were those judged at the time to be the best. Some of the most important have been omitted, thus affording a practical commentary on the principle of selection as applied to the "utility" of inventions. The American Commissioners' reports are curiously arranged, according to the fancy of each successive new Commissioner. Only the "claims" are given. There are also some meagre official accounts of the German, Italian, and Belgian patents. We will suppose that a determined patentee has waded through the 200,000 patents! This is not sufficient, however. An Alexandrian manuscript may turn up, as it did in the case we have have cited of Mr. Woodcroft's. Further intercourse with China or Japan may lead to a deeper appreciation of the fact that there is nothing new under the sun. The records of the British Museum, modern and ancient, in foreign or dead languages, have still to be examined before a patent can be obtained that will stand the test of *absolute* novelty.

For instance, we may even some day discover, by means of a recondite antiquarian process, that Robin Hood gave the original idea of a flat-fronted projectile. The main idea of the flat-fronted shot has lately been found to be embodied in an old English war-arrow. We may yet discover that Robin Hood invented this kind of arrow for piercing the breast-plates of the men-at-arms of the *late* sheriff of Nottingham!

If this difficulty of ascertaining the novelty be great in England, how much more so must it be in other countries! As we said before, there are probably more than 200,000 patents in the world. The public libraries are positively gorged with old works on machinery, full of the most ingenious arrangements. Would it be possible, we will not say for an individual, but for even a regiment of accomplished *savants*, to wade through such a mass of material? This test of absolute novelty is the plague-spot of the modern system of patents. It is this which renders property in invention so precarious, and often so ruinous. Very few patents can be received as really valid until they have passed the ordeal by fire of a court of law. In fact, there are now such a number of patents, that we are almost in the position the late Mr. Brunel wished for. He used to say: make patents cheap, and they will become so numerous that each patent will destroy the other.

The progress of a good invention has several stages, like Shakespeare's seven ages of man:—1, A man of observation or of genius sees a want or gap in current technical life, and he dovetails his idea into it. The invention is thus conceived, and it is then drawn out, say, on paper. 2, It is put into some demonstrable shape. 3, On being shown in a state of "bantling" to others, it is sneered at, unless the inventor be of an already-established reputation. It is made a butt whereon others can exercise their skill in finding objections. 4, It is at last elaborated by the parent, and on its being ocularly demonstrated that the thing is good, it is received as a "*fait accompli.*" 5, Like satellites round the sun, or, rather, like parasitic insects on an animal, swarms of evasions, copies, *soi-disant* improvements, and inland and foreign infringements are immediately hatched. 6, "Last stage of all that ends this strange eventful history," the invention is discovered to be old. Perhaps some elderly gentleman, in some remote part of the kingdom, proves on black and white, that he has done the thing before. *We* often look upon such assertions as a confession of folly. Some old patent is perhaps dug up, or some parchment is exhumed out of the depths of the British Museum, and the invention is shown to have been known in the time of our great-grandmothers. 7, The invention being now old, it must therefore die. Death-warrants are at once applied for in our courts of law. If the patentee has a long purse, as well as a long head, he is able to protect his invention. If not, it drops into the great maw of the public. An examination of the reports of the patent trials we publish in our columns, will show that three-quarters of the oppositions to successful inventions are based on questions of priority. The question of novelty always offers a formidable weapon to plagiarism and evasion. How would it be possible for *any* commission, however powerful in numbers and intelligence, to decide upon the absolute novelty of any patent? No doubt this crying evil is often met, at present, by the good sense of the judge and jury trying a case. As is well known, the bias of juries is generally for the patentee, and against pirates; not so, however, as between patentee and public. We will refer to a well-known instance.

According to the minutes of evidence before the 1851 Committee on the patent law, Sir David Brewster was asked: "Supposing a scientific man has an idea, and he does not think that it would be worth while to go to the expense of a patent to protect him in that idea, is not there the motive of fame, which would induce most scientific men to give to the public that idea?

The reply was: It depends very much upon the man. There are many instances of things being kept secret, and not published. In the case of the achromatic telescope, it was invented by a country gentleman of the name of Hall, who did not choose to take out a patent, but put the telescope into his drawer; Mr. Dolland got a patent for it afterwards. The instrument was found, after the death of Mr. Hall, to be the real achromatic telescope. It was decided that Mr. Dolland was not vitiated by the previous discovery of Mr. Hall, who had not made it public."

The Patent Law Commissioners now sitting have lately asked the Birmingham Chamber of Commerce, the following question amongst the others we gave in our last number:—"*Is it your opinion that there ought to be a preliminary investigation of a more searching character than that which at present takes place?*" To this we would reply, Yes.

The preliminary investigations should be very searching, but they should only go back fifteen or twenty years. There should be a law of limitation. "*All inventions and discoveries should be accepted as new, that had ceased to be worked in England for the last twenty years.*" This appears to be the only way to render a board of examiners at all practicable. Sir David Brewster was questioned before the Committee of 1851, as to how he proposed that the Board of Commissioners, the appointment of which he recommended, should be able to ascertain the novelty of an invention. He answered: "The Commissioners must make themselves acquainted with the progress of science and art during a certain period; it would not be necessary to go very far back. It would be very absurd to prevent any man getting a patent, because such a thing had been known, or even registered, fifty years before. I would hold the property of all ideas to be extinct after a certain time to be named, and after that time the board should make it their business to be acquainted with all those inventions and processes which have been since published and secured by patent."

Capitalists grumble at having to buy up intellect. There are hundreds of old patented mechanical arrangements, perfectly visionary twenty or thirty years ago, that could now be carried out with our present engineering facilities. Who could afford to put them into a practical shape, and to have them pirated the next moment? There can be no stronger argument in favour of patents than is afforded by this fact, a matter of continual occurrence, as every one knows, who has been engaged in practical life. The recent descision in the celebrated case "Betts *v.* Menzies," in the House of Lords, may be cited as carrying out this view.

Besides the merit which consists in first conceiving a new thing, then testing it by the light of science, and putting it into a practical shape, there are other merits and difficulties about inventing, no less great than the preceding ones.

These latter consist in fully seeing the value of any invention, in its application to the existing state of things. A sound appreciation of any new discovery or application requires a powerful and practised intellect, before success has given the stamp of current coin to the precious metal. Take the history of the steam engine. It is full of instances illustrating the difficulty of sound appreciation of any new discovery.

What would Watt have done without a Boulton? We all know what Smeaton once thought of the steam-engine. Take again the special developments of steam. What was the fate of Trevethick with his locomotive? The reception of George Stephenson by the quondam committee of the House of Commons is passing into a proverb. What were the fates of Symington in England, and Fulton in America?

To come to more recent times The steam fire-engines, now getting so largely into use, were invented and practically used by Mr. John Braithwaite, more than 20 years ago.

The patent of Nasmyth's steam hammer, by which he is said to have made £80,000, was invalid all the time he was working it. An older specification than his has been recently dug up. If this specification had unfortunately been discovered, during the time Mr. Nasmyth was working out his patent, should this gentleman have been deprived of the just reward due to his ingenuity? We might multiply these instances, even while confining ourselves to the steam engine.

Our proposition of defining as novel any idea that has not been used for the last 20 years, will no doubt be met with the following objections. It will be said that it is:—1, In contradiction to the principle of giving a patent as a reward for merit. 2, That giving a patent for an old invention would be a robbery of the public.

To the first objection we would answer that a patent is *not* granted as a reward for merit. The best proof of this consists in the fact that a patent is refused for a new principle, the thing the most difficult to discover. According to Mr. Webster, patents rest upon two principles, 1, That of just remuneration to the individual inventor; and, 2, That of promoting the public interest. The principle as recognized by the common law of this realm, was this:—He who shall introduce a new trade into the realm, or an invention tending to the furtherance of a trade, shall have a monopoly patent for a reasonable time, till the public shall learn the same. The means of instructing the public, under the common law, was by requiring the patentee to take apprentices. That was not a very practical mode, and it has been entirely superseded by the modern rule of the specification. It is required of the party, as a consideration for the monopoly he enjoys, that he shall give the public a distinct account of his invention in the nature of a specification, so that they may have possession and advantage of it when the patent expires.

To the second objection we would answer: Suppose that the public do not accept or neglect the teaching of an inventor for, say, 20, 30, or 50 years? Such an invention is practically lost to the public, to the mass, who require tangible, ocular practical evidence, before they will receive anything in science as a truth. An idea consigned to the Limbo of bygone patents is like a seed or root buried with an Egyptian mummy. It requires to be dug up, to be planted and watered by an intelligent hand, before it will take life and flourish. Is it to be expected that any man will go to the trouble, the expense, the risk, of thus giving new life to a forgotten scheme without expecting some compensation for his exertions?

We do not suppose that the opinions we have expressed will meet with favour in all quarters. It would be very difficult for any opinion to do this. Everybody has some special "patent medicine" for infusing new life into our petrified patent law. However that may be, the spark of truth is often elicited from the shock of discussion.

We hope that the Patent Commission now sitting will take plenty of evidence as to the working of the patent laws of foreign countries. A sound examination and comparison of results of the different systems ought to afford a good basis for legislation. It would be like an examination into the results of a series of experiments instituted for the elucidation of some question of science.

II.

INTERNATIONAL EXHIBITION. JURORS' REPORT.

Class X., Section A.—Civil Engineering and Building Contrivances.

II.—Harbours and Docks.

(*Continued from page 414.*)

The new naval graving docks of Castigneau, at the arsenal of Toulon, as designed by, and constructed under the direction of, M. Noel, inspector-general of bridges and roads, director of maritime constructions at Toulon, are remarkable for their extent, and the great natural difficulties which attended their construction, all of which were overcome in a very masterly manner by the engineer and his assistants, for which they are entitled to considerable credit. The soil upon which these docks are built is of a soft alluvial nature, and, there being no rise of tide, it was necessary to fix the floors of these docks at the full depth required to float the largest vessels of war; the soil, moreover, was so porous, that a single coffer-dam in the sea in front of where the docks were to be constructed would not have sufficed to have kept the works dry while they were proceeding; it therefore became necessary to enclose the whole space with a double row of piles, filling in the space between them with concrete, as fast as the earth was dredged out; this concrete subsequently serving the additional purpose of forming an important part of the side walls of the intended docks. The great mass of earth from within the centre space, enclosed by the double row of piles before mentioned, was then removed by excavating down to the proper depth, and the bottom of the dock was founded upon a bed of masonry and concrete, upon piles; the whole of the bottom and sides being then faced with masonry throughout; thus three substantial and effective graving docks for the largest vessels of war were completed in a novel and successful manner. The dimensions of all three docks are 102¾ metres, 121 metres, and 166½ metres in length, with a general width of 22 metres, and a depth of water on the cill of 9½ metres. To M. Noel, inspector-general of bridges and roads, a medal has been awarded for these very extensive works, methodically executed by simple and certain means, comprehending even the smallest details.

The graving dock at the dockyard at Rochefort is an important work; it is 134 metres in length by 22½ metres wide, with a depth of water of upwards of 8½ metres at high water; thus a vessel of 125 metres long by 21 metres wide can be accommodated. The foundations were of a difficult nature, but they were very satisfactorily accomplished, and the general work is very successful. For this work, executed under circumstances of difficulty, a collective honourable mention has been awarded to M. Garnier, engineer-in-chief of bridges and roads, to M. Angiboust, engineer of bridges and roads, and to M. Charvin, resident engineer.

In connection with this subject must be mentioned the ingenious mode of blasting the submerged rock of La Rose, at the entrance of the Port of Brest. This rock, which was of compact gneiss, with veins of quartz, was entirely removed by repeated explosions of charges of 100 to 120 lbs. of gunpowder, in stone jars, which were placed at high water, by divers, upon the parts of the rock to be shattered. These were fired by Bickford's fuses, enveloped in gutta-percha tubes. The masses of rock thus shattered were removed at low water. By this means, 20,000 cubic metres of rock were removed at depths varying from 7 to 15 metres below the surface of the water, at a cost of about 35 francs per metre. The work was very satisfactorily accomplished under the direction of M. Dehargne, engineer-in-chief of bridges and roads, by M. Verrier, engineer of bridges and roads, to whom a collective honourable mention has been awarded for this successful blasting of a submarine dock without bore-holes.

The coffer-dam for the construction of the dry dock, at the arsenal of L'Orient is nearly on the same system as that employed for the foundation of the quay at the port of St. Nazaire; by means of a series of hollow square masses of masonry, construdted and sunk independently of each other, and then united and filled in solid with rubble-work and hydraulic mortar. For this good application of an ingenious system, applicable in peculiar situations, collective honourable mention has been awarded to M. Harduin, engineer-in-chief, and M. Le Bouedec, engineer of bridges and roads. to whose skill and attention the successful result is due.

To the New South Wales Government has been awarded a medal for the great utility of the Fitzroy Government Dock; and to Mr. Hunt, also of New South Wales, a medal for the public benefit arising from the dock constructed by him.

Before leaving the subject, the floating docks of Sunderland, designed by, and constructed under the direction of, Mr. John Murray, C.E., must be adverted to. The general plan of these docks is a good example of giving a double entrance to a port, affording excellent dock accommodation in the position required, and combined with powerful scouring sluices, for keeping the entrances open; all these most essential objects in the design and construction of a good port are well combined at Sunderland, and a medal has been awarded to Mr. John Murray (United Kingdom, 344), for the merit of the design and the execution of the work.

The application of the hydraulic press for the purpose of raising great weights has long been known and adopted in numerous instances, and latterly very extensively by the late Mr. Robert Stephenson, for raising the large tubular girders composing the Britannia and Conway bridges; a similar idea has been conceived by Mr. Edwin Clark, C.E., and applied in a very ingenious manner for raising floating pontoons, which are made to answer the purposes of dry docks for constructing, examining, or repairing vessels. The operation is very simple. A space of water is enclosed, sufficient for the required pontoon, or floating dock, around which are firmly fixed a number of hollow iron columns, in each of which is a hydraulic press and piston, having chains attached to them; these chains are attached at the other end to transverse wrought-iron girders at the bottom of the inclosed water space; the wrought-iron pontoon, which is to carry the vessel, is then floated between the columns, and sunk on to the girders by admitting water into its compartments until it rests upon the bottom of the inclosed water space; the vessel intended to be repaired is then floated over the pontoon, and is placed accurately above it by means of guides; the girders and pontoon, with the vessel upon it, are then raised by the hydraulic presses, worked by a steam engine and pumps, which act upon the pistons and the chains attached to them, to the cross girders, and as the pontoon rises with the vessel upon it, the water runs freely out of the compartments of the pontoon, and, when the whole is clear, the valves are screwed down from the inside, and the pontoon and vessel are floated away into a basin, and another pontoon is placed in readiness for another similar operation, which generally occupies, for a very large ship, about forty-five minutes. Thus one hydraulic apparatus, with its necessary upright columns, cradle, and basin, or dock space, will answer the purpose of as many dry docks as there are pontoons; and when a vessel has been repaired, the supporting pontoon is again floated over the transverse girders, the valves are opened, and the pontoon sinks gradually, thus leaving the vessel afloat and ready to be taken away. This ingenious adaptation of the hydraulic press is calculated to be very extensively useful in many localities, and to Mr. Edwin Clark, E.C. (United Kingdom, 2,255) a medal has been awarded, for the novelty and general utility of the application.

A large wrought-iron floating dock has been designed, and is being constructed for the Spanish Government by Messrs. G. Rennie and Sons. It is 350 ft. long, 105 ft. wide, and 37½ ft. high, and it will draw, when a vessel of the largest class is in it, about 10 ft. This dock is constructed nearly upon the same principle as the old Dutch Caramel Floating Docks, but is much more complete. It is hollow, is divided into compartments, and is emptied with pumps, worked by a steam-engine placed on the floating dock, so that either by admitting, or by pumping out the water, it can be lowered or raised as may be required, and it can thus be rendered available for any class of vessel. To Messrs. G. Rennie and Sons has been awarded a medal by the Jury of Class XII. for the completeness of the arrangements and the good workmanship of this important construction.

Floating docks upon this as well as upon Clark's system are no doubt very valuable, but it may be a question whether they are likely to supersede the slip system, or that of drawing the vessels out of the water, which can be made equally valuable in certain localities. It is true that the latter system requires that the lower end of the slip should be carried down to the greatest depth, at which a light ship of the largest class can be brought to the lower end of the slip; this cannot be taken at less than sixteen to twenty feet, and to effect this in seas where there is no tide must be attended with considerable expense; and laden vessels cannot, as in Rennie's and Clark's systems, be drawn up, examined, and lowered again within a few hours. Anything by which the old system of heaving down vessels of the ordinary class can be avoided merits attention, as that process is always attended with expense, inconvenience, risk, cost, and delay. The re-introduction of floating docks, on improved principles, has also induced attention to Morton's patent slip, which is now again being brought forward with considerable improvements. All these systems are valuable and useful, and can be brought into the public service where the fixed dock system is considered too expensive, or where the localities are not calculated for such extensive and weighty structures.

III.—Moveable Weirs.

Moveable weirs, or dams for penning up water in rivers, during summer and dry seasons, may be said to be a modern invention, chiefly practised in France, although they somewhat resemble the ancient rude flushing weirs adopted in Great Britain for rendering the shallow parts of rivers navigable during dry seasons. M. Poirée, inspector-general of bridges and roads, has, with great skill, introduced this valuable system, which is the origin of all the improvements since adopted; and in various rivers in France these weirs are applied with complete success; they are either self-acting, or can be lowered, or removed, with the greatest facility, so that the quantity of water in a river can be regulated to the greatest nicety, either for navigation, irrigation, or domestic purposes, whilst every facility is afforded for the discharge of floods. This system may be applied with advantage to many of the rivers and streams in Great Britain.

At the arrage of La Chainette, on the river Yonne, near Auxerre, it has been well applied, and for it, to M. Poirée, inspector-general of bridges and roads, a medal has been awarded for the application of numerous improvements, and to M. Cambuzat, engineer-in-chief of bridges and roads, and M. Marini, resident-engineer, collective honourable mention for the good arrangements and construction of these works.

For the barrages, or weirs, with panel sluices, executed on the upper Seine, a new mode of closing the navigable passes, and of raising the level of the water by ingenious and well-conceived arrangements, insuring a certain and rapid action, as demonstrated at the barrage of Conflans, a medal has been awarded to M. Chanoine, engineer-in-chief of bridges and roads.

And for the new system of moveable panel sluices for the side-cuts of moveable weirs, for the ingenious and simple arrangements and construction, whereby the operation of raising, or of lowering the sluices is rendered almost instantaneous and self-acting, being performed by the action of the water as directed by the raising or the lowering of two paddles worked by one man, a medal has been awarded to M. Louiche-Desfontaines, engineer-in-chief of bridges and roads, as the inventor of this improved system, and to M. Cölin, honourable mention for the excellence of the execution of the model, which exhibits so perfectly the construction and the mode of working. The self-regulating sluice invented by M. Chaubart must also be mentioned for its ingenuity, and for its applicability in many localities.

With this part of the subject must be mentioned the ingenious system devised for carrying the mountain torrent of the Libron on a level across the Canal du Midi. This torrent, generally dry, is subject to sudden flushes from storms, which bring down masses of *debris*, which would fill up the bed of the canal. It became, therefore, necessary to carry the torrent freely across the canal, which was accomplished by having alternative divergent channels, each of which on both sides had sliding troughs, which could be pushed across to form canals for the torrent when requisite, and be removed for the passage of boats, or when the torrent was dry; the waters of the torrent being directed and governed by stop-gates. The details of this simple contrivance were most ingeniously devised and successfully executed by M. Magues, engineer-in-chief of bridges and roads, and M. Simonneau, resident engineer, to whom collective honourable mention has been awarded for this work.

IV.—Compensating Reservoirs, etc.

With regard to the fourth division—the compensating reservoirs for supplying rivers and streams during summer and dry seasons. This is a most important and valuable system, and it has now become an absolute necessity, as, in consequence of the present superior system of land drainage, a greater proportion of the rain-water which falls upon the land is discharged into the rivers, and is carried off almost immediately after it falls, so that in summer and in dry seasons the lands frequently suffer for want of moisture; the navigation is impeded, and the supply of water for irrigation and for domestic purposes is diminished. Moreover, as sewage matter is now generally discharged direct into the nearest water-courses, the small quantity of water in them in times of drought becomes polluted to such an extent that it is unfit for use, whilst the malaria arising from it is liable to produce disease. The great object, therefore, is to obtain a thorough command of water, so that the land may be properly drained, the sewage be carried off effectually, and that there may be at all times an ample supply of good fresh water for navigation, irrigation, and domestic purposes. A system of compensating reservoirs, established in the most convenient places, along the line of, or adjoining the valleys, through which rivers pass, so that the desired quantity of water may be stored in them during the periods of rainfall, and be discharged again by means of proper sluices, into the rivers and other channels, where required during the summer and dry seasons, is evidently the only proper plan to obviate the serious evils above mentioned, and to combine all the desiderta of complete drainage, sewage, navigation, irrigation, and domestic water supply. This system was largely adopted by the ancients in the valley of the Euphrates, India, and elsewhere, and it contributed largely to the wealth and prosperity of those countries wherein it was practised. It redounds greatly to the credit of the French Government and their engineers that this system has been introduced into France with such complete success in many places. It is excellently exemplified by models of the compensating reservoirs of Les Settons, for the service of the river Yonne, for which useful and well-executed work collective honourable mention has been awarded to M. Rozat de Mandres, engineer-in-chief of bridges and roads, who designed, and to MM. Olry de Labry and Marini, resident engineers, who executed the works. Also honourable mention to M. Veron Duverger, engineer-in-chief of bridges and roads, and to M. Sciama, resident engineer of the Reservoir of Montaubry, for the service of the Canal due Centre, in Burgundy, for the excellence of the design and the satisfactory execution of the works.

The introduction of this system into Great Britain, has long been advocated by English engineers, who have devoted their attention to the subject, and it cannot be much longer delayed, as works of this kind are now imperatively demanded, both in a sanitary and economical point of view.

The irrigation canal of Carpentras, in the department of Vaucluse, deserves notice as a most useful and successful work, carefully designed and executed by MM Perrier and Gendarme de Bevotte, engineers-in-chief of bridges and roads, and M. Conte, resident engineer, to whom a collective medal has been awarded by the Jury of Class IX.

V.—SEWERAGE.

In connection with this subject must be mentioned the improved systems of sewerage now being introduced in London and in Paris. They are entitled to much consideration, and demand a more lengthened notice than is consistent with the limits of this report.

The system of sewerage of Paris has hitherto differed essentially from that of London in still retaining for the most part cesspools beneath the court-yards of the houses: the more copious use of water has, however, necessitated a change, and the municipality is proceeding to provide for the new order of things by the construction of sewers beneath the streets, and combining with them collecting reservoirs, and a general distribution of water, comprising an ingenious self-acting method of cleansing the sewers, whilst introducing a more comprehensive and general system of carrying off the water. This combination is well exhibited by a plan of the sewers of Paris, and a model in section of the sewer of the Boulevard Sebastopol, with a plan of the water service of Paris, and a model in section of the reservoir of Passy. This latter work merits careful study, as does also the collection of apparatus used tn the distribution of water throughout the city. The map of this distribution conveys very interesting information; and the model of the great artesian well of Passy, executed by M. Kind, under the direction of MM. Alphand, engineer-in-chief, and Darcel, engineer of bridges and roads, merits every eulogium.

These exhibited great knowledge of the subjects, careful study of the means of meeting the wants, and of carrying out the works gradually, without undue interference with the working of the present system; and for this and the general intelligence exhibited in the design, a collective medal has been awarded to M. Belgrund, engineer-in-chief of bridges and roads, and to his assistants in the execution of these important works.

There were also exhibited, in the French department, several other collections of maps, plans, and models of the system of sewerage adopted in Paris, many of them possessing great interest. The map and atlas of the Catchweter sewers, or, "Egouts Collecteurs," are full of interest, as showing how early that system was recognized and adopted, and the carefully designsd progressive steps taken toward establishing one uniform system. The details are most interesting, and the works reflect infinite credit upon M. Michal, inspector-general of bridges and roads, upon whom devolves the general direction, and upon M. Belgrand, engineer in-chief of bridges and roads, who has charge of the sewerage, having under him MM. Rozat de Mandres and Vallée, engineers of bridges and roads, who have the actual superintandence of the works.

The great collecting sewer of Asnières was constructed under these auspices by M. Delaperche, engineer-in-chief of bridghs and roads.

The sewer of the new Boulevard Sebastopol previously mentioned was more immediately directed by M. Rousselle, engineer of bridges and roads.

A very interesting map of the distribution of water within Paris gave all the details of the supplies, the number of fountains, &c., and of the dimensions and length of the mains, as drawn up under the auspices of M. Michael and M. Belgrand.

Two very interesting and well-executed albums of maps and plans showed all the public squares, gardens, and promenades of Paris, including the Bois de Vincennes and the Bois de Boulogne, where so much ornamental gardening had been done so effectually under the immediate direction of the present Emperor of France. These works, which merit all praise, have been executed by M. Alphand, engineer-in-chief of bridges and roads. MM. Grégoire, Foulard, and Darcel, engineers of bridges and roads; M. Davioud, architect; and M. Barillet-Deschamps, head gardener, acting under the direction of M. Michal, inspector-general of bridges and roads.

The history of the numerous attempts to improve the system of sewerage of London is so well known that it is not necessary to do more than allude to the great works now in progress on both sides of the Thames. The published reports give the details of all the arguments, investigations, calculations, and plans of Mr. Morewood in 1845, Mr. F. Forster in 1851, Mr. R. Stephenson and Sir W. Cubitt in 1854, Mr. J. Simpson, Captain Galton, and Mr. T. E. Blackwell, in 1857, and Messrs. G. P. Bidder, T. Hawksley, and J. W. Bazalgette, in 1859; whence has resulted the comprehensive scheme of works now in course of construction under the direction of Mr. J. W. Bazalgette, C.E., engineer to the Metropolitan Board of Works, to whom an award of a medal would have been recommended had it been compatible with the rules laid down by the Royal Commissioners, which prohibit any award to a member of a jury.

A complete set of plans and documents descriptive of these extensive works was exhibited (United Kingdom, 2,369), and the members of the jury were enabled to judge of their importance by an inspection of the works themselves in their fullest extent.

(To be continued.)

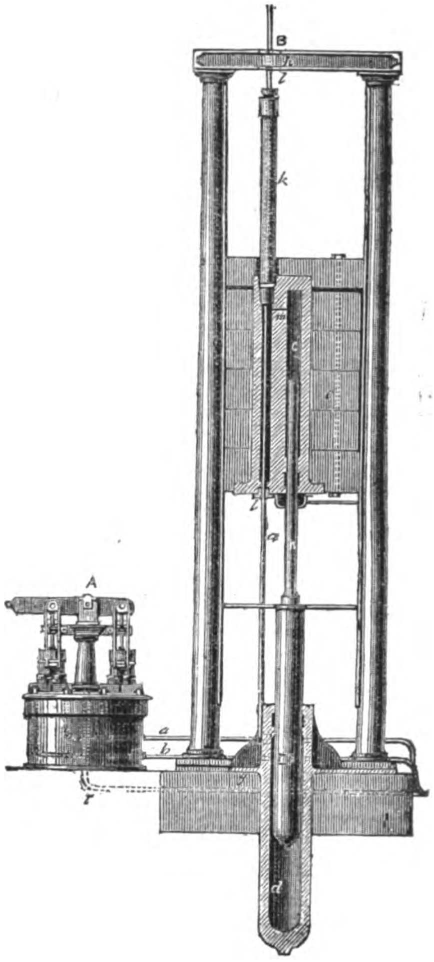
SAMUELSON'S IMPROVEMENTS IN THE WORKING OF HYDROSTATIC PRESSES.

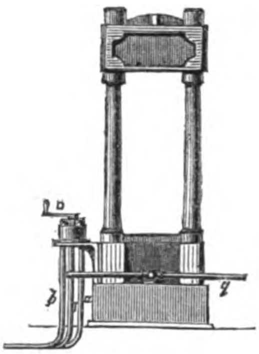
THIS invention seems to be an application of the idea of the accumulator (used by Sir William Armstrong for his water cranes) to hydraulic presses. It is patented by Mr. Alexander Samuelson, whose well-known firm at Hull exhibited a connected series of oil-pressing and oil-cake machinery, in the western annex of the International Exhibition. It relates to a peculiar arrangement of accumulating apparatus to be used in combination with hydrostatic presses for crushing fatty substances, and consists essentially in the adaptation to such presses of an accumulator so arranged that one weight produces two distinct pressures, one considerably greater (by preference about nine times greater) than the other. This is effected in the following manner:—There is a lower cylinder containing oil, water, or other liquid; in this cylinder a ram is fitted in the usual manner. Above this ram, and forming a continuation of it, is an upper ram about one-third the diameter of the lower one; this smaller ram is inserted into an inverted cylinder, also containing oil, water, or other liquid, and which cylinder is imbedded in, and forms part of the weight or load. There is no communication between the two cylinders, each being charged by its own pump or pumps through proper pipes; these pipes also communicating with the stop boxes attached to the presses. A stop box may be fitted to each press, or one stop box may communicate with and actuate several presses. Each stop box is fitted with three ordinary cone valves, namely, one communicating with the low-pressure cylinder of the accumulator, one with the high pressure, and a third to discharge the presses. The spindles of these valves have rather coarse-pitched threads upon them working through the packing glands as nuts, and above these threads, on the tops of the spindles, are cams actuated so as to open and shut the valves by a central cam and handle, and so arranged, that by one revolution of this central cam all the valves are successively opened and shut, as required, in the operation of oil expressing.

The engraving represents a partial sectional elevation of the improved accumulator, showing its connection with the working pumps and with a series of presses. In the engraving only one is shown.

A represents the working pumps; B is the improved accumulator; C, a hydrostatic press; and D, a peculiar form of stop box and mechanism for working the valves, hereinafter fully described.

The pumps may be of the usual construction, but Mr. Samuelson prefers to employ the arrangement for which letters patent were granted to him in 1862, (No. 203). They communicate direct by means of the high and low pressure pipes *a* and *b*, with a peculiar stop box. A vertical branch from the high pressure pipe *a*, which is supplied from the small pumps, leads to the small cylinder *c* of the accumulator, whilst the low-pressure pipe *b* (supplied from the large pumps) communicates by a short lateral horizontal branch with the lower and larger cylinder *d* of the accumulator; *e* is a heavy weight or series of weights, inside of which is fitted the small inverted cylinder *c*; it is guided in its ascent or descent by the vertical guides *f*, *f*, fixed on a strong bed plate *g*, and braced together at the top by the cross beam *h*. The high-pressure pipe *a* passes through a stuffing box *i* in the bottom of one side of the casting in which the small cylinder is formed, so as to allow of the rise and fall of the weight, with its contained cylinder *c*, along the pipe *a*, which passes through the casting before referred to, and through a vertical tube or cylinder *k*, secured to the upper end of the casting a packing gland *l*, forming a liquid-tight joint at the upper end of the tube. One or more small apertures are made in the side of the pipe *a*, through which, and through the small





passage *m* in the casting, the oil or other liquid employed is forced into the small inverted cylinder *c*, so as to act upon the small ram *n* working inside it. This ram forms a continuation of the larger ram *o* working inside the larger cylinder *d*, which may be cast in one piece with the bed plate *g*. It will thus be seen that the cylinders *c* and *d* of the accumulator have no connection with each other, being supplied from the small and large pumps respectively.

D is the body of the stop box, into the bottom of which are made four vertical passages, namely, one central passage in connection with the press pipe, and three outer passages in connection respectively with the high-pressure pipe *a*, low-pressure pipe *b*, and waste pipe *r*. These three outer passages are respectively closed by the valve spindles, and all communicate by radial passages with the central or press pipe. A screw thread is formed on the upper end of each valve spindle, and works through the packing gland as a nut, so that by partially rotating each spindle it will be raised or lowered, thereby opening or closing the valve accordingly. The cams are severally fitted on to their respective valve spindles, and are operated upon successively so as to open the valves by a wiper formed on the boss of the horizontal lever handle turning on a centre. A stud projecting down from the under side of the lever handle, and pressed forward by a spring, serves to reverse the motion of the valve spindles, and close the valves as the handle is rotated. The object of the spring is to force the stud over the points of the cams, and thereby ensure the effectual closing of the valves.

Proceedings of Societies.

INSTITUTION OF ENGINEERS IN SCOTLAND.

First Meeting of Session, 29th Oct., 1862.

Results of an Experimental Inquiry into the Comparative Tensile Strength and other Properties of various kinds of Wrought Iron and Steel.

BY MR. DAVID KIRKALDY.

(*Continued from page* 418.)

In the discussion which followed—

Mr. Walter Macfarlane said it was well known to all practical workers in steel and iron, that if they attempted to temper some kinds of steel articles in water they cracked; but that if they did the same thing in oil there was not the same danger of doing so. He did not know whether Mr. Kirkaldy had given, or could now give, an explanation of the cause of the increased strength of steel when tempered in oil, as compared with that tempered in water? He would like to know whether the fibre altered, or what tended to produce the result.

Dr. Macquorn Rankine remarked, that Mr. Kirkaldy disavowed in his book any attempt to explain the changes which took place in steel when plunged into water or into oil.

Mr. Macfarlane said he thought there was an absolute necessity for their getting at the cause of that important result.

Mr. Kirkaldy, in answer to the president, had nothing further to say upon the point.

Mr. D. More said that Mr. Kirkaldy invited "special attention to the practical use that may be made of the new mode of comparison introduced by him, viz.: the *breaking strain per square inch of the* fractured *area of the specimen, instead of the breaking strain per square inch of the* original *area.*" That seemed to be the principal point hinged upon, as it was given in *italics*. Now, he did not think it was even the breaking strain of the *fractured* area that must be considered, for after the iron was broken it drew out a little further. This sort of posterior action was shown in some experiments made by Dr. Rankine and himself in regard to iron and also brick. They found, in crushing the brick, that it withstood a considerable force, and afterwards crumbled away with a less force, thus showing that the breakage had really taken place before the brick had commenced to crumble away. In experimenting with an iron bar, it was observed that the iron drew out and became narrower at one part (as he showed by a sketch on the board) until the strength of the material was overcome. Then, immediately on the iron beginning to break, it drew out before it was finally completely separated, so that the fracture took place when the bar was a little bigger than it finally became. He thought that the truth lay between the two areas—the original and the fractured area.

Mr. Kirkaldy said he had given the stretched area also in his tables, so that parties could judge of it for themselves. The three areas were given—the original, the stretched, and the fractured areas.

Mr. W. M. Neilson remarked that Mr. Kirkaldy's book was a mass of *data* from which to deduce results. He thought it was a very excellent thing that Mr. Kirkaldy had confined himself to giving facts, which would cause his book to be much more relied upon. He believed that Mr. Kirkaldy wished to lay his facts before the Institution for discussion, and that he would not be displeased, although they pulled them about as they liked. Regarding the effects of frost upon iron, upon which point he had never himself been quite clear, it appeared that frost did not effect the strength in a direct strain; but he had always had an idea, that perhaps not the drawing strain, but the breaking strain, was very much affected by frost. They all knew the fear they had of using chains in frosty weather. Now, he supposed that the strength of the chain links was very much diminished by the frost, and that the links broke not so much by direct tension as by a breaking strain.

Mr. Kirkaldy said his experiments on the influence of frost were all made with specimens taken from one bar. He regretted that the weather changed before he could carry out his intention of repeating these experiments with bars of various qualities. As the bar experimented upon happened to be of very good quality, perhaps they ought not to draw general conclusions from its behaviour.

Mr. W. Simons said that in the operations attending upon the placing of a thousand-ton ship on a ship-dock, during one frosty night he had seen three rods 3½ in. in diameter, broken, so that they had to stop and put fires to all the rods and joints, and after that none of the rods broke. In the International Exhibition, he had observed a very good specimen of Swedish iron, which some of the other members might also have seen, which was all crumpled like a hat, it being the bow of a steamer after collision. He did not believe that any Scotch iron would have stood such a test. He was of opinion that the result of Mr. Kirkaldy's investigations would be, that the present system of shipbuilding would be found to be entirely erroneous, and that for the future iron would be used in shipbuilding with its longtitudinal fibre placed in the direction of the most constant strain, a principle which had hitherto been ignored in marine construction.

Mr. B. Connor said that some very interesting experiments, which had not been published, had been recently made by Messrs. Naylor and Vickers, at Sheffield, with a view of testing steel, so as to ascertain the best suited for railway axles and tyres. They had found that the material best suited for axles was the worst for standing great tension. They found that steel, which could bear only 35 tons of tension, was the best for journals. They tried steel with 15 cwt. falling from 1 ft. up to 36 ft. The tensional strength of the steel was then increased so as to stand up to 69 or 70 tons, but it broke with the weight falling one-third of the space, and with less than one-half of the weight; and so that that which stood the greatest tension broke with the least concussion. He thought that between the highest and the lowest qualities of steel there was only a difference of one-fourth per cent. of carbon.

Mr. Kirkaldy thought that these experiments supplied strong reasons for taking the stretched and fractured areas into account.

Mr. B. Connor did not think the steel with the greatest amount of carbon, that broke almost short off, would show nearly so great a difference between the fractured and the original areas as the soft steel.

Dr. Macquorn Rankine concurred in what Mr. W. M. Neilson had said as to the very valuable collection of facts, most of them entirely new, which Mr. Kirkaldy had given in his book. It was a storehouse, from which they could all draw materials, and form their own conclusions upon them. Mr. Kirkaldy had very fairly described those facts, and it was the better that he had not set up any hypothesis upon them. One of the particular things which he (Dr. Rankine) remarked was, that the experiments of Mr. Kirkaldy seemed to point to the conclusion, that a process which many supposed to take place, namely, a change from the fibrous to the crystalline structure, had no real existence; and that the same piece of iron would show a crystalline or fibrous appearance accordingly as it was broken by a stroke or a strain. He came to the same conclusion himself nineteen years ago by experimenting on the fracture of railway axles, which when fitted up seemed to have been quite strong enough. He collected the broken-off journals of such axles; but he was sorry that he could not now produce them, as no means had been taken to prevent the ends getting rusty. But he had made full-sized drawings, coloured from nature, of the more remarkable of them, which he presented to the Institution of Civil Engineers, along with a paper, an abstract of which was published; but the drawings were not published, and remained at that Institution, where they could be seen by any one. He still, however, possessed the originals of those drawings; and if it would be agreeable to this Institution to see them, he would produce them at a future meeting. Of course they were not so satisfactory as the original specimens, or as Mr. Kirkaldy's; but unfortunately the originals had been spoiled by rust. He got the journals of axles that had run two or three years, and had then broken off spontaneously, and almost every one of these showed a fibrous fracture, with here and there a crystalline spot. There was invariably a crack which had eaten in from the shoulder of the journal, and which was perfectly imperceptible until after the fracture took place. The crack seemed to have gone on until it had reduced the original diameter of the journal to about one-half, and then the axle snapped; but it always presented a fibrous fracture, whilst if the same journals were broken off with the blow of a hammer, they presented crystalline or granular fractures. Accordingly, he had ever since thought it probable that a change from fibrous to crystalline, as supposed, was an erroneous hypothesis; and he believed that many other persons had come to the same opinion, and he was glad that Mr. Kirkaldy's experiments corroborated it. An important point in those experiments was the calling attention to the comparison between the fractured area and the load that caused the piece to give way. Every one knew before, that bars of iron would draw out, especially if soft, before giving way; but never before Mr. Kirkaldy had any one accurately measured the final area to compare that with the load. He thought that there was a great deal in the principle Mr. Kirkaldy laid down as to testing the quality of iron, by the comparison of the breaking strain with the fractured area; but he would not go so far as Mr. Kirkaldy and say that it was the most accurate test, although he had no doubt it was better than comparing the original area with the breaking load. The experiments of Mr. Kirkaldy had substantiated results that had been anticipated by theory. For example, it was a result of theory that the form of the longitudinal section influenced the breaking load per inch of area. Experimentalists, however, had not taken that into consideration before. Experiments were made upon the tenacity of bars that were for a long distance of a uniform diameter, but there had been experiments made with bars shaped so as to have an increasing diameter on both sides of the middle part (as he pointed out on the board), and the result was a great apparent increase of strength. It had been perfectly well understood by writers on the theory of elasticity, that the shape referred to must give apparent increased strength to the narrow portion of the area, as the wider parts on each side resisted the tendency to draw out, which was not the case with the parallel bar. Experimentalists, however, had not taken this into account until Mr. Kirkaldy took it up and arrived at the results detailed in his book. Mr. Kirkalday showed that the resistance of steel rivets to shearing was about a quarter less than the tenacity of the steel. That, also, was anticipated by theory. There was one very important point upon which Mr. Kirkaldy made some remarks, namely, as to the factor of safety—the ratio in which the breaking load ought to exceed the working load. Mr. Kirkaldy considered that the working load per square inch of the original area of the piece should be a certain percentage of the breaking load per square inch of the contracted area at the instant of being broken. He (Dr. Rankine) concurred in Mr. More's opinion, that the truth lay between the extreme views. He thought it would be going rather too far to make the working load per square inch a certain fraction of the breaking load per square inch of the fractured area. He might call attention to experiments made on the strength of steel by Prof. Tresca, of the French Government Corps of Engineers. They were made upon bars of steel cut out of boiler plates, and they showed the gradual elongation of the bar with the gradual increase of the load. The results were represented by a curve (of a kind sketched on the board by Dr. Rankine), the abscisses of which represented the loads, whilst the ordinates represented the elongations due to the loads. It was found that as the load was increased, the elongation increased at a uniform rate, until it reached a certain point, when there occurred a great increase in the rate of elongation, which was not quite sudden, though nearly so; and there resulted a curve, the early part of which proceeded in a nearly uniform direction, and which merged by a quick bend into a portion proceeding in a different direction corresponding to the more rapid elongation. Now, he thought the point where the change in the curve of elongation occurred was that at which the strength of the material had been overcome. It was very probable that the drawing out, which was so conspicuous in Mr. Kirkaldy's experiments, began at that point, and that the greatly-increased curve of elongation showed that the breaking had begun, and that the bar would break if the same load was simply put on it several times, without being increased, as was seen in Mr. Fairbairn's experiments. The experiments of this class was very interesting, taken in connection with Mr. Kirkaldy's experiments. He thought, then, that the best test of the quality of the material was the strain at which the sudden change of the curve of elongation began; or, if that supposition of his was right, the point at which the drawing out of the fibres commenced. If they could only make experiments so precisely as to measure the area of the bar at the instant of change, and compare it with the load, and take the corresponding strain per square inch, they would get at the true strength of the material; it would give a result between that of the old method and that of Mr. Kirkaldy's method. But although it was very desirable to obtain such experiments, yet there were difficulties in the way of performing them upon the immense number of materials that Mr. Kirkaldy had experimented upon. The Institution could not be too grateful to him for his labours, for he had collected a mass of facts which were of the highest value in a scientific and practical point of view.

Mr. James Russell would like to notice one proposition in Mr. Kirkaldy's treatise as to the appearances presented by the bar fractured when the fracture was made suddenly or slowly. It appeared that iron broken very slowly had a fibrous appearance, whilst that snapped off was crystalline. They all knew that if they wished to judge of the quality of iron in a rough way, they would break it probably over the anvil and look at the fibre. They found that bars broken in the same way presented very different appearances. They also found that some of the bars broken by Mr. Kirkaldy were half fibrous and half crystalline. Now, if the appearance of the fracture was no sure test of the quality of the iron, then they were put in a very awkward position as to judging of any iron that came under their notice to apply to various purposes. He dared say that it would agree with all their experience that iron had been judged by the appearance of the break. It was also known that a chain working on a crane might have sustained great loads for a long time, and yet break with a very much lower strain, and the broken link have a very crystalline appearance. A case came under his own notice where the top chain of a Derrick crane bore a heavy strain, and yet broke with a third of the weight that had been on it previously, and the link presented a very crystalline appearance. He hoped other members of the Institution would make a few observations on this important matter.

The President asked what was the state of the weather when the rod broke?

Mr. James Russell dared say they had seen them break in all kinds of weather; but uniformly when the link of a chain broke with a comparatively light load, it was more crystalline in appearance than other links that stood the test. For instance, they might take one bar and give it a blow, bending it only, whilst another would, with the like blow, snap at once like cast-iron. They were in the habit of saying that the one that bended was fibrous, and the one that snapped was crystalline.

Mr. Faulds could not look on a crane chain being broken with a third of its previous load as a criterion by which they could judge of the strength of iron, for a careless man by giving it a jerk would bring it down. But with reference to breaking iron, so as to appear fibrous or crystalline, any smith could take a bit of the best iron and break it, either crystalline or fibrous, as he choose.

Mr. W. Macfarlane would call attention to another phase of the question besides the quality of the material. They must not lose sight of the fact that some firms turned out better work than others, although using the same materials, and that induced him to call their attention to the annealing of iron. The strength of iron was very much reduced by the breaking of the skin, so that the strength of a finished shaft was less than when it left the forger's hands. In articles of great value, when the safety of many lives rested upon the security thereof, it occurred to him that it would be well if wrought-iron were annealed. He would like to know whether any extensive producers of such articles had made experiments on the annealing of iron work; and, further, what would be the expense if turned shafts were annealed or tempered in oil. His impression was that the same results must follow as with cast-steel, and that the strength of the material would be very much increased by the annealing or by the tempering process of oil—these two modes of treatment being quite different in their results.

Mr. Faulds had thought that the breaking of the skin weakened a bar of iron; but he understood Mr. Kirkaldy to say that a turned bar would stand as much strain as an unturned one.

Mr. R. B. Bell wished to call to Mr. Macfarlane's attention the fact that Mr. Kirkaldy had drawn up these statistics from actual and accurately-arranged experiments, so that what he had put forward were facts, not mere opinions or prejudices; and he would like to krow if what Mr. Macfarlane stated was merely his opinion, or if he had made actual experiments with bars of equal sizes to ascertain this fact?

Mr. W. Macfarlane said it was from his own practical euperience, but without making any special experiments to test the correctness of his deductions. His belief was that if the skin of an inch-bar of cast-iron were broken, it was weakened very much.

Mr. W. M. Neilson suggested that instead of "practical experience," perhaps Mr. Macfarlane should have said "practical prejudice."

Dr. Macquorn Rankine said he thought that no one would question the greater strength of cast-iron with the skin than without it; but as regarded wrought-iron, he did not believe that there had been any precise experiments until Mr. Kirkaldy made his. There was one matter about which there was no doubt; that if they had to turn a piece of wrought-iron they ought to interrupt, as little as possible, the continuity of the fibres; this was to be insured by forging it as nearly to the required shape as possible, so as to have little cross-cutting of the fibres. He had verified that doctrine at the time when he experimented with the axles, nineteen years ago.

The President said that the skin of all malleable-iron was broken in bringing it into use, as in tyres, axles, &c.

Dr. Macquorn Rankine said that if they took two journals of the same diameter that had been turned alike, but which had been hammered down to different forms, although they were of the same dimensions, yet on account of the continuity of the fibres in the one not being interrupted, it was stronger than the other in which the fibres were cut by the turning process.

Mr. Macfarlane said he hoped they would excuse him pressing upon them the importance of annealing important forgings. His own opinion was that it would materially strengthen them.

Mr. W. M. Neilson remarked that he thought what Mr. Macfarlane insisted on was, in other words, to make the iron more homogeneous.

Dr. Macquorn Rankine said there was one other fact of considerable importance that Mr. Kirkaldy brought out, which had been anticipated by theoretical writers, that the stretching of the metal tended to diminish its density.

Mr. R. B. Bell drew attention to the fact, which Mr. Kirkaldy had made known, that galvanizing did not hurt the strength of iron in large sections; and he could add, that it did not do so in small ones, as had been proved in testing galvanized and ungalvanized wire ropes.

Mr. Macfarlane would like to know what process of galvanizing was referred to, as the one was a mechanical combination with the iron, while the other was chemical.

Mr. Kirkaldy said it was the chemical process.

Mr. W. Simons believed that, with reference to galvanized iron ropes, the result had been quite the opposite of that stated by Mr. Bell.

Dr. Macquorn Rankine said he had made experiments on that subject, and the result he came to was that the ungalvanized iron was, perhaps, a shade stronger, but the galvanized was more extensible. The result was, that what the galvanized rope wanted in tenacity, it more than made up by being more extensible, and it was, therefore, better able to resist a shock. The difference in tenacity, however, was so small, that it might have arisen from errors in the experiments. One peculiarity he had observed in galvanized wire was, that when a certain pull was put upon it, much of the elongation that took place was permanent. Perhaps that arose feom the compression of the layer of zinc. The permanent elongation did not increase by repeated applications of the load, provided the load was within the limits of safety.

Mr. D. More asked if Mr. Macfarlane thought that if they annealed forgings before they were finished it would add to their strength, or must they be annealed after being finished?

Mr. Macfarlane replied that they should be annealed when they came out of the forger's hands, but tempered after they were finished.

Mr. D. More asked—Would there not be some danger of the shaft getting warped?

Dr. Macquorn Rankine asked if Mr. Macfarlane intended them to be put into cold oil?

Mr. Macfarlane answered in the affirmative.

Mr. Faulds said that there would be a danger of twisting a shaft if it were annealed after being finished.

Mr. Macfarlane said that the strength would be increased, but admitted the danger of twisting.

The President then proposed the thanks of the Institution to Mr. Kirkaldy for bringing so valuable a series of experiments before them. He thought they would all agree with him, that the discussion should be adjourned, in order that members who were absent might have an opportunity of giving their views on that important subject, and also in order that they might have an opportunity of inspecting the drawings which Dr. Rankine had so handsomely offered to lay before them.

The vote of thanks was passed, and the discussion adjourned.

STRENGTH OF TIMBER.

The *Scottish Farmer*, in giving the following rule, founded on the experiments of Muschenbroeck, states that specimens experimented upon were in a sound state. Muschenbroeck used the Amsterdam pound, 100 of which is equivalent to 109 avoirdupois:—Locust *(Robinia pseudo Acacia)*, 20,100; beech, oak, 17,300; alder, 13,900; elm, 13,200; mulberry, willow, 12,500; ash, 12,000; plum, 11,800: elder, 10,000; fir, 8,330; walnut, 8,130; pitch pine, 7,650; cypress, 6,000; poplar, 5,500; cedar, 4,880. So much, however, depends on the part of the tree from which the specimen is taken, and also on the nature of the soil, the age of the tree, and other matters, that great variations will be found in different specimens, and one-third of the above breaking weight could only be used in practice, except the line under which the timber has to be stretched is short, when half may be safely trusted to. When the specimen is near the heart or bark it is weakest, and midway between these, strongest; the parts near the root are also stronger than those near the division of the tree into branches; a dry soil produces harder, heavier, finer-grained, and stronger wood than a moist one, and the colour of it is yellower than that of timber grown in a damp soil, arising from its pores being filled with a gummy matter. Sussex, the south-west of Kent, the north-west of Hampshire, produce good oaks, for instance. In seasoning, some will retain the same weight nearly; as common Riga tops, Baltimore pitch pine butts, Halifax and Canada spruce butts, teak tops and butts, Cape yellow wood and stink wood butts, Irish bog oak, Surinam letter wood, and South American cedar. Some will become heavier, from losing more in dimension than weight, as best Riga tops, North American pitch pine tops, and Canada spruce fir tops; most others become lighter. No species hardly ever shortens in seasoning, but they generally do in breadth, from about $\frac{1}{8}$ to $\frac{3}{8}$ of an inch to a foot. Teak, stink wood, Irish bog oak, letter wood, and South American cedar, are exceptions to this. Oak loses one-third of its weight in seasoning, particularly if grown in a moist soil, and the specific gravity varies from 1,090 to 700 in some which he tried. Du Hamel states that the density of trees grown in the same climate, but on different soils, varies from 7 to 5, and the strength, both before and after seasoning, from 4 to 5. When they had not passed their prime, the density of the butt is to that of the top as 4 to 3, and that of the centre to that of the circumference as 7 to 5; the reverse of this occurs when the tree is past its prime. These variations will serve to account for the difference between experimenters. A wood called iron wood, or red wood (supposed to be *Erythroxylon areolatum*), exhibited amongst Jamaica productions at the Paris Exhibition, was found to bear the prodigious weight of nearly 7 tons, the specimen being only 2 in. square and 12 in. long. The strongest wood in the Exhibition of 1862 was in the New South Wales Court, under the name of grey iron bark (*Eucalyptus sp.*), 5 ton 4 cwt. being its breaking weight. Even of that the proper botanic name is uncertain.

THE RICHARDS INDICATOR.

THIS indicator has been aptly termed the "*stethescope*" of the steam-engine. Properly applied, and its deductions rightly followed, it can, no doubt, often cure the iron "*patient*" of *consumption* of fuel. The following is a description, extracted from the specification of an improved form of indicator, invented by C. Richards, of Hartford, Connecticut, and patented in this country by C. T. Porter, 100, Fleet-street:—

The form of steam-engine indicator in most general use is that commonly known as the "McNaught Indicator," in which the piston and its guiding rod have the same range of motion as the pencil, but as the piston and rod are necessarily made quite heavy, and their range of motion extensive, in order to produce delineations on a sufficiently large scale, the momentum of these parts is so great, and tremulousness of the spring is so considerable, as to render the instrument unserviceable for application to engines having rapid movements. While, therefore, it is desirable to reduce the momentum of the parts which are moved by the varying pressures of the steam, as well as the length and consequent tremulousness of the spring, it is also desirable that the pencil or marking point should move in a straight line, in order that its delineations, which should be on a large scale, may readily be measured with accuracy, and in order also that the paper on which the delineations are made may be clamped in the usual manner around a cylindrical drum, to which the requisite movements can be readily given by the customary means. To furnish an instrument possessing the above-mentioned desirable features is the object of this invention, and to this end it consists in the employment of a lever, or its equivalent, so connected with the pencil and the piston as to give to the pencil a range of motion greater than that of the piston in combination with a system of levers or an equivalent therefore, so arranged as to cause the pencil's point to travel in a straight line, substantially in the manner hereinafter clearly set forth.

Figure 2 is a plan of the same. Figure 1 is a side elevation of the instrument. Similar letters of reference denote the same parts in the two figures.

In the accompanying engravings A is a cylindrical case containing a small steam cylinder B, in which moves a piston, the movements of which are regulated by a spiral spring inside. These parts are constructed and arranged in a manner similar to, but are much shorter than the corresponding parts of, an ordinary McNaught indicator, making delineations on the the same scale. To the outside of the case A is secured a ferule E, an arm from which supports a cylindrical paper holder F, which in construction and arrangement is similar to the paper-holding drum of a McNaught indicator, and it receives the proper reciprocating movements in the same manner. Around the upper part of the case A is a ferule G, to which are attached two arms H and J, one of which, J, supports the fulcrum pin K of a light lever L, the extreme end of which lever is jointed to the end of a lever or link M, the opposite end of which is jointed to the extremity of a delicate lever or radius bar N, the fulcrum pin O of which is suported by the arm H. To the lever L, at a point distant from its fulcrum K, about one-fourth of the length of the lever, the rod P of the piston C is connected by means of a forked link Q, which is jointed a knuckle R to the upper end of the rod P. In the centre of the link M is a holder for the pencil S, which receives from the piston C, through the lever L, a range of perpendicular motion about four times greater than that of the said piston, and the levers L and N are so proportioned, and their fulcrums are so adjusted, that the marking point of the pencil S is caused to move in a straight line in the same manner that the "parallel motion" of a steam engine causes the end of the piston rod to move in a straight line. The movements of the lever are indicated in Figure 1. The application and mode of using this improved indicator are essentially the same as of McNaught's instrument, and need no description.

THE RICHARDS INDICATOR.

CAPTAIN BOLTON'S IMPROVEMENTS IN TELEGRAPHING FOR NAVAL AND MILITARY PURPOSES.

LAST week the *Times*, in its "Naval and Military Intelligence," gave an animated description of experiments recently made at Portsmouth to test Captain Bolton's system of telegraphing for naval, military, and other purposes. It is said the experiments were quite successful. Underneath will be found a detailed description of the invention, which relates to a means of transmitting intelligence or despatches in broad daylight by means of signals produced by flashes of light of long or short duration, or both combined. This object is effected by the employment of an intensely powerful light, consisting either of the electric light, the lime, or other light, which is to be alternately obscured or eclipsed and displayed so as to produce visible flashes of light of long or short duration, and in any desired order of succession so as to produce the required signals. In combination with this light, lenses, reflectors, or other well-known optical arrangements, are used, in order to prevent the dispersion of the light, and to more effectually concentrate or project it in the form of a pencil of rays upon the distant station or observer. The signals are produced by temporarily obscuring the light by means of shutters (or other suitable contrivances) for longer or shorter periods, and in any pre-arranged order that may be desired. In conjunction with this apparatus for transmitting the light, the signals are received in a darkened chamber, or other convenient appliance, through a lens or on a reflector, whereby they are concentrated on a field, from which all unnecessary rays of light are excluded. By these means the eye of the observer, being relieved from the redundant or extraneous light, will be enabled more readily to perceive and note the signals that are made at the distant stations. The light whereby the signals are produced may be obscured or displayed; that is, the shutters or equivalent contrivance may be raised and lowered, by causing electro-magnets to act on armatures connected with the shutters. These electro-magnets may be put in action from a distant station, by causing a current of electricity to pass through the coils of the electro-magnets in any of the well known manners for working electro-magnetic apparatus.

Fig. 1 is a plan of the apparatus with the cover removed, and Fig. 2 a section of the same. A is the oxyhydrogen gas jet, which is supplied with the two gases through pipes or tubes; B is the

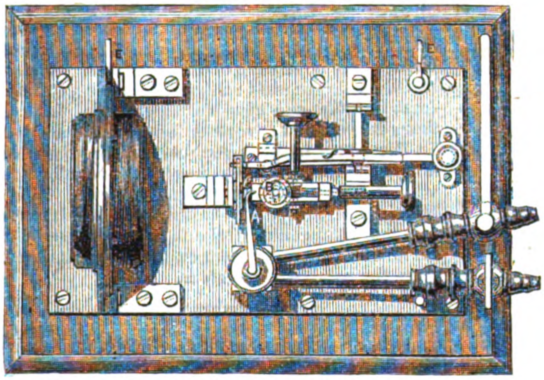

FIG. 4.

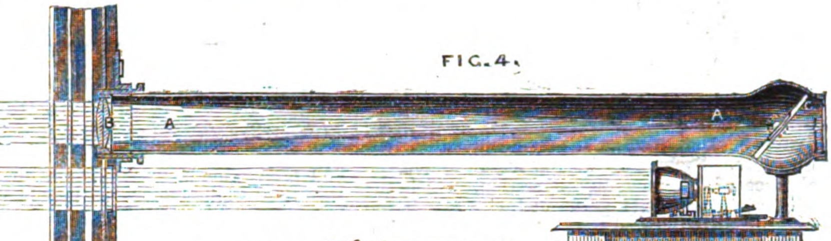

FIG. 3.

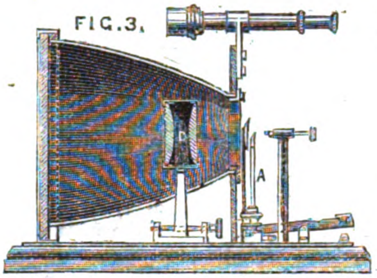

FIG. 6.

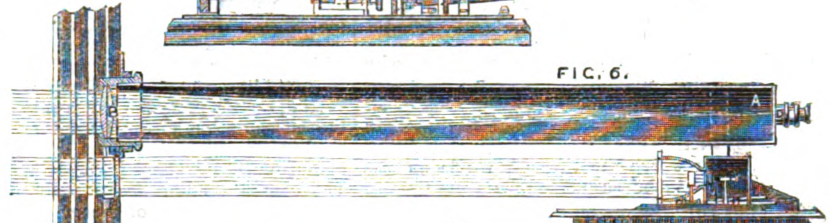

FIG. 5.

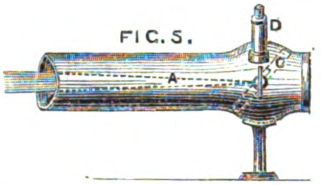

lime cylinder mounted on the vertical stud pin, which may be caused to revolve by means of a worm, which is worked by hand, or by means of clockwork if desired. The vertical stud pin is held in a spring clamp, fitted with a screw adjustment, by which the distance of the lime from the gas jet can be regulated and adjusted at pleasure with nicety. The lime cylinder may be placed horizontally instead of vertically, as shown at Fig. 3.

The shutter consists of a circular piece of platinum or other metal slightly concave, attached to a cranked arm, which is mounted upon a stud axle, carried by a bracket screwed to the bed plate of the apparatus, and immediately behind the gas jet. The lower end of this lever arm has a projection at right angles to the arm, in which is a horizontal slot. In this slot works one end of a key lever, which turns upon a fulcrum pin carried in brackets screwed to the bed plate. The opposite end of this lever carries a finger button, by which the operator depresses the lever, and immediately the arm carrying the shutter will be removed from before the light. A spring is caused to bear up against the under side of the lever, and returns it to its former position, when the pressure of the finger of the operator is removed. By thus depressing the lever, for a longer or shorter time, the rays of light will be thrown in flashes of longer or shorter duration on to, and through the arrangement of lenses, shown in section at Fig. 2, which is simply a combination of two plano-convex lenses mounted in the vertical plate, and capable of adjustment laterally. It will, therefore, be obvious, that any other arrangement of lenses may be used that will effectually concentrate and project the rays of light in parallel lines. In order to adjust the position of the instrument, so that the signals shall be projected on the distant station, two telescopic lenses, or eye-pieces E are attached to one side of the instrument, or a telescope may be mounted thereon.

A modification of the above described apparatus is shown at Fig. 3, which is a longitudinal vertical section of an apparatus in which the lenses D are surrounded by or placed within a parabolic reflector, for more effectually preventing the dispersion of the rays of light, and for concentrating the rays on the centre of the lenses. The circular platinum shutter may be divided into two parts, and slightly overlap at the joint. Each part can be rivetted on vertical arms screwed to the bed plate of the apparatus. Any number of lime lights and lenses, combined and arranged around a common centre, may be used.

Fig. 4 shows a sectional view of an arrangement of apparatus for receiving the signals from distant stations. Fig. 5 is a detached side elevation of part of the apparatus. The rays of light from the distant apparatus are received in a darkened chamber or tube A, through the lens B, adapted to the outer end of the tube A, and by which lens the rays are condensed and thrown upon a field C. This field may be made of a flat disc, painted black, but having a white spot or centre, and can be set at the proper angle by adjusting screws. An eye piece or magnifier D is mounted on the end of the darkened chamber or tube, as seen in Fig 5, for the purpose of minutely examining the disc. The tube or darkened chamber A is supported on a table, or in any other convenient manner, so that by means of the magnifier or eye-piece D, the most delicate pencil of rays will be rendered visible, and may be easily read off by the observer.

An instrument for the transmission of signals in answer, similar in construction to that just described, is represented at Fig. 6. It will be seen that the rays of light are received in a darkened chamber A; but, instead of being thrown on to a disc C, they are conducted direct to the eye-piece D. This is, perhaps, a more convenient form of apparatus, but if desired, a reflector may be substituted for the disc C, and the signals may be read off without the aid of a microscope. The signalling or telegraphing apparatus above described may either be placed at fixed points, or it may be made portable for military purposes. It may also be used on board ship for signalling or communicating intelligence to stations on shore or with the several ships of a fleet or squadron; and as every facility exists for making long or short flashes of light, signals or intelligence can be communicated with great rapidity by means of such long or short flashes, or both combined, according to any pre-arranged code of signals.

EXPERIMENTS AT SHOEBURYNESS.

On Tuesday last, some target trials took place at Shoeburyness. The iron shield of Capt. Inglis, R.E., which was tried on that day, was intended to test the value of thick iron plates as embrasures for casemated batteries of masonry. The shield is 11 ft. in length by 8 ft. in height, with an embrasure in the centre. It is composed of slates of iron of different thicknesses, varying from 4 to 8 in., the thickest plates being next the embrasure, the armour plates and backing, which is composed of thinner plates, being a body of about 15 in. of iron, which, with the diagonal supporting frame, cannot equal less than 18 in. of solid iron, or 720 lb. per foot area. The fastenings are chiefly through bolts, with elastic washers. Whatever may be the objections to such fastenings for lighter armour plates, they certainly stood the test well on Tuesday, while the rivet heads, which at previous experiments have stood best, were inferior in this instance. The guns used were the regular service 68-pounder, a 110-pounder Armstrong, and a 120-pounder Whitworth. The destructive effect of the old smooth-bore was greater than that of either of the rifled guns. Indeed, as far as a test of ordnance is concerned, the experiments of Tuesday possess no great value. The Horsfall monster gun and the 150-pounder Armstrong (erroneously called a 300-pounder) were wanting to thoroughly test a target of such weight and thickness. The indentations produced by the sixty-eight were about an inch and a half in depth, those by the rifled projectiles falling short of this. It is said that the success of the experiments was due in a great measure to the excellent quality of the iron plates, which are hammered plates, manufactured at Millwall Ironworks. The only interesting question which these experiments has decided is one that has lately been the subject of much conjecture with many, viz., What would become of the Whitworth flat-headed homogeneous iron or steel projectile when it met sufficient strength to resist penetration? That question is now decided. It goes to pieces. Some surprise was manifested at the absence of the punching operation, which the Whitworth projectile performed with ease in the case of 4½ or 5 in. plates. But all mechanical experience proves that the diameter of the punch must equal, if not exceed, the thickness of the plate, and therefore it is simply impossible that a projectile 7 in. in diameter could punch a hole in a plate 7¾ in. in thickness. The fact that the rifled projectiles destroyed themselves so completely partly explains why, with a charge of 50 per cent. more powder, they did less damage than the round shot of the old smooth bore.

SINKING OF A RAILWAY VIADUCT AT CLAPHAM.

On Wednesday morning an occurrence of a serious nature, though fortunately unattended with any loss of life or bodily injury, took place near the Clapham station of the Metropolitan Extension of the London, Chatham, and Dover Railway, by which the through traffic on the line will have to be suspended for some time to come. It will doubtless be remembered that that part of the Metropolitan Extension Railway, which is to join the Victoria Station at Pimlico by a bridge across the Thames at Blackfriars with the Farringdon-street terminus, was opened a short time back from Victoria to the Elephant and Castle. The second station on the line is that at Clapham, and at about 200 yards distant the line crosses the Clapham-road and the Bedford-road by means of iron-girder bridges. Between these two bridges is a viaduct, consisting of nine arches of massive brickwork, standing in a field. All the structure appeared to be quite safe up to the evening of Tuesday, when there were slight indications in the parapet of a subsidence of one of the centre piers taking place. The officials of the company were at once apprised of the fact, and every precaution was taken for the safety of the public by watching, &c. On Wednesday morning, at about half-past six o'clock, the men on watch found that the pier began to sink rapidly, and before long it had subsided upwards of four feet into the earth, carrying with it the next pier, and, as a matter of course, the centre arch and portions of the arches on each side. Notwithstanding this great sinking, and the manner in which a large portion of the brickwork had become broken up, the rails did not give way for some time. Information was at once sent up to the Victoria terminus, as a train was to leave at 7.25, and the working beyond Clapham was stopped. Almost immediately a large body of workmen were on the spot, and the traffic between the Clapham and Brixton stations having been suspended, steps were taken to shore up the arches on both sides of those damaged.

At an early hour the chief engineer of the line, Mr. George Cubitt, with Mr. Turner and Mr. Thomas, of the engineering staff, and other gentleman, visited the spot, and examined the sunken piers and damaged arches, and, from their inspection, there is no doubt that the whole must have given bodily, as there was not the slightest appearance of defect in the brickwork, which is of the best description. It seems certain that the pier on the Clapham-road side must have gone first, carrying the other portion with it. As to the cause of the subsiding of the pier, no positive reason can be assigned. The foundations were laid on the solid gravel, and as there is no knowledge of the existence of any old sewer in the vicinity, the conclusion arrived at is, that there is a peat bottom at some considerable depth below the gravel on which the foundations rested. However, men were employed all day in taking down the damaged arches, and when the brickwork is removed, the foundations will be dug out, and the exact cause will, no doubt, become apparent.

MANUFACTURE OF WROUGHT-IRON DIRECT FROM THE ORE.

(From Truran's "Iron Manufacture of Great Britain.")

The production of wrought-iron direct from the ore—the original mode of manufacturing—has engaged the attention of numerous practical and scientific men, and is practised to a limited extent abroad; but the attempts made to reinstate it in this country, have hitherto been, commercially speaking, unsuccessful; and though the ores and fuels we possess are unquestionably superior to the foreign for this purpose, fusion in the blast furnace, and conversion into malleable iron by the puddling process, is pursued with all the bar iron now manufactured.

The conversion direct into malleable iron dispenses with the blast furnace and appendages, and the intermediate processes of refining and puddling, and if successful, should result in the production of a finished bar of superior quality, with a smaller consumption of ore at a proportionately lower cost. In all experiments on converting on this plan, the bar is of inferior quality, the consumption of ore larger, and the cost of production augmented over that attending the manufacture by blast furnaces and refineries. The causes tending to produce this difference between the results of theory and practice are numerous, but will receive from us only a brief notice.

The ore to be converted is ground to a coarse powder, and in mixture with a quantity of carbonaceous matter similarly divided, is charged into a reverberatory furnace not unlike the ordinary puddling furnace. The draught is forced to the production of a high temperature, reducing the ore to a semi-liquid state, when by dexterous manipulation on the part of the operative, metallic iron is separated from the extraneous matter, balled up, and shingled as in the usual manner. The theory of this operation is simple. The carbon of the carbonaceous matter is consumed by uniting with the oxygen of the ore, and the metal is left free to agglutinate into a mass. The Beaufort black band was thus converted into malleable iron, though after a few experimental trials the operation was discontinued. The principal objection to its extensive adoption, seems to lie in the difficulty of effecting a complete separation of the extraneous metalloids of the ore. In the blast furnace it is accomplished by mechanical subsidation in the hearth, and the extraction of the metallic iron from the low level; in the direct mode of manufacturing it is effected to a certain degree, by severe manual labour, which being skilled, commands a comparatively high price, and materially enhances the expenses incident to the process.

The prolonged exposure of the metallic iron to the oxydizing influence of the flame and gases during the process of separation from the alloyed matters, results in a considerable waste of metal, and accounts for the comparatively inferior yields.

To obviate this loss, and to economize the fuel, and labour demanded, the ground ore and carbonaceous matter have been subjected to the necessary heat in a closed supplementary chamber, whereby the combustion of the carbon is slowly carried on at the expense of the oxygen of the ore, but at a sufficiently low temperature to avoid oxydizing the mass. From this chamber it is drawn as required into the furnace, balled up and shingled, the deoxydized ore agglutinating without undergoing the puddling process, which being essentially a decarburizing process is unnecessary with the minimum volume of carbon consumed in the deoxydation of the ore in the close chamber.

Ground carbonaceous ore may be substituted for the carbonaceous matter, and mixed in the necessary proportions with the same ore calcined, or, with raw hermanite, the deoxydation can be effected without the usual ground coal, at a corresponding reduction in the expense. In this respect, the possession of ores of such varied character, gives the ironmasters of this country an important advantage over their foreign compeers; and, should this mode of manufacture, at some future day, become more profitable than at present, would enable them to maintain their supremacy in the trade. The rich carbonaceous ores of Scotland or Wales, mixed with the hematites of Lancashire or West Cumberland, or other similar ores, reduced in suitably constructed furnaces, may be converted into malleable iron, at costs considerably under those incurred with the blast furnaces and subsequent decarburizing system.

With existing modes of operation, the advantages of direct conversion are principally confined to the comparatively small capital required to establish the manufacture, which may be on the smallest scale, yet, to a corresponding extent, profitable. Hence it is especially applicable to new districts, requiring an immediate small supply, and to countries deficient in the capital necessary for carrying on operations on a large scale with blast furnaces, and attendant refining and puddling furnaces. To establish on a sound basis works consisting of blast furnaces, refineries, puddling forges, and rolling mills, a capital of at least £20,000 per blast furnace, where there are four, is required; with a fewer number, more. In the direct mode wrought iron in proportionately smaller quantity may be manufactured, with a capital of only one-twentieth, or one-thirtieth of this sum. In this respect, therefore, it is more advantageous, and may consequently, under certain circumstances, merit the preference over the established system.

Legal Intelligence.

COURT OF BANKRUPTCY.—Dec. 29.

(Before Mr. Commissioner Golburn).

Re Bastier.—This was the adjourned sitting for examination and discharge. The bankrupt was described as an engineer, of Manchester-buildings, Westminster. Mr. Sargood opposed for the directors of the Graving Dock Company, of Liverpool. The bankrupt was the patentee of a chain pump, and he had employed the opposing creditors to construct several pumps on his patent, one of which had been exhibited in the Exhibition. He had paid nothing, and the pumps were gone.—The bankrupt, in a letter which he had written to the Court in very amusing English, alleged that he had spent £4,000 in this country.—His Honour adjourned the examination *sine die*.

SMOKE CONSUMING APPARATUS.

On Tuesday last Mr. Charles Young, solicitor, accompanied by Mr. William Sandison, the engineer appointed by Government to carry out the provisions of the Smoke Nuisance Act, came before Mr. Woolrych, at the Thames Police Court, and reminded him that on the 15th of November last Mr. John Fairrie, the extensive sugar-refiner, of the Commercial-road East, in the hamlet of Mile-end Old-town, was fined £5 for unlawfully using a certain furnace not constructed so as to consume its own smoke. At the same time it was arranged that the fine should not be enforced for six weeks, if the defendant used the best practicable means to comply with the requirements of the law. Mr. Sandison believed that Mr. Fairrie had used every possible effort to obtain a proper apparatus, and, after spending a considerable sum of money, had failed. Mr. Fairrie had given orders for another apparatus, and he now asked for another adjournment, to enable Mr. Fairrie to complete the necessary alterations and improvements.

Mr. Charles Young said that Mr. Fairrie had expended £75 since the 15th of November in applying a smoke-consuming apparatus to one furnace. It was a failure, and he had to begin again. Mr. Fairrie intended to spend £700 in applying an apparatus for the consumption of smoke to each of his seven furnaces.

Mr. Woolrych: Will a smoke-consuming apparatus for each furnace cost £100?

Mr. Charles Young: Yes, it will indeed, sir.

Mr. Woolrych was glad, for the sake of the public, that there was a prospect of a speedy discontinuance of the dense volumes of black smoke from the chimney-shaft of Mr. Farrie's extensive sugar refinery.

Mr. Charles Young: The works will be proceeded with as rapidly as circumstances will permit.

Mr. Sandison asked for the costs. The charge for two inspections of the furnaces is £2 2s.

Mr. Charles Young: My client will pay the £2 2s.

Mr. Woolrych: Very well. The penalty will not be enforced at present. The case is adjourned for six weeks.

Meetings for the Week.

Mon.—*London Inst.*, "On Sculpture," by R. Westmacott, Esq., R.A., at 7 p.m.
Tues.—*Royal Inst.*, "On Air and Water" (juvenile lecture), by Professor Frankland, at 3 p.m.
Wed.—*London Inst.*, "On the Operation of Heat," by E. W, Brayley, Esq., at 7 p.m.
Geological Soc., Special General Meeting.
Thur.—*Royal Soc.*, at 8.30 p.m.
Civil and Mechanical Engineers' Soc., "On Warren's Triangular Girders," by J. B. Walton, Esq., at 7.30 p.m.
Royal Inst., "On Air and Water" (juvenile (lecture), by Professor Frankland, at 3 p.m.
Fri. — *London Inst.*, "On the Chemistry of the Non-Metalic Elements," by F. Field, Esq., at 7 p.m.
Architectural Assoc., "Architectual Criticism," by L. W. Ridge, at 8 p.m.

The Ottoman National Exhibition.—Notwithstanding the severe weather which has prevailed during the greater part of the past week, the building in the Hippodrome has been actively proceeded with by crowds of workmen. By the end of the month the entire shell of the structure will, it is expected, be complete and ready to receive the roof, which it has now been decided shall be of glass. Azim Bey has been named Imperial Commissioner—whatever that may mean—for the enterprise, and is already at work with Mustapha Pasha on the details of the allotment of space, the classification of the expected contents, and other executive duties of the undertaking. The week's news from the provinces reports favourably for the progress of preparations among intending exhibitors. From Bagdad the telegraph states the goods to be ready for transmission. Similar intelligence comes from Aleppo, Adrianople, and Upper Albania, from the last of which an extensive display of native arms is promised. These will be arranged as a trophy near the entrance of the building, as *vis-a-vis* to another to be formed of cannon and small arms manufactured at Zeitoun-Burnou. Splendid specimens of embroidery are promised from some of the chief harems of the capital, where the fair candidates for medals and "honourable mention" are now busy with this object. A special day in the week, by the way, is to be set apart for the admission of ladies to the building, on which the unfair sex will be rigorously excluded—as will be the houris themselves on the other six. As intending English exhibitors have yet ample time to obtain the requisite space for their goods, it may be worth while to express our conviction that agricultural implement makers will especially find the experiment a paying one, as their articles, above all others, are sure to find ready and liberal purchasers at the close of the exhibition.—*Levant Herald.*

Scottish Institute of Civil Engineers.—On the 24th ult., the usual monthly meeting of this Institute was held in the Philosophical Society's Hall, George-street; Professor Macquorn Rankine, in the absence of the President, in the chair. Five new members and one graduate were unanimously elected; after which the Institute agreed to remit to their council to appoint a committee to assist in making arrangements with the Philosophical Society of Glasgow for a *conversazione* in the end of January. The adjourned discussion on "Experiments on Wrought-Iron and Steel," by Mr. D. Kirkaldy, was then resumed and finished. A paper was then read, "On obtaining Fresh Water by Evaporation," by Mr. George Russell, a new apparatus being shown in explanation of the paper. Mr. John Warner, of Pennsylvania, described an instrument for aiding in the computation of earthwork.

Correspondence.

◆

THE TENSILE STRENGTH OF IRON AND STEEL.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In your last issue I have perused with great interest a paper read by Mr. David Kirkaldy, detailing the results of an experimental enquiry into the comparative *tensile strength* of iron and steel. My attention has been arrested by two statements: the first is par. 35—that steel is reduced in strength by being hardened in water, and that its strength is vastly increased by its being hardened in oil. This appears to me, though partly correct in fact, yet altogether erroneously expressed. I am aware that gunsmiths, and other fine workers in iron, use oil instead of water in tempering steel, and I have done so myself repeatedly in India, where a person is often obliged to do much for oneself that in England can be better done for you; but I always considered that the advantage was chiefly owing to the lower temperature of the oil kept in the house, and to the less immediate transmission of heat through the oil as compared with water, thereby causing the process of cooling or tempering the steel to be *less sudden*. There is, besides this, another advantage arising from this use of oil, namely, that it leaves on the tempered surface a film of protective varnish which in India, where iron and steel so quickly oxidise, is of no small profit.

But, if I am correct in supposing these to be the sole advantages arising from the use of oil instead of water, then assuredly it is a mistake, in a practical paper like this, to ascribe to oil, as oil, the virtue of toughening steel by its being dipped therein at a certain temperature.

It would lead unscientific men to conclude that the oil permeated the interior structure of the heated metal, and being absorbed by it, cooled it and toughened it; whereas, all men who really know anything about the structure of metals, and the nature of oil and water, know this to be simply impossible.

The *direct* action of the water and oil is solely on the surface of the metal; but if that surface be less suddenly cooled in oil than in water, there is, besides, an indirect action on the interior of the mass, inasmuch as heat is abstracted from it also less suddenly, and it becomes, therefore, when tempered, less hard, less brittle, and more tough.

The higher you raise the temperature of the steel which is to be tempered, and the colder the fluid into which you plunge it, the harder and more brittle it becomes. Thus, in India, glaziers never use a diamond to cut glass, but they do all their work with a steel point, hardened as I have above described. I have hardened steel myself so that it was as brittle as glass itself, by plunging it at nearly a white heat into iced water.

But once it is admitted that the *direct* action of the fluid is only on the surface of the metal, it follows that the description given conveys an erroneous impression, likely to mislead, to induce misconception and error; in short, to do more harm than good; because the result does not arise from the lubricating qualities of the oil, but rather from its being at a lower temperature, or from its absorbing heat less readily than water; for we might easily substitute some aqueous compound that would answer the same purpose—say, earth and water, or flour or glue and water, or any such mixture of greater or less density and specific gravity than water. Glue in particular appears to me likely to have the most admirable effect, seeing that case hardening is still effected by surrounding iron with scraps of leather and other animal substances, and subjecting the whole to prolonged heat.

The second statement which I advert to is, that it was (par. 62) previously believed that the density of iron was increased by wire drawing, whereas it is now ascertained to be decreased by cold rolling as well as drawing.

Certainly, *I* never imagined that stretching iron could increase its density. Take, for instance, a piece of dough; if you pull it out you increase its size, but you decrease its density and specific gravity.

Thus, also, a piece of lead: strike it a sharp blow with a large hammer, you make a circular dent or depression on its surface; you have increased its density, and if you could attach two suckers to the depressed surface, so firmly that they should not be detached when sufficient exterior strain may be exerted to pull out the lead to its original dimensions, it is very evident that you would thereby decrease the density of the compressed lead, and bring it back to its original state. And even thus is the drawing of iron or steel wire: you pull it out by means of powerful leverage, and distend it so that it occupies greater space than it did before; it consequently, and necessarily, weighs less in comparison to its bulk.

So much for the consequences of wire drawing metal; but, as regards cold rolling, I feel inclined, like the sages of old, to question the fact alleged by the king, that you might fill a bowl of water *quite full*, and yet that the addition of fish thereunto would not cause it to overflow. I have never tested rolling operations, and must therefore write with reserve and diffidence; but it is my firm impression, that a first process of cold rolling steel or iron would increase, and not decrease, its density. I mean, that if an iron bar were passed cold through steel rollers, set so far apart that they would exert such pressure only as would very slightly decrease its thickness, I believe that the density of the iron bar would be found to be increased and not decreased. I would, of course, not deny that were thin iron wire to be formed by passing it through a gradation of steel rollers, instead of the usual process of drawing, it might suffer a decrease of density; but I maintain that if a drawn wire were to be subjected to a slight pressure through rollers, its density would be thereby increased, and not decreased; and it appears to me that an interesting experiment might be made as to whether steel wire, as required for the use of pianoforte makers, might not be strengthened and improved in tone, either by being made solely by cold rolling, or by being subjected to rollers, as above described, subsequent to being drawn out. Certainly, if not for England, it seems to me that wire for pianofortes sent out to India and other hot and dry climates, where pianoforte wires not unfrequently snap, would be an advantage and improvement.

I am, &c., Chas. Bathoe.
28, York-place, Portman-square.
Dec. 27th, 1862.

Sir,—In perusing the valuable paper in your last issue, detailing the conclusions arrived at by Mr. Kirkaldy regarding the tensile strength of iron and steel, a few questions suggest themselves.

Does not section 23 somewhat contradict section 8? for this "skin" (admitted by Mr. Kirkaldy to be harder than the inner part), being removed by turning, must surely leave the bar less strong than before?

How are we to understand section 18?—"Iron invariably presents a crystalline appearance when fractured suddenly, but a fibrous when fractured slowly." Does he mean to say, that the interior of a bar of iron, when entire, is in neither of these states, but is *turned into* one or the other, according to the method of breakage? Are we to understand that the appearance of the fractured section is no guide to the internal structure of the remainder of the mass? For instance, that having a homogenous bar 2 ft. long, we may, 6 in. from one end, fracturing it suddenly, find it crystalline, and 6 in. from the other, fracturing it gradually, find it fibrous? If so, how close may the two fractures be brought, without interfering with this phenomenon?

And in section 48 we read, "the amount borne was much less when the diameter was uniform for some inches of the length than when confined to a small portion."

Does this mean, that if we had a bar 10 ft. long, of which 6 ft. were 2 in. in diameter, and the remainder only 1 in., that we should *increase* the breaking strain by reducing 9½ ft. length to the smaller amount, and leaving only ½ ft. in length, 2 in. in diameter?

I do not pretend to say these things cannot be correct, but they sound rather strange to
Your obedient servant,
Dec. 27th, 1862. Ignoramus.

SILICA OF POTASH.

Sir,—Will you have the kindness to allow me, through the medium of your valuable paper, to ask some of your numerous correspondents how to make silica of potash, so as to become soluble in boiling water. I have just past through some experiments, with a view of obtaining a silica of potash, soluble in boiling water, but failed to obtain such a result. My mode of proceedure was as follows:—I took 15 parts of quartz sand, 10 parts of carbonate of potash, and 4 parts of charcoal, in powder, mixed them, placed them in a crucible, and subjected them to a strong heat in a brass caster's furnace, until it was melted so as to run from the crucible, while in the melted state, like treacle; when cold it had the appearance of a black slag, very hard; when pounded and ground to a fine powder, its colour was grey. I then boiled it for five hours, constantly stirring it, and keeping it up to a boiling point. If some kind correspondent can give me the *right* mixture and process, or will point out the cause of the failure of the above method, I should esteem it a great favour.

I am, &c.,

Dec. 29th, 1862. J. B. B.

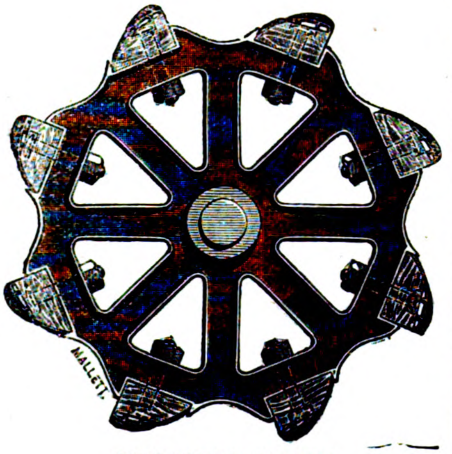
GOUCHER'S BEATER FOR THRASHING MACHINES.

SIR,—I should be obliged by the insertion of the enclosed drawing and description of my patent beater drum for machines for thrashing corn and other grain, at an early period in your excellent Magazine.

Previously to the application of steam power to work the thrashing machine, the drum beater was so imperfectly constructed, even at the low velocity at which it was driven, as to crush the grain and break the straw in a very prejudicial manner; and to avoid those serious results, and to adapt the drum to be driven at an increased velocity, I devised and patented the beater with grooves in its surfaces, and its improved construction patented in 1860.

The peculiar construction of the improved beaters consists in the working sides of the grooves being vertical, and the other sides inclined and rounded, which, being thus formed, permanently retain their keen thrashing surfaces, and secure the two very important advantages over all other beater drums in the operation of thrashing, namely, every corn is thrashed out of the ear uninjured, leaving the straw straight and unbroken. Upwards of 4,000 of these drums are in use in the United Kingdom, on the Continent of Europe, and in Australia.

FIG. 4.



CROSS SECTION OF DRUM.

Figs. 1 and 2 show a longitudinal section and plans of a portion of a beater, *a a* being the working surface, and *b* the under surface. Fig. 3 is a transverse section of beater plate, showing the method of securing it to the wooden bar. Fig. 4 is an end view of the beater drum, showing the method of securing the wooden bar to the drum ends. The beater plates and drum ends are composed of malleable cast iron.

I am, &c.,
JOHN GOUCHER.
Church Walk Ironworks, Worksop, Notts.
Dec. 22, 1862.

GOUCHER'S BEATER FOR THRASHING MACHINE.

LONGITUDINAL SECTION.

FIG. 1.

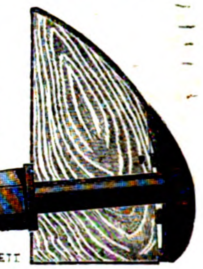
PLAN OF BEATER.

FIG. 3.



SECTION.

For the past three or four years, says the *Morning Herald*, Lord Clarence Paget and the Duke of Somerset have been spending the modest sum of £250,000 a week, £1,000,000 a month, and £12,000,000 a year, and still the very things which should have been done with the money remain undone. The consequence is, the Admiraly is, at the moment, in a mess.

Gossip.

The French Mint is preparing some new copper money, on which the Emperor is represented surrounded by laurels. It is said that this design will be adopted on all the French coins, and on the postage stamps also.

About a fortnight since the gunboats "Cairo," "Marmora," and "Signal" ascending the Yazoo River, reached a point a mile below Hayne's Bluff, U.S., when a torpedo exploded under the "Cairo," shattering her bow. She sank in fifteen minuites, in forty feet of water, and cannot be raised. No lives were lost. The "Cairo" was one of the first iron-clad gun boats built for service on the western rivers, and participated in the capture of Forts Henry and Donelson.

Messrs. Spill and Co., of Hackney-wick, have, after many strenuous exertions, managed to make excellent india rubber driving bands. These bands, have, we are informed, been subjected to severe official tests with complete success.

Amongst the preparations Mr. Fechter is making for the opening ofthe Lyceum Theatre on the 10th, is one consisting in the new arrangements for lighting. The chandeliers round the boxes will be removed, and the theatre will be lighted by Messrs. J. Defries and Sons "Patent Sunlights."

On Tuesday last Colonel Yolland, R.E., the Government Inspector of Railways, made another trip along the Metropolitan Railway line. Messrs. Tanner, Fenton, Johnson, and other officials were present. The train, consisting of an engine and carriage, started from Paddington about 11-50, a.m., along the up-line to Farringdon-street station. After a careful examination of the altered signals and the electrical indicators which have been furnished for the purpose of showing the position of the distant semaphores, the train returned along the down-line of rails to Paddington. The result of this further investigation is the entire removal of all opposition, on the part of the Board of Trade, to the immediate opening of the line. This is, howerer, again postponed till Saturday, the 10th of January, while the inauguration banquet is expected to come off the 7th instant. The banquet room is being gorgeously decorated for the occasion.

The Russian Government has commenced the development of an iron navy. Messrs. C. Mitchell and Co., the extensive shipbuilders, of Newcastle-on-Tyne, have been intrusted with all the arrangements necessary to convert the Government dock yard at St. Petersburg into an iron ship building yard. Steam engines, punching, shearing, and other machines of the most modern construction, have been sent out from Manchester and London. A railway will traverse the dockyard and communicate with the workshops and building slips. Steam travelling cranes will be erected over the vessels while in course of construction, thus performing the greatest amount of work by means of mechanical appliances.

Advices received from Philadephia state that the fibre of the plant Hibiscos Moscheutos is occupying the attention of the merchants at that port as a substitute for linen rags and jute. This plant is indigenous to the Northern States, and grows in abundance in the swampy lands of Pennsylvania, New Jersey, New York, &c. At a moderate calculation, and taking into account the probability of loss from unforesen causes, three and a half tons of disintegrated fibre can be derived from one acre of ground. Two prominent paper manufacturers of New York have estimated the fibre to be worth 100 dols. per ton, to be used as a substitute for linen rags in the manufacture of paper.

A letter has been published stating that Mr. Bright's firm, at Rochdale, is losing from £7,000 to £8,000 per annum, by running its mills, independently of what they are giving away, which can never be known.

The French treaty is benefiting France and England more than Mr. Cobden, or the French Emperor anticipated. There were imported from this country to France 18,500,000f. worth of machinery in 1861, and 25,800,000f. worth in 1862.

The committee appointed to test the merits of the Armstrong and Whitworth guns will consist of the following officers:—Major-General Rumley, Inspector-General of Infantry, president; Colonel Taylor, R.A., Commandant of the School of Gunnery; Major Young, R.A., Director of Artillery Studies; Colonel Simmons, C.B., R.E.; Captain Preedy, C.B., R.N.; and Commander Sluger, R.N.; with Captain Dyer, R.A., secretary. It is to be observed that the members have not previously served on similar inquiries, and are free from official bias as regards the merits of either invention.

The precise sites of the proposed new metropolitan bridges across the Thames are defined by the plans and sections just deposited with both Houses of Parliament and clerks of the peace. They are five in number—namely, the Tower-bridge, St. Paul's-bridge, the Temple-bridge, New Chelsea and Battersea-bridge, and Wandsworth-bridge; the first three for foot passengers only, and the other two for both carriages and horses. The time specified for the completion of the bridges is six years, and the toll to be taken is one half-penny.

The Mormons are turning their attention to the cultivation of cotton.

The New York papers boast of an invention which will destroy iron-clads, the most impregnable of them being as unprotected against it as a wooden vessel against a 500 lb. ball. The inventor is an engineer in the pay of the Government—has been in the Naval Engineer corps for years, and while attached to the man-of-war, "Kearsarge," in the Mediterranean, conceived the idea which is to revolutionize even the latest modes of naval warfare. The gentleman alluded to was recalled from the Mediterranean, and arrived some weeks ago. He visited the Navy Department, and laid before a somewhat incredulous board the nature of his extraordinary plan. His scheme is to get a fair and impartial trial, and an iron-clad man-of-war, now in course of construction, has been turned over to him that he may have his machine fixed to his satisfaction.

At a meeting of the Liverpool School of Science, for the distribution of prizes, on Friday last, Dr. Fairbairn alluded to our transition state with regard to shipbuilding, and ordnance generally; observing that our naval architects had now to contend against shot of 300 lbs. weight striking a ship with a velocity of 15,000 ft. per second; and as this weight, multiplied into the square of the velocity, gave the amount of the shock sustained by the ship, it was easy to conceive the amount of the injury which was produced by ordnance of the large calibre now adopted. A great deal remained yet to be done before we could declare the British flag and British ship to be invulnerable; but nevertheless he (the speaker) believed that by a thorough and earnest devotion to the sciences which bore upon shipbuilding, and the construction of ordnance, we should continue to maintain the supremacy of England on the seas.

A short time since a paragraph appeared in the Boston *Journal*, headed "A Singular Shot," and stating that, at the navy yard at Washington, a 130-pound solid shot fired from a 10-inch smooth bore Dahlgren gun, at a distance of 500 yards from the target, penetrated 4 in. of iron-plating and 10 in. of white oak planking. A correspondent at Washington, who witnessed the experiment, writes to the *Journal*, in order that the facts of the experiment may be stated. He says:—"A 10-inch Dahlgren was charged with 30 pounds of powder and a 130-pound solid shot, and was fired by means of a slow match. The shot made a clean hole through the target, which is composed of one iron plate, 4½ in. thick, and six other plates each 1 in. thick, bolted to a framework of white oak planking 18 in. thick. The target may be about 500 yards distance. These are the main facts as I observed them. Our English and French friends won't think we have made much progress if, on extra occasions, we can only get through 4 in. of iron and a 10-inch oak plank."

A fortnight since a telegraphic despatch was sent from New York city, between three and four o'clock in the afternoon, to San Francisco, and an answer received between six and seven in the evening!

During the battle of Fredericksburgh, the Federals resorted to ballooning to ascertain the position of the Conferate army. The balloon, says a correspondent, rose high in the regions of the upper air, to get a better view of the enemy's land. The morning mist and cannon smoke caused it to come down again. Afterwards, when the atmosphere became clear, it was sent up a second time; this time with better success. One of the rebel batteries directed one of their shells at it. The dangerous missile whistled by its mammoth form in hazardous proximity, but, happily, did no harm to the aerial observers or those congregated in the vicinity.

It always affords us satisfaction to record the results of some successful experiments on iron-plates, to prevent oxidation and fouling. On the 13th of September last, says the *Times*:—Mr. Roper, of New-cross, repaired to Portsmouth, by direction of the Lords of the Admiralty, to prepare a sample of his coating for iron plates to prevent oxidation and to keep clean the bottoms of iron ships. An old and decayed boiler-plate was selected for the purpose, coated with Mr. Roper's preparations, and afterwards sunk within the piers of one of the dockyard jetties. This plate was yesterday raised and examined by the master-shipwright and his staff, and found to be in a very satisfactory condition. Owing to the shortness of the time which the plate has lain under water, it was agreed to prolong the further test of the plate to three months, when more definite results will be obtained. A second plate is also to be prepared by Mr. Roper, in order to furnish the Admiralty with further proof of the anti-corrosive qualities claimed by him for his patent composition. A plate tested at Sheerness Dockyard, and reported upon by Mr. Moody, master-shipwright, has, we are informed, been attended with highly favourable results. We have before referred to the numberless inventions of this kind which have been brought under the notice of the Admiralty, and the failure of the greater number. In fact, no one system has yet been found to possess all the required advantages, and it is now being urged by scientific men that the only plan for securing these advantages is by a system of electrotyping—by depositing zinc, brass, or any alloy upon the plates with a bright enamel surface. A proposal of this kind is now being brought under the notice of the Admiralty.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 1683, 1688.
Boilers and Furnaces—*none.*
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1676, 1677, 1689, 1694.
Ships and Boats, including their fittings—*none.*
Cultivation of the Soil, including agricultural implements and machines, 1681, 1690.
Food and Beverages, including apparatus for preparing food for men and animals, 1684, 1686.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1651, 1655, 1656, 1658, 1665, 1666, 1679, 1685.
Buildings and Building Materials, 1652, 1659, 1682.
Lighting, Heating, and Ventilating, 1670, 1671, 1692, 1696.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1657, 1663, 1668, 1669, 1674, 1698.
Metals, including apparatus for their manufacture, 1661.
Chemistry and Photography—*none.*
Electrical Apparatus—*none.*
Warfare, 1653, 1667.
Letter-Press Printing—*none.*
Miscellaneous, 1654, 1660, 1662, 1667, 1673, 1675, 1678, 1680, 1691, 1693, 1695, 1697, 1700.

1629. J. Morrisson. *Improvements in the construction of springs suitable for ladies' dresses or crinolines, and for chair, sofa, and other seatings, as well as for bedstead and couch sackings.* Dated May 30, 1862.

This consists in twisting, coiling, or spinning flat strips or ribbons of steel, of any width, into a hollow archimedial screw or spiral tube, and applying the same when hardened and tempered to the purpose designated in the title. *Patent abandoned.*

1630. C. O. Staunton. *Improvements in apparatus for signalling and indicating the position of shots on targets in rifle practice and for preventing accidents to the markers.* Dated May 30, 1862.

Here the inventor constructs an upright framework made of wood, metal, or other material, at the top of which he fixes a rod or shaft, and places on it a number of pulleys, which are connected to other pulleys near the bottom of the framework by bands or gearing. To the top pulleys are connected arms carrying discs, and fixed to the shafts of the bottom pulleys; on the exterior framework are handles for working these discs. The discs are painted the requisite colours, such as red for "danger," white for an "outer," and on the framework around the handles for working the discs are painted discs to correspond with the ones at the top. The manner in which the invention is put into operation is as follows:—The marker has this apparatus before him, and when a shot is fired, he is enabled by the discs to indicate the spot at which the target has been struck: for instance, if an "outer" has been scored he turns the handle and displays the white disc at the top of the framework; if a "centre," the blue disc, and so on. The exact position of the shot on the target, whether to the right or left, high or low, can also be shown by inclining the discs in the same direction and at the requisite angle. When the danger signal has to be displayed, he inserts a pin through the handle into the framework to keep in its position. *Patent abandoned.*

1631. H. P. Burt. *Improvements in protecting wooden posts from decay, more particularly applicable to posts for supporting electric telegraph wires* Dated May 30, 1862.

This consists in protecting wooden posts or poles that are fixed in the ground from decay, by wholly or partially surrounding the lower end of the same, which is sunk in the ground with one or more receptacles, containing creosote, or other preservative solution or composition. *Patent completed.*

1632. R. C. Steed. *Improved apparatus for signalling on railways.* Dated May 30, 1862.

This is carried into effect as follows:—In the centre of the space between the "up" and the "down" lines of rails, and at regular distances, wheels are fixed vertically, their axes being supported in proper bearings, and having on their peripheries hand-spokes or levers, for adjusting the position of the wheels. At suitable parts of the peripheries of the wheels projecting arms or flanges are attached, the same being made of a partially elastic material, or so constructed as not to be rigid. Each engine is provided with a bell attached thereto, so that when the said wheels are placed with the arms or flanges at the top thereof, the bell is struck, thereby giving the signal of "danger" to the engine-driver. The bell is fixed to an arm projecting from the side of the engine, such arm being, if desired, partially elastic, and springs being placed on each side thereof, so as to assist the same in returning to its position after the bell has been struck. The wheels are connected together by ropes, wires, or chains, attached to the peripheries thereof, and holding the same in position. By turning the wheels a quarter round, the projecting arms or flanges can be raised or depressed, and the signals put "on" or "off" as may be desired.—*Patent abandoned*

1633. T. N. Pengelly and W. Byron. *Improvements in apparatus for hoisting goods.* Dated May 30, 1862.

Here the inventors mount a traversing nut on a long screw, fitted to rotate in suitable bearings. This screw has rather a rapid pitch, and traverses the nut when rotated, the nut being fitted in a suitable bar-piece, which traverses on guides. To this traversing bar they attach a rope or chain, the other end of which is wound on a barrel, on the same axis of which is fixed a larger barrel or drum, on which the twisting rope or chain is wound and the end fixed; one rope or chain winds in the opposite direction to that of the other, so that when tractive force is applied to unwind the one, it winds up the other, and so hoists the goods. Motion is communicated to the screw by steam or other power transmitted through suitable toothed gearing and catches, whereby the screw may be thrown in and out of gear at pleasure. In hoisting by this apparatus the travelling nut and its carrying bar on completing the necessary lift of the goods, strike against a lever, which operates a clutch fork mounted on the same axis, and so withdraws the gearing driving the screw, leaving it free. At the same time that the traversing bar disengages the gear by the clutch, it throws a weighted brake on to the drum, winding up the twisting rope which holds the goods hoisted in the elevated position until the attendant relieves the weighted brake by treading on a board, or other contrivance, which raises the weight, and relieves the brake, when the goods are free to descend.—*Patent abandoned.*

1634. W. Eddington, jun. *Improvements in apparatus for draining and tilling land.* Dated May 30, 1862.

This relates, 1, to connecting the fore part of a draining plough to the axle by a screw and nut, or otherwise, so that the plough can be raised or lowered as it travels along, thereby enabling the drain to be made level, or at a given incline, independently of the unevenness of the ground, which can be effected by turning the screw or nut by a wheel or handle connected therewith. The patentee places the screw or nut for raising or lowering the fore part of the plough in commuication with the travelling wheels by suitable gearing and clutches, so that the plough and drain may be gradually raised and lowered as it proceeds, whereby to cause a regular fall of the drain on flat lands. 2, To an improved rope for laying the pipes in the drain. The patentee threads on a small wire or rope a number of short tubes or sockets of wood on which the pipes are to be strung, which prevents the wear of the rope in passing through the drain pipes. 3, The patentee employs a framework carrying tines, in combination with a number of double or single torns or mould boards, placed at suitable distances, which follow behind the tines, so that the implement shall perform both scarifying and ridging at one operation. *Patent completed.*

1635. R. E Lofft. *Improvements in small firearms and cartridges.* Dated May 30, 1862.

This consists in fitting the breech end of the barrel with a small chamber, in which a point for the percussion of the detonating powder is disposed and fixed, such powder being contained in a tube which enters the small chamber alluded to, and which is driven up against the point for exploding the charge. *Patent abandoned.*

1636. J. Ives. *Improved machinery for washing and wringing clothes or fabrics.* Dated May 30, 1862.

This consists, principally, in the use of two or more elastic rollers made of vulcanized india-rubber, and mounted and actuated so that the surface speed of both these rollers will be always the same, and consequently there will be no tendency to rub or tear any article or fabric that may be passed between them. *Patent completed.*

1637. A. Gilbey. *Improvements in the construction of packing cases or boxes for holding bottles either full or empty.* Dated May 31, 1862.

This consists in forming cases so as to have certain shelves and supports upon which the bottles are balanced and rest, so that each bottle is isolated from the other and rests upon the shelves and supports. The junction of the neck with the shoulder of the bottle at the one end, and the portion at the bottom of the other end being the strongest parts of the bottle, the patentee arranges the shelves so that these parts shall be supported on whatever side the box may be turned. To effect this he places and fixes within the box, parallel to one of its faces, preferably the bottom, and a distance about equal to the length of the bottle's neck, a shelf, having a series of holes made in it equal to the other face of the box; and parallel with this shelf or partition he fixes another composed of intersecting rails or bars, similar to an ordinary bottle rack bin, composed so that the centre of each opening or space formed by the intersecting bars shall coincide, or nearly so, with the centre of each perforation in the other shelf. The next part of the invention relates to the method adapted in order to cause the lid of the box, when opened, to lie flat back so as to allow another box to be placed on the top, by which arrangement a series of boxes piled one on another will form a complete wire rack or bin. *Patent completed.*

1638. J. H. Holland. *An improvement in traction engines.* Dated May 31, 1862.

This consists in covering traction engines or locomotives, with their boilers, entirely from end to end, with roofs or sides of such a nature as to assimilate them in external appearance to modern omnibuses or railway cars. *Patent completed.*

1639. G. Ermen and R. Smith. *Certain improvements in machinery for spooling and balling sewing thread, silk, yarn, and other fibrous materials.* Dated May 31, 1862.

This consists, 1, in an improved plan, or arrangement, of the spindles upon which the spools are filled with thread. 2, In an improved spooling machine. 3, In an improved change motion for reversing the movement of the traversing frame at the end of each layer of thread as it is wound on the spools. 4, In an improved plan of varying the length of the traverse as the spool fills, which is effected by means of a left and right-handed screw driven by suitable gearing. *Patent completed.*

1640. W. T. Smallwood and W. Wright. *Improvements in waterclosets.* Dated May 31, 1862.

This consists, 1, in simplifying the constructing of the water conducting and stopping media, by placing the same at the front of the closet, 2, In so placing a valve or tap upon the service pipe, and coupling the same thereto, that it may be readily unshipped or detached and replaced at sea, or when out of repair, without removing or disturbing the other part of the closet, thereby rendering the operation capable of being performed by any ordinary workman or person unskilled in the manipulation of these articles. 3, In forming and fitting the plug of the stop tap so as to turn upon or within the spindle carrying a seated valve at the bottom of the soil pan, and in mounting a tumbler lever upon and between the said plug and spindle for actuating the sewer. 4, In so forming the male and female parts or couplings of the plug and spindle that one may be partially moved about their common axis independently of the other, thus providing the means by which a single lever is rendered capable of first opening the tap or valve on the service pipe, and then tipping the valve or pan at the bottom of the soil pan, or *vice versa.* *Patent completed.*

1641. A. Moreau and A. Ernest. *Improvements in electro magnetic machines or apparatus.* Dated May 31, 1862.

This consists in a method of combining and arranging the several parts of electro galvanic machines, whereby the intensity of the current is regulated with facility and a continuous current kept up, instead of giving it off by shocks as at present practised. *Patent completed.*

1642. J. V. De Verge. *A coating called "Enduit anhydro-carbonide," intended to protect iron from rust, and to preserve wood, cloth, paper, and pasteboard used for packing or roofing.* Dated May 31, 1862.

Here the inventor proposes protecting iron from oxydation, and preserving wood and other material by using the carbon produced in the distillation of coal in gas factories and which adheres to the sides of the retorts. This substance, reduced to an impalpable powder, forms a coating or colouring matter which, whether used in powder or mixed with the excipients used in painting, effects the above purposes. *Patent abandoned.*

1643. R. Shortridge. *Improvements in presses for pressing cotton and other articles.* Dated May 31, 1862.

This consists essentially in the employment of a box or well of wood or iron to contain the cotton, &c., to be pressed. The upper part of this box is open, and in it is fitted, loosely, a plate or follower of iron, which rests upon the cotton, which is raised and lowered as desired by a revolving-shaft, connected to the follower by certain suitable mechanical contrivances. *Patent completed.*

1644. D. A. Lamb. *Improvements in railway buffers, or apparatus to relieve concussion on railways.* Dated May 31, 1862.

Here the inventor uses a cylinder containing air, water, or other fluid. The cylinder is placed horizontally, and has a series of weighted valves upon it; a piston works in the cylinder, and at the end of the piston rod a buffer head is placed; this the inventor prefers should be of lead. When the buffer-head is struck, the piston is forced into the cylinder, and the air or fluid escapes by the valves, which are variously weighted, so that, according to the force of the blow, one or more of the valves open. *Patent abandoned.*

1645. H. Watson and J. Millbourn. *Improvements in pulp strainers or knotter-bottoms.* Dated May 31, 1862.

This applies to such strainers, or knotter-bottoms, as are composed of a series of bars, with spaces between them, and consists in forming them in a series of sections, or panels, each formed of a number of bars, which are combined by screw-bolts and nuts, or other fastenings. *Patent completed.*

1646. J. Butterley. *Improvements in ship building, and in rendering ships shot proof.* Dated May 31, 1862.

For the purposes of this invention, in constructing the ribs or framings of ships or vessels, where iron is used planked over with wood, in place of using the sections of iron heretofore employed for the ribs or framing, the patentee employs iron of the following section, generally known as grooved iron, viz., iron bars formed flat on the outer side or surface against which the wood is to be fixed, and formed on the inner side or surface, with flanges at the edges, so as to give strength to the bars, and so, at the same time, to render the inner side or surface suitable to receive the heads or ends of the bolts by which the wood planking is fixed to the ribs or framing; or, in place of the above section, iron of the following description, generally known as bulb iron, may be employed:- The iron ribs are placed transversely across the vessel, so that they run in a vertical direction from the keel upwards; the planks at the outside of this framing are fixed in a direction from stem to stern, or fore and aft; in the space between the ribs a further planking is used. Such second planking is parallel with the ribs, thus running in a vertical direction from the keel upwards; this planking is fixed to the previous planking by bolts, or in any convenient manner, and the seams of both the planking may be caulked. In order to construct a vessel capable of resisting shot, he employs iron frames, or ribs, such as are above described, and to these ribs or frames he bolts iron plates, running longitudinally of the vessel, the edges of the plates which are bolted to the ribs being provided with flanges. *Patent completed.*

1647. J. Villa. *A new and improved method of exhibiting terrestrial and astronomical phenomena, and of facilitating the solution of problems relating thereto, without the aid of calculation.* Dated May 31, 1862.

This consists, 1, Of a grand planisphere, which indicates the measure of time, having both hemispheres laid out with radial mediums and concentric latitudes, and with the antartic pole forming the centre. This planisphere being put in rotation, either by the hand or by clockwork, instantly gives the hour in all countries, and all the longitudinal differences in time, thereby easing geographical studies, and bringing in view all the lands and seas with the utmost convenience, so as to trace sea voyages, and to discover their antipodes. The equator and ecliptic will be found at their proper places, with all the positions of the sun. 2, Of a grand celestial planisphere with a terrestrial girdle. This planisphere represents the entire heavens on a singular circular plane, indicating all the constellations visible there, by the naked eye, in their angular positions. Surrounding this planisphere, there is a girdle in which is portrayed an epitome of all the countries of the earth, so that they may be found at once in their longitudinal positions. In this system the earth is made immoveable, and the celestial planisphere moves in sidereal time. *Patent abandoned.*

1648. F. F. Lawden. *Improvements in certain descriptions of single and double barrelled guns.* Dated May 31, 1862.

This relates to that description of breech-loading guns, known as "Lefaucheux's," and consists in means for locking the barrel or barrels in position. The invention also relates to that description of guns used as walking sticks. The barrel is jointed by being tapped and screwed or otherwise united above five-eighths of its length from the muzzle upward, and by this joint the breech of the barrel is exposed for receiving the charge, using for this purpose the metallic case cartridge and ball manufactured by Tipping and Lawden, in connection with Sharp's patent repeating breech loading pistol. *Patent completed.*

1649. G. C. Lingham and J. Nicklin. *An improved crinoline connector and suspender.* Dated May 31, 1862.

This consists in cutting out strips of metal by the aid of suitable press tools, with projecting ears at the ends, and in the middle, together with suitable teeth, that project in the proper direction for holding the crinoline to be encompassed. *Patent abandoned.*

1650. L. Chanbart. *An improved mode of raising the level of water in rivers, canals, and other watercourses, and in the apparatus connected therewith.* Dated May 31, 1862.

This consists in the construction of a self-acting and regulating bar, or sluice, applicable to watercourses in general. The bar, or sluice, is constructed in three different parts, which may be employed either together or separately. The details of construction are voluminous, and cannot be produced here *in extenso.* *Patent completed.*

1651. W. E. Newton. *Improvements in the treatment of cloth and other textures, leather, or animal tissues, for the purpose of rendering them more durable and impermeable to water and other fluids, and for producing from any fibrous texture, such as cloth, cotton, woollen, or mixed goods, a durable, artificial leather.* (A communication.) Dated May 31, 1862.

This consists, 1, in giving increased body, and durability, and impenetrability, to vegetable, woody, and animal, fibrous textures, as silks, woollens, leather, gelatinous tissue, prunella, cotton, &c., by first subjecting them to the action of a solution of alumina (or its basic salts), or other true mordant and gelatine, in such proportions, and so as to chemically combine the alumina and gelatine, and form an insoluble composition, which combines chemically with the fibre of the cloth, making the three a chemical compound, and, subsequently, subjecting the said goods to the series of actions, operations, or processes, of the chemical and other agents employed, as described, so that by the various processes and substances employed, substance is added to fibrous tissue, and the materials are chemically united together, thereby forming a compact body possessing great tenacity, flexibility, and, at the same time, being waterproof. 2, In producing artificial leather from any kind of firm cloth, cotton, woollen, or mixed goods, by first immersing the cloth in sulphate of alumina, or the true mordants, then in a solution of tamine, and subjecting it to the various processes, substances, manipulations, and applications, as set forth. *Patent completed.*

1652. W. K. Sullivan. *Improvements in the preservation of stone, plaster, cement, and other like matters, the invention being likewise applicable to the manufacture of artificial stone, and to the fixation and production of colours on and in the body of stone, plaster, or cement.* Dated May 31, 1862.

The chief object here is to impregnate stone, cement, &c., with chemical substances that will render the same impervious to, or capable of resisting the effects of damp. To this end the inventor applies fluo silicate of magnesia, fluo silicate of zinc, or other soluble fluo silicate, to the stone plaster or cement, and then decomposes the same by the applicaaion of a solution of an aluminate of potash or soda, or both, successively, or by a silicate of alumina, dissolved in an alkaline solution. He applies the solutions by a brush, syringe, or hose, in the case of buildings, or, where practicable, by immersion. In general, he prefers the stone, &c., to be damp, and, in order to make it so, he prefers applying a weak solution of silicate of potash instead of water, merely. *Patent abandoned.*

1653. W. E. Newton. *Improvements in the construction and operation of shot proof gun towers, and the working of the guns therein for sea vessels, floating harbour defences, forts, or land fortifications,* (A communication.) Dated May 31, 1862.

The principal points of novelty here are, 1, Placing the gun tower, shield, or cupola upon a rotating bed or base, and arranging the steam cylinders, and the necessary appliances for working them, and the tower, and the guns, so that they shall turn with the tower. 2, Connecting the gun carriage with the pistons of steam cylinders, so that the guns may not only be run out of their ports, or back into the tower by steam power, but that the recoil of the guns, when discharged, may be taken up or counteracted by the elastic force of the steam on the cylinders. 3, Making the gun tower cupola, or shietd of much smaller dimensions than has been heretofore proposed, and constructing in it sections something like a telescope gas holder, so that the top section may be lowered into the hold of the vessel when required for the pupose of lowering the centre of gravity of the vessel and thereby preventing it from rolling in a rough sea. 4, Levelling the gun in the tower, in the act of raising it by means of a projecting stud, pin, or stop piece, placed near its muzzle, in combination with a fixed guide on the tower, so that, as the gun rises, the stop piece therein, by coming in contact with a fixed guide, may so point the gun that a very small port only will be required, as the gun must by this arrangement for pointing it enter the port fairly without striking the sides of the port. *Patent completed.*

1654. B. Tanplar. *Improvements in apparatus for registering and indicating billiards and other games.* Dated June 2, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1655. J. King and J. Partington. *Certain improvements in looms for weaving.* Dated June 2, 1862.

This invention is not described apart from the drawings. *Patent completed,*

1656. J. Elce and W. J. Gradwell. *Certain improvements in machinery for spinning, doubling, and winding cotton and other fibrous substances.* Dated June 2, 1862.

The first part of this is particularly applicable to the machines for spinning called thrastles, and to other machines of the like nature for doubling and winding, in which two pin cylinders are used for driving the spindles by band, and it consists in causing the two cylinders to approach each other simultaneously, for the purpose of slackening the band when it is requisite to turn the spindles by hand for removing the flyers previous to doffing the fall bobbins, and for replacing the flyers. The second part is applicable to those machinery used in spinning, doubling, and carding, in which the spindles are driven by tapes passing over a centre cylinder, and then around guide pulleys supported in elbow levers, and it consists in actuating all the elbow levers on one side of the machine by a shaft and eccentrics, or other equivalent agents, for the purpose of slackening the tapes simultaneously. *Patent abandoned.*

1657. A. J. Sax. *Improvements in kettle, big, or other drums.* Dated June 2, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1658. T. Campbell. *Improvements in apparatus for "witneying" piled fabrics.* Dated June 2, 1862.

This consists in arranging the rubbers so as to diminish the pressure on the surface of the cloth or fabric, which the inventor effects by suspending the levers to which the rubbers are connected at such height above the surface of the cloth that heat is not evolved through the great pressure of the rubbers; also in applying heat through pipes or otherwise, for the purpose of imparting to the cloth or fabric the amount of heat required to facilitate the process of "witneying," thereby obviating the present inconvenience arising from the great pressure of the rubbers on the cloth or fabric. Also a kind of cushion of cotton pile, or other material, is fixed under the cloth, opposite to the operating surface of each rubber. *Patent abandoned.*

1659. C. H. Roeckner. *An improved method of constructing coffer dams and other similar structures for excluding or keeping back the flow of water, and preventing inundations.* Dated June 2, 1862.

This consists in driving piles across the bed of a river, or other water-course, at some distance from each other—say, 2, 3, or 4 ft. asunder, and in employing a strong woven material, or fabric, such as sail-cloth, rendered waterproof by any known means, for the purpose of keeping out the water, the fabric being placed along the pile, reaching from the top thereof to the bed of the river, or other water-course. *Patent abandoned.*

1660. J. Baker. *Improvements in pumps.* Dated June 2, 1862.

This relates to the arrangement and construction of pumps, more especially those of the portable kind, which are specially adapted for the use of horticulturalists, &c. According to one modification the pump consists of a brass barrel, to the lower end of which is attached a ring which is connected by two curved stays to a foot-plate beneath. To the lower part of the pump barrel is screwed the box or chamber in which the inlet valve is fitted. The extremity of the valve-box has screwed to it a short length of bent tubing, to the outer end of which is connected the flexible tubing which serves to convey the water from the source of supply to the pump. A disc valve is fitted in the inlet chamber, and this valve rises with the upward motion of the piston, and the water flows into the barrel. The piston is of the ordinary kind, and is attached to a rod passing out through a stuffing-box at the upper end of the barrel, and terminating in a cross handle or hand lever. The downward pressure of the piston forces the water through a laterally projecting tube, which communicales with the outlet valve chamber. The outlet valve opens upwards into a small chamber of a spheroidal figure, the upper part of which communicates with the outlet tube: to this is screwed the flexible tube and jet-piece for directing the stream of water in any required direction. *Patent abandoned*

1661. J. Key and F. Potts. *Certain means of producing designs in iron, and in the application of the same, or designs formed in like manner of other metals to the manufacturing and ornamenting of bedsteads and other metal articles of furniture.* Dated June 2, 1862.

The patentee claims the applidation of the process of rolling to the production of designs in wrought-iron, the same to be used for the manufacture of metallic bedsteads, couches, chairs, flower-stands, &c., &c., as described. *Patent completed.*

1662. C. E. Gray. *Improvements to apparatus for extracting, rendering, receiving, purifying, cooling down, and delivering oleaginous and fatty matters, or other material treated by steam pressure for extraction.*

The patentee claims the use or application, in the treatment of fatty or oleaginous matters, or for other similar purposes, of a closed steam-tight vessel or digestor, in combination with a receiver or second vessel for the purposes of treating, that is to say, smelting, purifying, and drawing off under pressure the fluid portions of such matters for the objects and purposes described. 2, The use and application in the treatment of the aforesaid matters and like purposes, in combination with a digestor or other similar vessels of a steam-tight receiver, or second vessel, as a recipient for the fluid portions of the aforesaid matters heated under pressure, for the purpose of allowing the same to cool down to the temperature at which they may, without injury, be exposed to the atmosphere for the reasons and purposes drscribed. 3, The use and application of a jointed or moveable pipe, with or without a strainer, rendered buoyant by a float or otherwise, and having its outlet at the lower part of the vessel to which it may be attached, for the purpose of drawing off the supernatant fluid contents of the vessel or vessels. 4, The application of the drying apparatus, as described, for the purposes specified. *Patent completed.*

1663. J. WHITWORTH. *Improvements in shells.* Dated June 2, 1862.

According to this invention shells are made of metal properly hardened. They are solid for a sufficient length in front of the internal cavity to give the requisite strength for penetration. The fuse usually employed for igniting the bursting charge is dispensed with, as the heat generated by the impact of the shell is sufficient to ignite the charge. To prevent the heat generated by impact from acting prematurely, and to regulate the time of ignition, the bursting charge is surrounded by a proper thickness of flannel or other material which is a non-conductor of heat. The body of the shell the patentee makes of the metal known as homogenous iron, or of very mild, lowly carbonized steel: the metal is by the makers of homogenous iron cast into an ingot, and hammered so as to produce a bar of suitable section. Having obtained such a bar, forged approximately to the form of the shells, he cuts it into lengths, each sufficient to form two shells: these lengths are then what is technically termed converted, so as to render the exterior part more highly carbonized, and therefore harder than the interior, to a depth of from a quarter to half an inch. These pieces he divides (and brings to the form shown in the drawing), boring them internally, and turning and cutting them externally. This being done, he puts the body of the shell into an iron box, and surrounds it with animal charcoal, cuttings of horn, and such like materials ordinarily employed in the process of case-hardening, and, as is usual in that process, he heats the box with the body of the shell within it to a red heat. He then withdraws it, still red hot, from the box, and having set it up on end, he causes numerous jets of cold water, by preference brine, to play both on its outer and inner surfaces, thus the shell body is rapidly cooled and rendered hard. In this state, however, it is more brittle than is desirable: this he obviates by tempering it, for which purpose he places it with its base on a block of metal heated to dull redness, and allows it to remain there until a straw colour at the front and a blue colour at the rear indicate that it is tempered to the proper degree *Patent completed.*

1664. W. E. NEWTON. *An improved mode of making the handles of shovels, spades, dung forks, and othera nalagous articles.* (A communication.) Dated June 2, 1862.

This consists in forming the eye of the handle by splitting or sawing in a horizontal direction, for a suitable distance, the end of the bar or shaft of which the wooden handle of this implement is composed, and then bending out into the form of a fork the parts formed by the split or key. The holder is then secured between the ends of the fork in any convenient way, and the parts are held together by a tie rod with screwed ends. *Patent completed.*

1665. E. LLOYD. *Improvements in machinery for the manufacture of paper.* Dated June 2, 1862.

The patentee claims—1, Operating in the manner set forth upon vegetable fibres, preparatory to converting them into pulp for the manufacture of paper, in a close vessel or boiler, either fixed or moveable, and provided with a perforated false bottom or lining, and into which boiler or close vessel steam, water, or air is or are admitted for the purposes set forth. 2, Lining the sides and bottom of the bleaching, poaching, and beating vessels, with perforated metal, so that the liquor may be drawn off without removing the fibres. 3, Countersinking the holes made in the perforated metal employed in the bleaching, poaching, or beating vessel, and also in the close vessel or boiler, as described. Lastly, adapting to the delivery end of the paper-making machine a shifting or movable table to receive the paper as it is delivered from the machine, as and for the purpose set forth.—*Patent completed.*

1666. A. V. NEWTON. *Improved machinery for breaking and cleaning flax and other like fibre-yielding plants.* (A communication.) Dated June 2, 1862.

This invention is not described apart from the drawings. *Patent completed*

1667. J. MARSON. *A new or improved projectile for small arms and ordnance of every description.* Dated June 2, 1862.

These projectiles are well adapted for smooth bores, because they rotate of themselves, by being propelled through the air; and this object is attained by making the projectile with helical, or winding passages, around its axis. The centre of the axis may be solid or concave, but the inventor prefers the cavity of the form of the exterior, which exterior he sometimes makes of a parallel or cylindrical body, and conical apex or point, the base being flat. *Patent abandoned.*

1668. J. H. GEBHARDT. *An improved fastening for bags, purses, and other similar articles.* (A communication.) Dated June 2, 1862.

This consists of an improved fastening, in which is a lever, so arranged that, when depressed at one end, it depresses a spring placed beneath it, and thereby releases from each other the two engaging parts of the fastening, but when the lever is released or restored to its previous position it allows the spring to rise, and the engaging parts of the fastening (supposing them placed together) to be again engaged. The lever is worked from outside the bag, &c., by a handle, finger-piece or end, on raising which, or moving it in an upward direction, the opposite, or inner, end of the bar is depressed, the spring forced down, and the fastening opened. *Patent completed.*

1669. T. L. SCOWEN. *The ocular demonstrater of time in music and accentor.* Dated June 3, 1862.

This consists in having spaces marked on a dial or tube, the dial representing different length bars in music equally divided, and hands, or pointers worked by clock work, pass at an equal rate from left to right successively, which will show the exact time each of the various length notes or rests is to be held, or continued, and a hammer with such arrangements as to cause it to give a louder beat at the executed parts of different bars. The accent is indicated or produced by the higher teeth in a star framed wheel; the whole is set in motion by a train of wheels with spring barrel or weight, and regulated to the different degrees of quickness or slowness by an expanding fly. *Patent abandoned.*

1670. C. GURNEY. *Improvements in apparatus for production and application of artificial light.* Dated June 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1671. W. H. HALL. *Improvements in miners' safety lamps.* Dated June 3, 1862.

This consists in the manufacture of the Davy or safety lamp with a spring lock, and superior wire gauge. The superior wire gauge is made by forming the woven wire-work into the usual or suitable shapes, and then tinning or galvanizing them; this process solders the seam and strengthens them entirely. *Patent abandoned.*

1673. J. BIERS. *Improvements in shoes for horses and other animals.* Dated June 3, 1862.

For the purposes of this invention in making shoes, the under surfaces are formed with projections at intervals apart, there being spaces between the neighbouring projections. This part of the construction does not materially differ from what has before been done in the making of some kinds of shoes, but according to this invention, in place of the upper surfaces of shoes being as heretofore when they have been made with projections or roughings on their under sides, they are, according to these improvements, made with indents or cavities opposite where the projections are produced on the under sides, so that the projections are hollow on the upper surfaces of the shoes, thus forming undulations or corrugations, by which means shoes are made extremely strong, and at the same time comparatively light. In order to fasten such shoes to the feet of horses and other animals, the outer edges of the upper surface of a shoe are made to fit as heretofore against the under surface of the outer edges of the hoof. For this purpose the undulations or corrugations of the metal do not proceed to the outer edges of a shoe, but stop short, so as to leave a sufficient width to fit against a hoof, and to receive the nails. *Patent completed.*

1674. S. WESTON. *Improvements in trusses.* Dated June 3, 1862.

In carrying out this invention the pad is mounted on and carried by a metal disc or plate, which has two studs or projections thereon, which enter through holes in the back of the pad. On either side of these studs or projections is a half elliptical spring, which is fixed to the disc or plate so that the ends of the springs rest against and press the pad outwards, yet allow of its moving on the projections or studs in any direction. On the disc or plate is attached one end of a bent wire or rod, by means of a pin joint, so that it is capable of movement. This bent wire or rod ascends up nearly to the hip. At the other end of this wire or rod there is a hook or other means of attaching it to a strap, which passes over the hip and behind the back of the person who is wearing the truss. The other end of this strap is then passed over the other hip, and is attached to the end of another wire or rod, which is, by its other end, fixed to the disc or plate, and ascends some distance from the disc up towards the hip last mentioned. One end of a second strap is attached to the end of another wire or rod, which is also attached to the disc or plate, and descends some distance below it. This strap passes between the legs of the person wearing the truss, and then ascends up behind the person in an inclined direction, and is made fast to the other strap near where it passes over the hip last mentioned. *Patent completed.*

1675. J. L. NORTON. *Improvements in machinery for raising and forcing water.* Dated, June 3, 1862.

This invention is applicable to pumps where diagrams or flexible partitions are employed, as well as to other forms of pumps, and consists in applying the suction or induction pipes or inlet at the upper part of the cylinder or chamber of a pump, within which the piston or diaphragm works, so that the cylinder, or chamber of the pump, is at all times charged with water, even though the pumps be defective; and, further, in combining with pumps, whether they be double or single-acting, a peculiar arrangement of valves. For this purpose the inlet and outlet valves are placed at, or above, the upper parts of the cylinders, or chambers of the pumps, and the outlet valves are arranged above the inlet valves, which are placed in suitable boxes, or compartments, exterior of the cylinders, or chambers, of the pumps, but connected with them by suitable passages to admit of the valves being readily got at. The inlet and outlet valves are arranged over the upper ends of the suction pipes of the pumps. *Patent completed.*

1676. J. FINCHAM. *An arrangement, or arrangements, of mechanism useful for facilitating the repairing of roads and ways; also applicable to the tilling of land.* Dated June 3, 1862.

In carrying out this invention a frame is constructed composed of bars of iron, or other metal or material, the said frame having the form of a square, or other convenient figure, such frame being provided with guides for the purposes hereafter described, the whole being mounted upon wheels (three being the number preferred), the axle of the front wheels forming part of, or being properly secured to, the said frame, and the hinder wheel being secured as hereafter described. To the front part of the above-named frame is attached (as hereafter described) the after-mentioned rake arrangements, and nearer to the back, or handle, part of the machine than to the rake, there are arrangements of scrapers provided to follow the said rake when in use, and scrape together the stones, roadstuff, and the like. To make the connection between the said rake arrangements and the frame aforesaid, long pairs, or slide bars, are used, which work in the guides above-mentioned, these guides crossing one another at right angles, or nearly so, by which arrangements the said scrapers may (within the limits of the guides) be moved to a greater or less angle, as may be required, scraping the filth from off the roads, by allowing the angle of the scrapers to be reversed for levelling the roads. The said pins, or slide bars, are provided with such screws, nuts, or heads as shall keep the scraper arrangements steady and secured to the frame aforesaid, but with capability of travelling on the guides when desired. Handles, or levers, are attached to the said scraper arrangements for lifting and also for pressing the same down upon the road. For tilling land, the scraper arrangements and the rake arrangement can, if required, be removed, and agricultural hoes, rakes, harrows, or scarifiers, be substituted in the place of the rake aforesaid, and thus this machine may be rendered also appreciable to the tilling of land. *Patent completed.*

1677. A. H. PERRY. *Improvements in fastenings for and in the method of fastening together, or securing railway chairs and sleepers, and for other similar purposes.* Dated June 4, 1862.

Instead of employing the ordinary solid or compressed wooden trenails alone, and instead of using iron spikes of any convenient shape or form alone, for securing iron chairs to the wooden sleepers of railways, as is now commonly practised, the patentee forms a hollow or tubular wooden trenail, and uses in combination therewith a novel shaped metal spike. He takes a wooden trenail either turned parallel with a head or shoulder, or with any suitable amount of taper, and he bores a hole along its axis; he also takes an iron spike or round metal pin, with a head, and he flattens it at some distance above the point, but he prefers to leave the point cylindrical, so that there is a square shoulder formed on two sides by the flattening. For the purpose of fastening iron chairs on wooden sleepers he first bores the sleeper or other substance, and then drives the hollow wooden trenail through the hole in the chair and into the wooden sleeper to the required extent; he then drives the novel description of spike or pin into the hollow trenail, which is thereby expanded at its lower end, and thus forms a dovetail within the wood, which will prevent the trenail from being withdrawn from the sleeper, as also the spike or pin from being withdrawn out of the trenail. *Patent completed.*

1678. G. PEEL, and J. SIMPSON. *Improvements in the construction, arrangement, and mode of working hydraulic presses.* Dated June 4, 1862.

These improvements in the construction of hydraulic presses consist in making the cylinders and rams of steel, instead of cast-iron, as heretofore customary, in making the columns of steel instead of wrought-iron, and in making the framing for the top and bottom of the press of wrought-iron or steel, either alone or combined with cast-iron or other materials, instead of entirely of cast-iron, the object being to unite great strength with comparative lightness. The improvement in the arrangement of hydraulic presses consists in making the rams and cylinders to work within each other, in the same manner as the slides of a telescope; the largest ram works within a stationary cylinder, and the smaller ram works within the larger ram, which acts as a cylinder, and in this way two or more rams of different diameters may be acted upon successively to increase the power of the press as the speed diminishes. When the smaller or smallest ram has been raised, self-acting blocks come into action to support the follower, which is then carried forward by the action of the succeeding ram. The improvement in the mode of working hydraulic presses consists in forcing the water that has been used to raise the ram or rams into an air vessel in which it accumulates under pressure, and in conveying this water again into the cylinder or cylinders of the press for the purpose of partially raising the ram or rams during the next operation. By this means the rams are rapidly raised, while the pressure to be overcome is small, thus economizing power and time in working the hydraulic press. The air vessel may be charged direct by the pumps when the pumps are not required for working the press. The improved arrangement of force pumps for hydraulic presses consists in connecting the plungers of two or more pumps to a beam working on a fulcrum, the piston-rod of a steam cylinder direct to one or both ends of the beam, thereby applying the power in the most convenient manner for working any convenient number of force pumps. The pumps are, or may be, of different diameters, and they are provided with self-acting valves, so that, as the resistance increases, the larger pumps are successively thrown out of action. *Patent completed.*

1679. C. S. CAHILL. *Improvements in the manufacture of felted fabrics suitable for hats, bonnets, and other purposes.* Dated June 4, 1862.

The first part of this invention consists in preparing such felted fabrics by taking a body, foundation, or form of suitable shape made of paper, paper pulp, calico, linen, or other woven fabric, and applying to it a coating of varnish, shellac, india-rubber in solution, size, glue, or other suitable adhesive material, upon which the inventor applies a sufficient quantity of ground or properly prepared flock, wool, silk, cotton, or other suitable fibrous material, which is then pressed and worked to a proper surface; and if not of sufficient substance, an additional coat or coats of the adhesive material may be applied, and additional quantities of the felting or other materials may be added. *Patent abandoned.*

1680. W. JAMES. *Improvements in bolts, spikes, and nails, and in apparatus for their manufacture.* Dated June 4, 1862.

This invention consists in making bolts, spikes, and nails, of round spiral-grooved rods, and in a peculiar apparatus for producing the twist in the rod during the process of manufacture. The metal rods, of which these articles are manufactured, are first rolled with one or more straight grooves or channels. To give the required spiral direction to the grooves or channels, the rods are afterwards twisted, and, finally, the bolts, spikes, or nails, are headed in the usual manner. For the purpose of producing the twist in the metal rod, a simple box or cylinder is used, with a perforation slightly larger than the rod itself, on which perforaon spiral protections are formed equal in number to the grooves on the rod, and varying in size and form according to the size and desired curvation of the grooves or chambers in the finished articles. The metal rod coming from the rollers passes into and is forced through the said box or cylinder, thereby twisting the rod more or less, the degree of twist depending upon the form of construction employed for the inside of the box or cylinder. This twist or spiral form, however, may be given, though not so conveniently, by the ordinary means to each length separately, either before or after the bolt, spike, or nail is headed. When one of these bolts, spikes, or nails is driven into a hole somewhat smaller than the said bolt, spike, or nail, it passes through spirally or in a manner similar to that of a screw, and it retains its position with a much greater tenacity than the ordinary bolt, spike, or screw. *Patent completed*

1681. J. Allcock. *Improvements in the construction of horse rakes.* Dated June 4, 1862.

This invention consists, 1, In placing a boss on the inner side of the machine at each end thereof, and in bringing this boss nearly throughout its length, but leaving its inner end closed. In this bored boss the patentee fits a turned axle, and the other end of the axle he inserts and secures in the nave of the wheel. He also cuts a groove round that end of the axle which is placed in the boss, and passes a set screw through the boss, the end of this screw taking into the groove, and thereby securing the axle fast into the boss, but leaving it (the axle) free to revolve. The improvements next consist in the following improved mode of altering or varying the pitch of the teeth. For this purpose he places two or more transverse bars in the machine, upon each of which bars he places a clip: these clips embrace the bars, and have a series of holes in them, through which he passes spring cotters, the cotters also passing through holes in the transverse bars, that is to say, each cotter passes through one of the holes in one of the clips, and through a hole in the transverse bar embraced by such clip. The lever bar on which the teeth of the rake rest lies on the top of clips, so that the pitch of the teeth is regulated by the height at which the clips are placed and secured on the bars. The teeth can thus be set either to touch the ground, or just to clear it, or they may be raised up to the highest point required. There is attached to the machine a presser bar, which works on the top side of the teeth, for the purpose of making the teeth hold closer to their work. *Patent completed.*

1682. R. Roe. *Improvements in planes for tongueing, working sash fillisters, or other similar purposes.* Dated June 4, 1862.

The object of this invention is to supersede the necessity for the numerous planes required by a carpenter or joiner for preparing the tongues used in the various operations of carpentry, and for the purpose of carrying out these improvements, the inventor makes the plane with an adjustable fence, similar to those used in a "plough" or "side fillister plane," having two planes similar to those known as rabbet planes, working on a bar, so as to keep them perfectly parallel and true with one another. These planes are also provided with a "stop" which regulates the depth to which the tongue shall be cut, and they are provided with suitable adjusting and set screws, so as to enable the workman to make the tongue of any desired width, depth, or position, on the plank or other piece of wood operated upon. *Patent abandoned.*

1683. G. Allibon and E. Snell. *Improvements in surface condensers and superheaters.* Dated June 4, 1862.

This invention relates to the construction of tubulous vessels, in which the steam or vapour to be cooled or condensed, or superheated, or charged with additional degrees of heat, as the case may be, is made to pass from one chamber or passage, by means of a bent tube, into another chamber or passage—the cooling or heating, or the heat abstracting or superheating (as the case may be), being effected within the main casing, and through the external surfaces of the bent tubes. The apparatus may consist of a vessel divided into two parts by a tube-plate, in which the two ends of each of the bent tubes are secured, the larger portion of the chamber being occupied by the tubes, and the smaller portion being occupied by a number of divisions or plates forming chambers or passage ways, alternately arranged for the in-going or out-coming of the steam, which is made to pass through the legs of each of the bent pipes. Or, instead of the apparatus being formed of one vessel only, the tubulous portion may be one vessel, and the divisional or cellular portion for the inward and the outward passage of the steam may be another vessel, and these two may be bolted together, or otherwise connected. For surface condensers, the patentees prefer to make the case, or external shell, of cast iron, although it may be constructed of any other metal—and where horizontal layers of bent tubes are preferred, the front and back of the condenser should each be enclosed or secured by a perfectly air-tight cover, so that ready access may, when necessary, be had to the interior. Each of the passage ways devoted to the exhaust should be connected with a bottom chamber or general receiver for the condensed water, whilst the steam passages are in the like manner connected together from the steam exhaust pipe. The bent ends of the pipes, which are free to expand and contract, may be supported either on bearing pieces cast with the back cover, or they may be supported on bearing bars or independent bearers arranged within the case. The two ends of each bent pipe being secured in the same tube-plate, in each case the one leg communicates with the steam passage or chamber, and the other leg with the exhaust or condensor, the bent tubes being one above the other: for each set of vertical passages the number of vertical series may be increased, according to the space which can be afforded to the width of the condenser, and according to the condensing surface or area required. For superheaters they prefer to employ an apparatus generally similar to that described as intended for the condensation of steam, although the proportions, as well as the details of the arrangement, should be varied to render it more suitabte for the special purpose and the position of the application; but generally they prefer to add an exterior casing surrounding the shell, within which the heating operation is performed, and within which interior shell is contained the bent tubes through which the steam to be superheased is made to pass. *Patent completed.*

1684. G. B. Toselli. *Improvements in apparatus for freezing and cooling liquids.* Dated June 4, 1862.

This invention consists in arranging an apparatus so as to give it a horizontal rotary motion, in order that the refrigerating compound shall receive a vertical motion, so that it shall act quietly and efficaciously, and also to change continually the positions of the liquids to be congealed for the purpose of disengaging the air. *Patent completed.*

1685. J. and G. Battinson. *Improvements in machinery for combing wool and other fibres.* Dated June 4, 1862.

In carrying out this invention the inventors make the combs and lifters straight, except the front ones, or those next to the circular comb, filling up the angles or spaces betwixt the straight and curved ones at each end by short rows of combs or teeth and lifters. By this means they can produce better work and in greater quantity than heretofore. *Patent abandoned.*

1686. G. H. Sanborn. *Improvements in refrigerators.* (A communication.) Dated June 4, 1862.

These refrigerators are constructed of any desired form and size. The materials found most suitable for this purpose are galvanised iron or zinc. In the top of the said refrigerator is an ice chamber, and between the exterior wall and the interior wall there is a space designed for cold air and ice-water, extending round the vessel, except that part occupied by the door. The water is drawn from this space in the usual manner. The inventor employs the cylindrical form, which is the most convenient and otherwise desirable. The shelves rest on supports fixed to the interior wall, and on the bottom is placed a table, constructed to revolve for convenience of access to the contents of the refrigerator. *Patent completed.*

1687. F. P. Preston and C. Goodman. *Improvements in the permanent way of railways.* Dated June 4, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

1688. E. Scheutz. *Improvements in rotary engines.* Dated June 4, 1862.

This invention relates to a previous patent dated 30th Oct., 1860 (No. 2656), and consists in so constructing such engines as to enable them to be worked expansively if desired. For this purpose a steam port is made to open into one end of the cylinder at the side thereof, communicating with the valve chest and another port communicating with the former one and the steam pipe; and the end of the piston at that part has a number of chambers or recesses formed in the surface thereof, such chambers or recesses being made to travel in front of the steam ports above referred to, and, consequently, they alternately open and close the communication between those ports, thereby cutting off the steam at any previously determined part of the revolution of the piston. A direct steam communication is also made with the valve chest, and a cock or valve is fitted therein, so that the steam may either be led at once to the valve chest by opening the cock, or the cock may be closed and steam diverted through the separate passage, and through the steam ports above referred to, in which latter case the engine will work expansively. *Patent completed.*

1689. S. Huston. *Improvements in safety valves.* Dated June 4, 1862.

For the purposes of this invention two valves are used on the same spindle or stem, one being of larger diameter than the other, and the steam is caused to act in such manner as to pass one towards its seat and the other off its seat. The spindle or stem of the two valves is hollow from the upper end thereof to nearly the lower end thereof, in order that it may receive a short rod, which is pin jointed to the weighted lever, by which the valves are pressed into their respective seats. Below the seat of the lower valve is a pipe, by which the steam which escapes from under the lower valve is conducted away, and, if desired, the steam passing the upper valve may also be conducted away by a pipe, or it may be allowed to escape directiy into the outer atmosphere. By these arrangements the steam in a boiler is constantly tending to open the valve having the larger area, while the steam is tending to close the valve, having the smaller area, and the weighted lever is constantly tending to press both the valves to their seats. *Patent abandoned.*

1690. A. V. Newton. *Improvements in the construction of grain and grass harvesters.* (A communication.) Dated June 4, 1862.

This invention has for its object to make a grain and grass harvester, capable in its general construction, and in its operation, of being changed from a grass mower into a grain reaper, and *vice versa*, and yet perform effectually the functions due to each operation, which differ in some material points. Thus, for instance, in cutting grass, the cutting apparatus must run close to the ground, and receive all its rising and falling motions from the ground over which it (the cutting apparatus) passes, and uninfluenced by the inequalities of the ground over which the driving or supporting wheel (or wheels) passes. In cutting grain, the cutting apparatus must be set up above the ground at a suitable height, and be there maintained, in a firm, rigid manner, but so that it may be raised to pass any intervening obstruction, or adjusted from time to time, as circumstances may require. For one purpose, therefore, the cutter, or finger bar, must be flexible, and follow the undulations of the ground over which it passes, but under the control of the operator tending the machine, and for the other it must be rigid, and be carried, at a fixed distance, above the ground, uninfluenced, certainly, by the ground over which the driving or supporting wheel (or wheels) passes; but, when mowing grass, it is always under the control of the operater, who rides upon the machine, and, with a lever, or its equivalent, governs the cutting apparatus as to height, and raises it over any obstruction in its path. The invention cannot be described in detail without reference to the drawings. *Patent abandoned.*

1691. E. Conroy. *Improved machinery for cutting corks, bungs, and such like articles.* Dated June 4, 1862.

This invention relates to various improvements upon a machine for cutting corks and bungs, for which letters patent were granted to Alfred Vincent Newton, dated the 18th day of June, 1859, and consists in cutting pieces of cork, that have been previously prepared, of suitable dimensions, or, as they are termed, "quarters," into cylindrical or conical corks or bungs, by means of a rotating circular disc cutter, or plate. The frame, or shaft, which carries this revolving disc, or cutter plate, has an upward and downward motion communicated to it when required. These motions are governed by a cam, mounted upon the main shaft, and the object of this arrangement is to enable the rotating disc, or cutter, to make two distinct cuts on the same piece of cork. One of these cuts will simply cut off the rough sides and angles of the "quarter," and the other will make a finer and finishing cut, which will complete the cork. Both of these cuts are effected during two revolutions of the "quarter" between the suspending or holding pivots. Another improvement in this machine consists in giving to the clamps, or pivots (used in holding the "quarters" to be cut or rounded), and also to the sliding feeder, considerable facilities for self-adjustment, should any variation occur in the length of the cork, or "quarter," to be cut. The clamps, or pivots, or the pivot and tube between which the block, or "quarter," to be cut is held, are both mounted with helical or other springs, and the face of the feeder is made capable of a slight lateral adjustment by means of a spring slide, thus avoiding the probability of compressing the cork more than is necessary to hold it during the process of cutting or rounding. *Patent completed.*

1692. G. Rydill. *An improved hydraulic pump, or engine, for raising liquids and obtaining motive power, also applicable for the ventilation of mines, and other useful purposes.* Dated June 5, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1693. J. E. Moiroux. *A new compound for protecting and preserving the polish, polished, and other surfaces of metals, woods, skins, and paper, and for rendering all woven textile and other fabrics water and weather-proof.* Dated June 5, 1862.

This compound, or liquid, is produced by the chemical action of acids, water, and ether in the quintessence of alcohol upon silk, cotton, or other vegetable matter, by which the latter is decomposed, dissolved, and converted into a liquid state, so as to combine or mix with the rectified spirit, and form a limpid transparent gum or compound possessing the properties above-mentioned. The liquid may be used with colour without losing its properties. *Patent abandoned.*

1694. J. Bell. *Improvements in fastenings for railway chairs.* Dated June 5, 1862.

This invention relates to improved metallic spikes to be substituted for the trenails, or fastenings, by which railway chairs are ordinarily secured upon their sleepers. According to one modification, the improved metallic spike is made of a piece of sheet, or malleable iron or steel, which is bent, or shaped, in dies or moulds, or by means of any other suitable tools that may be in use for like operations, into a tubular form. In this modification the edges of the metal are not brought quite close together, but are left slightly apart, so that the spike may be slightly compressed on being driven home, and its consequent tendency to re-expand will give it a firmer hold in the sleeper. With this view the hole in the sleeper is made a very tight fit for the spike, or even of a slightly less diameter than the uncompressed spike, and the point of the spike is slightly coned, or sharpened, as shown, to facilitate its introduction. *Patent completed.*

1695. R. Robinson. *Improvements in fire-escapes, parts of which improvements are also applicable to other purposes.* Dated June 5, 1862.

This invention consists essentially in constructing a portable machine, consisting of a base, or platform, provided with suitable wheels to allow of the platform and apparatus mounted thereupon being easily and rapidly moved about, or transported from place to place, and in applying to this portable base or platform a series of short ladders, which are elevated by specially arranged gearing, such ladders being guided in their ascent and descent by side guides. The invention also comprises arrangements for working the cage, or basket, intended for the occupant of a burning building. *Patent abandoned.*

1696. J. M. Stanley and J. Stanley. *Improvements in stoves or apparatus for diffusing heat.* Dated June 5, 1862.

This apparatus consists of a fire-box cast in one piece, or in sections, fitted together, the length being about equal to four times its width. This fire-box is raised from the floor upon a hollow pedestal projecting more or less beyond it on every side. The sides of this pedestal are perforated, and in the top thereof a number of apertures are formed, through which perforations or apertures the cold air to be heated enters, and passes through the heated tubes hereafter described. In an opening in the centre of the pedestal a set of fire bars formed to the shape of the fire-box are fitted, and under these bars a sliding ashpit, which draws out at the end, is also fitted; this sliding draw or ash pit encloses the entire area of the grate, but does not project to any considerable extent therefrom more than is sufficient to cover the bar space and regulate the draft thereto. The draw or moveable ash pit is fitted with a valve at the end for regulating the flow of the air to the fire bars, which are cut off from the surrounding atmosphere, or very nearly so, when the slide is closed. The fire-box is closed at the top by a metal arch or roof, by which the products of combustion are conducted to an aperture at the extreme end thereof. Through this aperture they are allowed to pass and return under a second arch or roof, and over the first to a second aperture at the opposite end of the second roof or metal arch, and are again conducted to a third aperture over the first, passing over the second arch and under the covering plate of the stove to an ascending or descending flue therein, by which the smoke and other products of combustion are carried off, and are thus effectually prevented from coming in contact with the surrounding atmosphere of the room or building, the latter being warmed by heat diffused by the circulation of the air through the apertures and tubular passages surrounding the fire-box and traversing the heated chambers of the apparatus. The air which enters the perforated pedestal before described is prevented from passing through the fire grate by the enclosed sliding ash pit, and is conducted from the lower to the upper part of the apparatus through a number of vertical cells or tubes which entirely surround, and are heated by, the fire in the fire-box. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Sept. 1, 1862.

2419. J. Watt, 13, Graham-street, Walworth, chemist, and T. S. Haviside, 69, Cornhill. An improved method of treating flax and other similar vegetable fibrous substances to be used as substitutes for cotton.

Dated Sept. 3, 1862.

2436. F. C. Bakewell, 6, Haverstock-terrace, Hampstead. Improvements in fire-places and stoves. A communication.

Dated Sept. 4, 1862.

2447. J. Platt, Oldham, and W. Richardson, mechanical engineers. Improvements applicable to the burning of bricks, tiles, and other articles of earthenware.

2450. J. Platt, Oldham, and W. Richardson, mechanical engineers. Improvements in the preparation of clay for the manufacture of bricks, tiles, and other articles which may be made of such material.

Dated Oct. 15, 1862.

2777. W. Wilson, 18a, Wigmore-street. An improved oblong drawing room bagatelle and billiard table, with reversible top, and made in various shapes and sizes.

Dated Oct. 16, 1862.

2791. G. Berry, 19, Buttesland-street, Hoxton, gentleman. Improvements in locks.

Dated Oct. 25, 1862.

2874. G. T. Key, Lieutenant in her Majesty's Royal Navy, Portsmouth. Improvements in fog and other signals.

Dated Oct. 27, 1862.

2893. G. Lindemann, Salford, engineer. Improvements in the manufacture of bricks, tiles, slabs, and other articles of earthenware or other plastic material, and in the machinery or apparatus connected therewith.

Dated Oct. 31, 1862.

2947. H. Williams and J. Maxton, Broadway, Nottingham, lace manufacturers. Improvements in machinery or apparatus employed in the manufacture of lace or trimmings made on bobbin net or twist lace machines.

Dated Nov. 3, 1862.

2969. W. Clark, 53, Chancery-lane, engineer. Improvements in castors, and in the manufacture of the same. (A communication.)

Dated Nov. 19, 1862.

3105. J. Chalmers, 8, Knight's-place, Vauxhall. Improvements in the use, combination, and application of iron and timber as armour for vessels of war and fortifications.

Dated Nov. 24, 1862.

3151. R. and W. Hawthorn, engineers. Improvements in pump valves.

Dated Nov. 27, 1862.

3176. J. Halford, Great Barr, Stafford, coke burner. Improvements in the preparation and treatment of small coal or slack, whereby a certain carbonaceous product is obtained and rendered available for use in the manufacture of iron and steel in the processes of casting and moulding metals, and in the manufacture of paint and such like articles.

Dated Nov. 28, 1862.

3197. A. Dudgeon, 19, Cullum-street, City, steam ship furnisher. Improvements in packing for various parts of steam and other engines and machinery.

Dated Dec. 1, 1862.

3218. J. Coppard, Hoxton. An appliance or appliances for horse shoes, to produce the effect of what is termed roughing.

3223. B. Oldfield, Coventry, machinist. Improvements in looms.

Dated Dec. 4, 1862.

3249. H. Swan, Bishopsgate-street Without. Improvements in stereoscopic apparatus.

3251. R. D. Kay, Accrington, manufacturer of patent fabrics. Improvements in the manufacture or finishing of endless machine blankets, or endless lappings for printing purposes.

3253. F. D. Delf, Liverpool, chemist, and T. C. Gibson, Ramsey, gentleman. Improved means and apparatus, whereby petroleum and other oils and hydro-carbons can be safely carried and stored.

3255. H. Castelbon, 15, Passage des Petites Ecuries, Paris. An improved press to be used in the manufacture of tiles and bricks. (A communication).

3257. J. Biggs, J. Johnson, T. Richardson, and T. Arnold, Leicester. Improvements in the manufacture of warp fabrics.

3259. R. Hornsby, jun., Spittlegate Iron Works, Grantham. Improvements in apparatus for cutting and pulping turnips and other vegetables.

Dated Dec. 5, 1862.

3261. M. Tildesley, Willenhall, Stafford, lock manufacturer, and E. Sharpe, Swadlincote, Derby, earthenware manufacturer. Improvements in the manufacture of earthenware knobs, and in fixing them in spindles used with certain kinds of knobs, in securing the metal mounts upon such knobs, and in apparatus to be employed in certain parts of this manufacture.

3262. L. Christoph, Paris, W. Hawksworth, Linlithgow, North Britain, steel manufacturer, and G. P. Harding, Paris, merchant. Improvements in drilling, drawing, and rolling metals, and in the machinery or apparatus employed therein.

3263. E. B. Wilson, Parliament-street, Westminster, engineer. Improvements in railway wheels, and in the mode of manufacturing the same.

3265. J. M. Rigby, Manchester, engineer. Improvements in presses for pressing cotton or other fibrous materials.

3267. W. J. Smith, Brooklands Cottage, Sale, Chester. Improvements in the manufacture of collars, cuffs, and wristbands.

3269. C. Galleti and F. Stefano, Charles street, Hoxton, cabinet makers. Improvements in articles of furniture.

Dated Dec. 6, 1862.

3271. R. Thorp, Liverpool, engine-tender. Improved coating or covering for steam boilers and other surfaces to prevent the radiation of heat.

3273. G. Wright, Friern Manor, Peckham Rye, farmer and cattle-food manufacturer. Certain improvements in the preparation and manufacture of food for cattle.

3275. J. Campbell, Belfast, flax spinner. Improvements in means or apparatus for heckling or hackling flax and other fibres.

3277. E. and W. Ullmer, Castle-street, printing machine manufacturers. Improvements in cylinder printing machines.

3281. W. Palliser, Captain, 18th Hussars, Dublin. Improvements in screw-bolts.

Dated Dec. 8, 1862.

3282. G. Lowry, Salford, machinist. Improvements in machinery for hackling flax, and preparing to be spun flax, hemp, tow, and such like materials.

3283. J. L. Budden, Fenchurch-street, merchant. Improvements in means or apparatus for obtaining and applying motive power for propelling or other purposes. (A communication.)

3284. J. Sellars, Pendlebury, near Manchester, manufacturing chemist. Improvements in the manufacture of pulp or half stuff used in the manufacture of paper, pasteboard, and similar articles.

3285. P. Todd, Wheelton, Lancashire, spinner and manufacturer. Certain improvements in pickers used in looms for weaving.

3287. G. A. Huddart, Brynkir, Carnarvon, gentleman. Improvements in buttons.

3289. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in preserving animal substances. (A communication.)

3293. J. A. and C. L. Kiesling, Liverpool, artists. Improved means of renewing worn out and partially worn out files and rasps.

3294. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the construction of steam generators. (A communication.)

Dated Dec. 9, 1862.

3295. T. Wingate, jun., engineer and iron ship builder, Glasgow. Improvements in dredging machinery.

3297. M. F. Benton, 121, Percy-street, Bedford-square, merchant. Improvements in the manufacture of gunpowder. (A communication.)

3299. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in treating liquorice root to obtatn liquid and solid extracts therefrom. (A communication.)

3301. J. Howard, J. Bullough, and T. Clegg, Accrington. Improvements in machinery or apparatus for preparing cotton or other fibrous materials to be spun.

3303. P. Effertz, Manchester, engineer. Improvements in machinery or apparatus for making bricks, tiles, drain pipes, and other similar articles.

3305. E. B. Wilson, 5, Parliament-street, Westminster, civil engineer. Improvements in machinery or apparatus for rolling metals.

Dated Dec. 10, 1862.

3306. J. Lamb, Holborn Paper Mills, Newcastle-under-Lyne, Stafford. Improvements in the manufacture of tissue paper for transferring patterns and designs.

3307. W. Inglis, Montreal, Canada, engineer. Improvements in steam boilers.

3309. J. R. C. Taunton, Birmingham, manufacturer. Improvements in the manufacture and ornamentation of metallic bedsteads, and other articles of like manufacture.

3311. M. Osborne, Birmingham, iron founder. Improvements in the manufacture of cast iron fenders.

3316. J. King, Heanor, Derby. Improvements in apparatus used for signalling on railways.

3317. E. Toynbee, Lincoln, analytical chemist. Improvements in extracting oils and fatty matters from shoddy, or refuse wool, skins, or skin pieces, glue pieces, cotton waste, and other animal or vegetable matter, and in producing an artifical manure.

Dated Dec. 11, 1862.

3319. W. Tristram, Halliwell, near Bolton-le-Moors, manufacturer, and H. Brereton, manager. Improvements in machinery or apparatus for sizing yarns and threads.

3321. R. A. Ronald, Glenpatrick, Renfrew, carpet manufacturer. Improvements in printing textile and felted fabrics, and in the machinery or apparatus to be used therein.

3323. A. W. Burgess, 107, Strand. Improvements in the preparation of anchovies.

3325. W. Goulding, 17, Margaret-street, Leicester. Improvements in ploughs.

Dated Dec. 12, 1862.

3327. G. Winiwarter, 32, King-street, Cheapside. Improvements in the construction of portable houses, walls, or partitions of buildings, strong rooms, safes, refrigerators, reservoirs, piers, and other structures: also applicable to the construction of casks and similar articles, boats, and ships.

3328. H. Sanderson, Sheffield, table knife maker. Improvements in the manufacture of table and other knives and forks.

3331. C. Hancock, West-street, Smithfield, and S. W. Silver, 4, Bishopgate-street, City, manufacturers. Certain compounds and substances applicable for electric insulation and other purposes.

3333. G. Clark, 30, Craven-street, Strand. Improvements in fortification for the defence of ships, batteries, and forts.

3334. S. Fox, Stockbridge Works, Deepcar, near Sheffield. Improvements in retorts and apparatus employed for the manufacture of gas, and also in purifying gas.

Dated Dec. 13, 1862.

3335. J. Brown, Atlas Steel Spring and Iron Works, Sheffield. Improvements in the manufacture of armour plates.

3336. J. W. Baker, Bury, cotton spinner. Improvements in machinery or apparatus for spinning cotton and other fibrous materials.

3337. J. Brown, 23, Sidney-street, Commercial-road East, engineer. Improvements in hydraulic machinery.

3338. E. Thorold, Lee. Improvements in drill braces, which improvements are also applicable to spanners.

3339. C. Corbet, 69, Upper Gardiner-street, Dublin, esquire. Improvements in rails for railways, and in the mode of forming the joints of the same.

3340. R. Aitken, Cambridge-street, Pimlico, civil engineer. Improvements in locomotive engines.

3341. J. Petrie, jun., Rochdale, ironmonger. Improvements in machinery or apparatus for washing wool and other fibrous materials.

3342. J. J. Thompson, Manchester, warehouseman. Improvements in machinery or apparatus for making pies and for cutting meat for the same.

3343. W. E. Newton, 66, Chancery-lane, civil engineer. An improved mode of, and apparatus for, repairing the rails, points, switches, and other parts of the permanent way of railways. (A communication.)

3344. M. Henry, 84, Fleet-street. Improvements in fitting or applying propellers to ships and other vessels. (A communication.)

Dated Dec. 15, 1862.

3346. W. Bestwick, Manchester, small-ware and braid manufacturer. Improvements in braiding machines.

3347. R. Stansfield, iron founder and machinist, and J. Dodgeon, mechanic, Todmorden, Lancaster. Improvements in looms for weaving.

3348. G. Buchanan, Bucklersbury. Improvements in machinery used in crushing sugar canes.

3349. W. Phelps, Nottingham, manager. Improvements in locks.

3351. E. B. Wilson, 5, Parliament-street, engineer. Improvements in machinery or apparatus for rolling metals.

3352. R. Kirk, Glasgow, North Britain, contractor. Improvements in machinery or apparatus for checking or stopping the motion of railway carriages.

Dated Dec. 16, 1862.

3353. J. McInnes, Liverpool, and E. F. Prentiss, Birkenhead. Improvements in the distillation and treatment of petroleum and other like oils to obtain products therefrom, and in the apparatus to be used therefore, parts of which can be applied for distilling other liquids.

3355. G. C. Warden, Islington, manufacturer. Improvements in ornamenting textile fabrics, leather, and other surfaces, in a cement employed therein, which is also applicable to the waterproofing of fabrics and materials, and in apparatus for applying and spreading such waterproofing cement. (A communication.)

3356. J. S. and S. Hancock, cutlers. Improvements in "anti-garotte" knives.

3359. W. and A. Smedley, Nottingham, tatting and lace manufacturers. Improvements in machinery or apparatus for the manufacture of textile or looped fabrics on warp lace machines.

3360. W. Hudson, Burnley, gentleman, H. Moore, cotton spinner, C. Catlow, overlooker, and S. Newburey, manager. Improvements in looms for weaving, and in arranging the warps therein.

3361. J. L. W. Thudichum, Kensington, doctor of medicine. Improvements in collecting human excreta, and in the apparatus and means employed therein.

3362. G. C. Wallich, M.D., retired list H.M.I. army, 17, Campden-hill-road, Kensington. Improvements in apparatus to be used in deep sea sounding for ascertaining the pressure and for raising specimens of the water.

Dated Dec. 17, 1862.

3365. R. Hattersley, Manchester, engineer. Improvements in apparatus for classing printers' types for composing machines.

3366. W. Tongue, Bradford, engineer. Improvements in machinery and processes for preparing fibrous materials.

3367. A. Albini, Birmingham, captain in the Italian navy. Improvements in breech-loading firearms.

3368. C. Defries, Houndsditch, manufacturer. Improvements in the manufacture or construction of lamps.

3369. T. Knowles, Ashton-nnder-Lyne, overlooker. Certain improvements in machinery or apparatus to be employed in preparing and spinning cotton and other fibrous substances.

3370. J. R. Hampson, Manchester, maker-up and packer. Certain improvements in the method of securing the extremities of the hoops or bands employed in packing bales, and in apparatus connected therewith.

3371. J. Thorne, Cardington-street, Hampstead-road. Improvements in apparatus for regulating the flow of gas to burners.

3372. J. Ramsbottom and G. Hacking, Accrington, machinists. Improvements in machinery or apparatus for measuring and registering the flow of water and other fluids.

3373. J. W. Hadwen, Kebroyd Mills, near Halifax, cotton spinner and manufacturer. Improvements in machinery or apparatus for spinning, twisting, and doubling cotton and other fibrous materials.

3377. R. Wheeler, High Wycombe, Buckingham, brewer. Improvements in ploughs.

3378. H. Burton, Princes-terrace, Prince of Wales-road, Kentish-town. Improvements in castors for furniture and other purposes.

3379. G. A. Huddart, Brynkir, Carnarvon, gentleman. Improvements in buttons.

3380. W. Clark, 53, Chancery-lane, engineer. Improvements in holders for lamps, candles, and other lights. (A communication.)

3381. C. J. L. Leffler, Gefle, Sweden. Improvements in constructing armour for ships and fortifications.

Dated Dec. 18, 1862.

3384. J. Clayton, Wolverhampton, furnace builder. Improvements in reverberatory furnaces for heating large masses of iron and steel, and in economizing the waste heat of the said furnaces.

3386. G. Russell, Glasgow, engineer. Improvements in cranes.

3388. J. and A. Brierley, Spa Mill, near Huddersfield, manufacturers. Improvements in carding engines.

3394. I. Holden, Bradford, machine wool comber. Improvements in means or apparatus employed in preparing and combing wool and other fibres.

3396. J. L. W. Thudichum, Kensington, Doctor of Medicine. Improvements in the preservation of beer and other fermented liquids, and in the apparatus and means to be employed therein.

INVENTIONS PROTECTED FOR SIX MONTHS BY A COMPLETE SPECIFICATION.

Dated Dec. 18, 1862.

3383. E. Lepainteur, Paris, manufacturer. Improvements in the fabrication of a salt for dyeing textile materials.

Dated Dec. 22, 1862.

3415. G. E. M. Gérard, Paris, manufacturer. Improvements in the fabrication of threads from vulcanized india-rubber, and the apparatus connected therewith.

Dated Dec. 23, 1862.

3422. F. Parker, Cambridge, carriage builder. Improvements in carriages.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

2281. J. Irvine and J. W. Hand. Rifle rest.

2296. W. B. Herapath. Treating crystallizable sugar.

2302. T. F. Kirby. Garments.

2315. J. T. Oakley. Heating stoves.

2326. J. G. Tongue. Processes and apparatus for extracting the natural wax or fatty matters from wool, hair, or other animal or vegetable substances. (A communication.)

2329. H. Whittaker. Healds or heddles.

2334. S. J. Paris and W. Bate. Alphabetical electric telegraphs.

2335. J. C. Schemmann. Manufacture of steel.

2338. T. Clements, P. Llewellin, and J. W. James. Lubricating various parts of steam engines.

2341. S. F. Griffin. Distillation of petroleum, or any oleaginous, resinous, or alcoholic bodies.

2348. H. Twelvetrees. Washing powders.

2352. W. Carwood, W. Boaz, and C. Colwell. Propellers.

2360. W. E. Newton. Treating fermentable substances. (A communication.)

2365. G. Davies. Machines for washing skeins of cotton, linen, wool, or silk. (A communication.)

2370. A. Crichton. Weaving ornamental fabrics.

2371. G. Davies. Singeing woven fabrics. (A communication.

2375. W. H. Turner. Carding fibrous materials.

2379. R. A. Brooman. Separating or sorting and washing minerals. (A communication.)

2421. W. Clark. Obtaining light and heat. (A communication.)

2423. J. H. Johnson. Regulating or controlling the working of motive power engines. (A communication.)

2446. W. Clark. Colouring matter. (A communication.)

2455. J. S. Margetson. Manufacture of the material intended for scarfs or cravats.

2465. J. H. Johnson. Firearms and projectiles. (A communication.)

2476. A. J. Alderman. Ships' windlasses, capstans, and cable stoppers.

2486. M. Smith. Raising the nap on woven fabrics. (A communication.)

2491. G. Ritchie. Extracting the liquid portion of yeast, spent hops, or other similar matters.

2502. W. Clark. Cigar and cigarette cases. (A communication.)

2559. W. and J. Todd. Machinery or apparatus for collecting waste or fly from spinning machinery.

2609. W. Upfill and W. Ashbury. Metallic bedsteads.

2829. W. H. Tucker. Self-closing apparatus for doors.

3115. J. Jewsbury. Machines for raising weights.

3196. J. Adams and W. C. White. Boiling and evaporating.

3209. J. Anderson. Tyres of railway wheels, and rails, switches, and crossings of railways.

3259. R. Hornsby, jun. Cutting and pulping vegetables.

3276. J. Birchall and E. Borrows. Propellers.

3282. G. Lowry. Hackling flax, and preparing to be spun flax, hemp, and tow.

3323. A. W. Burgess. Preparation of anchovies.

3331. C. Hancock and S. W. Silver. Compounds and substances applicable for electric insulation.

3337. J. Brown. Hydraulic machinery.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed December 30, 1862.

1915. E. F. Prentiss.
1917. R. A. Brooman.
1918. C. Lungley.
1919. G. H. Birkbeck.
1920. J. Greenhalgh and J. Greenhalgh.
1926. J. James.
1929. T. L. Atkinson.
1930. G. H. Hulskamp.
1931. J. Murray.
1933. J. Crisp and J. W. Elliott.
1935. G. Bedson.
1936. J. M. Hetherington and T. Jackson.
1942. T. O. Dixon.
1945. W. J. Cunningham.
1946. A. Drevelle.
1948. J. Howard and J. Bullough.
1950. R. A. Brooman.
1952. C. G. Hill and W. Jackson.
1953. A. Warner
1954. P. B. O'Neill.
1960. W. Spence.
1985. H. Kellogg.
2002. C. E. and J. Green.
2147. A. Boyle and T. Warwick.
2209. M. A F. Mennons.
2316. W. E. Newton.
2536. E. Astel.
2612. M. A. F. Mennons.
2876. J. A. Nicholson.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2920. G. F. Stidolph.
2953. X. C. and A. C. De Nabat.
2932. J. Giles.
2936. D. Hulett and G. Boccius.
2992. H. Cochrane.
2990. J. Whitworth.
2958. A. McDougall.
2967. S. King.
2969. J. S. Crosland.

1856.

90. A. C. Twentyman.
96. J. Goddard.

PATENT ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2925. C. May and E. A. Cowper.
2950. T. Holmes.
2938. G. Chisholm.

1856.

117. J. Hamilton.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to M. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of his good faith.

RECEIVED.—J. N. and M. and W. (engaged), C. R. E., B. H. and Sons, "Ignoramus," "Galvani," C. A., B. N., J. J. L., L. Bros., C. D., R. H. and Co., J. H., W. R., T. W. S.

A. T.—No.

A CONSTANT SUBSCRIBER.—See notice at the head of this column.

L. S.—We go to press on Friday morning. Your parcel came too late to be availed of.

F. P.—You would do best to advertise.

T. C. (Leeds). The degree of LL.D. was, we believe, conferred on Mr. William Fairbairn, of Manchester, by the University of Cambridge. The two L's mean the two laws; viz., civil and ecclesiastical.

T. M. (Bolton).—It has been noticed before that a condensing engine has generally a worse vacuum in winter than in summer. At first sight the contrary would be expected, but the air is more *dense* during cold weather.

Fredk. SMITH (Manchester).—Captain Scott's system of rifling consists of three deep grooves, somewhat like the French "cannon range," but of a simpler shape, the incisions being taken more gradually. It has a twist of one-fortieth. It gave great accuracy of range. This gun, when tried in 1861, at Shoeburyness, burst after about 300 rounds.

THE

MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 9, 1863.

GUNS AND PROJECTILES.

It is to be regretted that in discussing the merits of different systems of guns and projectiles, a narrow spirit of partizanship too often prevails. In the reports of experiments, the essays of professional artillerists, the opinions published in periodicals, and even in the transactions of scientific societies, the preference of one system in opposition to all others, is unmistakeably betrayed by writers and speakers. A particular kind of gun or shot is extolled as the *ne plus ultra*, or a principle is advocated as the indispensable condition of success. The muzzle-loader and the breech-loader, the smooth bore and the rifled, the solid and the built up, the coil and the shrunk-ring, the cast iron, the homogeneous, and the steel, with endless varieties of rifling, and this or that mode of strengthening one or the other part, and the form and material of projectiles—are by turns made out to be essential requisites, just as it suits the interest of the particular inventor or gun-maker, whose system it is sought to recommend to public favour.

Hence it arises that notices of ordnance experiments, and the conclusions drawn from them, are, for the most part, covert puffs of a favourite system, or indirect attacks on its rivals. The cause of this objectionable personality of competition, which disregards the real merit of a plan, and degrades the contests of artillerists to the greed of gain and diplomatic manœuvring for profitable contracts, is, in a great measure, to be attributed to the notorious Armstrong monopoly, which so long excluded every competitor, whatever might be the value of his system, from even a chance of a trial. A bitter feeling was engendered in the minds of inventors, a strong opposition was organized, and, at last, became so powerful in behalf of an engineer of acknowledged talent —Mr. Whitworth—that Government found itself compelled to allow him the opportunity of fair competition. But even this concession is accorded as a favour, and the avenues to the honours and benefits of Shoeburyness experiments, at the public expense, are jealously guarded by official authority.

Public attention is now fixed on two candidates for ordnance favour and emoluments. Between them a great duel of target practice will be fought, whilst the systems of other artillerists, superior, perhaps, to the Armstrong or Whitworth, will, for a time, remain untried (officially), and unappreciated because untried. But let us be thankful for the success of the Whitworth diplomacy. The barrier of exclusive patronage is broken down, and much credit is due to him, if, as we are assured, he has resisted the blandishments of power and refused a coalition, which would have secured a new lease of monopoly to the Ellswick combination, of which he might have shared the profits. The chief instrument for upholding that lucrative speculation was the *Times*, which suggested that the talented engineer might find it to his advantage to combine with the titled artillerist. For some weeks past, however, the leading journal has refrained from its extravagant praises of the Armstrong guns, having seen its statements of their transcendant merits disproved by the results of experiments, in which they were surpassed by other guns in power, range, accuracy, and durability. We hope the official organ has ceased the unscrupulous partizanship, which was as discreditable to itself as to the departments by which it was inspired. We trust some of our contemporaries will take warning from the *Times*, and not allow their columns to be the vehicle of promoting personal objects, by recommending any system of artillery on any ground but its intrinsic merit. The discovery of the best service gun is of such vast national importance, that personal considerations ought not to be taken into account in submitting any system to trial, or in reporting the results.

Mr. Whitworth's exploit of penetrating armour-plates with explosive shell has excited much commotion, not unmixed with jealousy, in the scientific mind. The potency of the damaging effect is systematically underrated; the holes perforated in the iron may, it has been said, be easily plugged, and it is questioned whether the guns, however strengthened, will stand the strain of the heavy charges which must, it is alleged, be used to obtain the high velocities indispensable to perforate the plates. In this manner is a decidedly new and great discovery, on its being ushered into the world in a practical form, assailed by theoretical writers. Any merit for originality of invention is denied to the man, who has actually accomplished what others have been talking or dreaming about, without it would seem the capacity to carry out their own ideas. As well might the credit due to Watt, as the inventor of the steam-engine, which he practically was, be disputed, because the expansive force of steam was known, and some crude attempts at applying it to machinery were made before his time. With strange inconsistency, a scientific artillerist, criticizing the performance of the Whitworth shell, admits the fact that its success is due to "the thorough and accurate manner, in which, as a mechanical engineer, he has carried out the plan;" and then "confesses to a strong feeling of indignation to find all of the patient investigation, and careful statement of principles by others, virtually appropriated by a *working* engineer." This sneering allusion to a man, who is no less remarkable for his inborn genius, in the application of mechanics, than as a *thorough* practical, as well as a first rate working engineer, is, to say the least, in bad taste.

We are led to make these remarks, because a series of important trials of guns and projectiles will soon take place; and in our desire to obtain fair play for all, by not limiting the Government experiments to a select and favoured few, we bespeak the candid judgment of those who may take a part or feel an interest in the approaching trials; and we will set the example by an impartial survey of the principal systems which are entitled to be tested at the public expense.

What are the essential requisites of a serviceable gun? What are the means of attaining them? To the first of these questions we reply: accuracy of aim, with maximum range and velocity. The answer to the second question is the subject we propose to take into consideration.

We will not attempt to offer an opinion on the various modes of constructing guns. We should involve ourselves and our readers in a labyrinth from which we perceive no issue. So many and so different in one sense, and so similar in another, are the systems of rival gun-makers, that it would be a hard, and, after all, a useless task, to evoke order out of such discordant elements. The plans of so-called inventors of ordnance differ in details of construction, but in the main features they are alike; and so much is this the case, that there is not a single one of the number who does not accuse some other one of imitation, or assert that what is claimed as a new invention has long been known and practised. The fact is, that all conceivable plans of construction have one object in view, which is, to make the gun of sufficient strength to do its work. This result, we believe, may be attained in different ways, depending partly on construction, partly on material—two points which, in combination, are susceptible of many modifications, the description of which would be tedious and impossible within our limits.

We assume that a gun must possess the required strength, without which it is no gun at all; but what is meant by strength in a piece of ordnance—that is, resistance to bursting—often depends more upon some peculiarity in the bore, or the powder or air-chamber, or the projectile, or the mode of loading and firing, than on the solidity of the gun itself. Again, the strength must be proportioned to the charge to be fired—that is a normal condition. In every point of view, it will be found that this estimate of the question of strength is correct. In considering the merit of any system of steam-engine, it would be just as reasonable to enter into a discussion on the necessity of a boiler being strong enough to resist the pressure of steam, as it would be to insist upon the necessity of making a gun strong enough not to burst, which seems to absorb the attention of some of our contemporaries, as well as of competing gun-makers. As we have said, there are many modes of accomplishing that *sine qua non* condition, the most efficient of which we will not pretend to determine.

Accuracy of aim and maximum range, and velocity, irrespective of the powder charge, depend upon rifling and windage. We leave ordinary smooth bores to their original simplicity. Their character is defined and well known, and cannot be changed without placing them in another category. The essential requisites we have referred to can only be attained by rifling, which regulates and determines windage, whilst it materially influences the strain upon the gun. Hence the whole question is narrowed into the enquiry, "Which is the best mode of rifling?"

Although, nominally, the modes of rifling made known to the world are multitudinous, they may be classed under a limited number of systems, and by defining these we shall avoid confusion, and make our observations more intelligible than by pursuing the details of slight variations in form, size, depth, and number of grooves and pitch of the spiral curve, for all of which innumerable patents have been taken out, without any one of them being the right thing.

For simplicity and distinctness, we range all the known plans of rifling under five heads, corresponding to the methods of five well known gun-makers or inventors, with whose names the public are familiar. We mean Armstrong, Blakely,* Whitworth, Lancaster, and Lynall Thomas.

For convenience of reference we mention these names, but, in point of fact, other artillerists, as Scott, Hadden, Britten, and other British and foreign manufacturers or inventors, have adopted or proposed plans on principles analagous to some one or other of those systems, with the sole exception of the oval bore, which, from its nature, does not admit of colourable imitation like the others. We thus present five different types, and we think we can show that in their distinctive characteristics they comprise all the modes of rifling, which, up to this time, have been conceived. We leave rival inventors to assert their claims to originality; our object is to clear away some of the confused ideas on rifling, and explain the principles on which the methods in practice are based.

---

* The Blakely guns, which have been manufactured and used in actual warfare to a great extent are, we believe, all smooth bores; but those exhibited at the South Kensington Palace were rifled on Commander Scott's plan, which, in the opinion of practical artillerists, is one of considerable merit.

The five systems we will designate—1. The narrow linear. 2. The broad deep groove. 3. The polygonal. 4. The oval bore. 5. The ribbed bore.

The first system is made available as rifling by the compression of soft metal forming the coating of the projectile. It is employed in the Armstrong breech-loader, and is said to be borrowed from Wahrendorff. The second is applied in the Armstrong shunt, and in the Blakely, Mersey, and other deep-groove rifled guns, which were exhibited at the International Exhibition. The third is the Whitworth plan, and has been termed the mechanical fit; but experience has already determined that, however desirable that peculiar feature may be, it cannot be maintained in practice. The fourth is Mr. Lancaster's invention, which strictly is not rifling, but a modification in the cylindrical bore, which produces spiral motion without rifling. The fifth is Mr. Lynall Thomas's system, which reverses the ordinary mode of rifling by forming spiral ribs in relief on the bore instead of cutting grooves into it.

The narrow linear method, in the proper sense of the term, is not a system of rifling *per se*. It is a medium for preventing windage and giving rotary motion to the projectile by covering it with a coating of soft metal, which, by compression, is forced into the narrow grooves. It is a *succedaneum*, not sound in principle, but empirical. The introduction of the soft metal is an obstacle, and, in one shape or another, produces difficulties which hitherto have not been, and probably will not be, overcome. The stripping off of the soft metal, its tendency to fill up the narrow grooves, and the varying strain on the gun in compressing the soft metal, are recognized as difficulties, some of which, to say nothing of their tendency to burst the gun, we can state from our own knowledge, not unfrequently drive the gunners to despair, and compel them to cease firing. To these defects is to be added the galvanic action of the lead or zinc on the iron of the projectiles, when these are kept in store any length of time. These palpable objections are of so serious a character, and, as we believe, irremediable, that there can be little doubt the "narrow linear" will ultimately be abandoned by the English, as it has been, after trial and mature deliberation, by several foreign Governments. The broad, or deep groove system, is exemplified in the Armstrong shunt, the Scott and Hadden, the Horsfall, and many other guns. We cannot perceive a difference of principle in any of these. The cut of the groove varies in form, and presents sections differing to the eye, but having, all of them, one of two characteristics—a loose fit to facilitate loading, and consequently causing an unavoidable amount of windage, or a close fit, causing a dangerous amount of friction and strain on the gun. To this latter action is to be attributed the bursting of heavy rifled guns, which is of such frequent occurrence. Some inventors, as a remedial measure, have tried soft metal ribs on the projectile; but the tendency to stripping and filling the grooves, as is in the case of the narrow linear, renders this method objectionable.

The mechanical fit, which promised so much, has not stood the test of actual practice. Every gun manufactured by Mr. Whitworth, strictly on that principle, has, it is said, burst after a not very long or severe ordeal; and although he demonstrated the precise accuracy resulting from a rigid adhesion to the "close fit," he virtually admits it cannot be carried out in practice, by the modifications he has introduced in his recently-constructed guns. Space, for the present, forbids our saying more with reference to this change than to point out that the mechanical fit, being abandoned, the Whitworth rifling ceases to be a system of itself, and comes under No. 2 of our classification.

The oval bore is not so much a system of rifling as a *quasi* smooth bore, slightly diverging from the circular, and thus effecting the object of rifling. The rotary motion is imparted to the projectile by its passage through an easy spiral channel, gradually rounded off from the circular circumference of the bore, which cannot properly be termed a groove, although it fulfils the functions of a groove. This method we regard as a move in the right direction; it is free from objections incident to the three first systems, but its action, in respect of windage and accuracy, is, at present, so undetermined that, we believe, Mr. Lancaster himself will admit that the "oval bore" principle, so far as can be judged from his attempts up to this time, requires mechanical modifications before it can be said to supply the essential requisite of a good service gun.

The "ribbed bore" has to be tested before its character can be determined. On a cursory view, Mr. Lynall Thomas's method might be thought similar in principle to Commander Scott's; but there is a distinctive difference. The latter is an angulated groove, cut into the bore; the former is a rib in relief, the groove being in the shot—a plan which entitles it to be treated as a distinct system.

A large gun on this principle is under construction at Woolwich, and will, we understand, be soon submitted to trial. In the meantime, we may offer some obvious remarks. Here we have ribs projecting from the surface of the bore, as guides, over which the grooves in the projectile run. If the bottom of the groove presses too closely on the top of the rib, the strain on the gun will be great; and being limited to the line of the rib, and not spread over the face of the bore, will the more tend to burst the gun. If the rib be so shallow, or the groove so deep, that the two come in contact only at their sides, the pressure of the shot will be against the cylinder of the bore, just as in the case of an ordinary smooth bore, with the same amount of windage. It would not be safe to allow less windage, as the pressure and friction on the sides of the ribs would alone be a cause of obstruction and of strain on the gun, which it would not be safe to augment. This lateral pressure on the ribs is the danger to be guarded against. It is to be feared that the continuous rubbing against the side of the grooves will gradually, especially if steel shot be used, wear away the rib, and tend to destroy the gun. This action (the cutting of the shot into the rib) is likely to be more damaging than the action of a shot rib on a rifled groove.

Accuracy of aim and velocity are, more or less, dependant on rifling. The former, it may be said, absolutely—the latter, contingently; the powder charge here being the main cause. The perfection of rifling would be a method which combined the mechanical fit, and consequently the absence of windage, with such a degree of resistance, as should offer no difficulties in loading, if a muzzle-loader, and no dangerous strain in firing. In these two essential conditions the three first systems are proved, by experiment, to be deficient Unless some improvement is made in the "oval bore," we may say it is in the same predicament. The "ribbed bore" remains to be tried.

In order to form a right conception of the action of a rifled projectile in a gun, from the moment it is set in motion by the explosive force of the charge, to its exit from the muzzle, we must consider the path it follows, and the friction it exercises on the rifled grooves, or ribs. These effects obviously are determined by the nature of the rifling, which, it may be said, overrides the whole question, and is, therefore, the real point to be considered. So vague and unsatisfactory, however, are the notions prevalent on rifling—so opposite to each other in principle are the systems and opinions of rival gun-makers and artillerists—that evidently the art of rifling is not yet understood, much less is it practised in accordance with scientific data, which admit of mathematical demonstration. Nothing is true which cannot be demonstrated.

It is not without utility to direct attention, as we have done, to some of the well-known modes of rifling, with the view of enabling engineers to form correct notions on the actual requirements of a good system. On this interesting subject we will take an early opportunity of offering some remarks.

We should not do justice to the ablest scientific writer on gunnery, Mr. Robert Mallet, C.E., F.R.S., if we did not acknowledge that we are indebted to his admirable essay on Artillery, exhibited at the International Exhibition, for some of the technical data above referred to; but we hold ourselves responsible for the conclusions we have drawn from them.

JOSEPH LOCKE.*

THE life histories of deceased engineers of note promise to afford an ever-renewing staple for the manufacture of biographies. There is a fascination in reading the true account of almost any man's life—a fascination stronger for most men and women than the dreamy blandishments of a novel. The biographical field is however, now-a-days, rather limited for the book-makers. Naval and military heroes have been fortunately rather scarce for the last thirty years. We have had no "thirty years'" war to furnish us with a fresh Gustavus Adolphus, or another Wallenstein. Interesting biographies could, no doubt, be written about many men belonging to the "learned professions," law, physic, and divinity. But it would be difficult to write a readable life of a physician or lawyer, without at the same time invading the secrets of private families. An engineer, however, may be said to deal with the secrets of nature and art. In modern, political, and social life, the educated masses are taking up the same position and power as the princes and nobles of former days. The modern engineer, with such a public for a patron, is playing the same part as the painter and architect of medieval Italy. Instead of erecting gorgeous cathedrals, or painting the frescoes of the Sixtine chapels, he builds Crystal Palaces for the multitude, and equalizes all conditions, by making the former luxuries of the few mere conveniences for the many. It is a trite remark that mechanical engineering is changing the whole aspect of life. The entire extent of its influence upon naval and military warfare, cannot as yet be determined. Rifled cannon and rifled small arms left their impress upon history at Magenta and Solferino. Colt's revolver keeps the Floridas against the Red man. The long range of the Armstrong gun helped to take us to Pekin; a city as fabulous to our ancestors as the realms of Prester John. In the words of Prince Albert, "Science and mechanical improvement have in these days changed the mere practice of cultivating the soil into an industrial pursuit." What mechanical invention can do in the arts of life is only beginning to be recognized in this century. Cardinal de Richelieu, when he imprisoned Solomon de Caus, the steam-engine projector, as a madman, forgot that insignificant and unknown mechanics had changed the world to a greater extent than all the statesmen and heroes since the days of Alexander. He forgot that gunpowder had struck down the feudalism to which he was giving the "*coup de grace.*" He forgot that the minute magnetic needle had discovered a world larger than the Roman empire. He forgot that Luther was but the natural sequence of Guttenberg; and he imprisoned the man who was offering him more power than was ever in the gift of a Cæsar.

---

* "The Life of Joseph Locke, Civil Engineer, M.P., F.R.S., &c. By Joseph Devey." London: Bentley.

Any one of our readers could no doubt multiply these instances of the extraordinary influences of mechanical science on modern life. It will be evident that the lives of industrial heroes must afford much material for picturesque treatment. Accordingly, such histories are becoming quite a branch of popular literature. Such works will, no doubt, stimulate ingenuous youths, like the lives of our old Admirals. Their influence will be felt in many ways. Instead of running off to sea, our rising generation will want to be engineers. Should a fond parent ever discover his boy scrawling on a slate the faintest resemblance to an engine, or should he be seen making a dirt pie with the least resemblance to a locomotive, the unfortunate boy in question will be immediately dubbed as a "mechanical genius." For the consideration of a hundred or so a year, after having been dosed with the usual quantum of Latin, he will be put with some noted engine maker, who will give him his first and last look when he takes the premium. After having played at working for three years or so, he will come to swell the ranks of a business as overcrowded as most others.

As soon, therefore, as an eminent engineer's body becomes, in the course of nature, food for worms, his life will be legitimate forage for writers.

The love of these latter gentlemen for their chosen subject, is said to exceed in intensity "even the love of woman." Small men will be made heroes of; their mistakes will be hidden or diminished, and their achievements looked at through a strong magnifying glass, tinted with "couleur de rose." Should we wish to get at the real truth, we shall have to read a series of these works, as reciprocative corrections of each other. This latter process, however, will be good for both authors and publishers.

We wish that Joseph Locke, who was an eminently honest, able, and energetic man, had been more fortunate in his biographer. We also wish that Mr. Devey had at least more science and taste, and a little less classical learning. In the words of Macaulay, "here and there a manly sentiment makes its appearance in company with Prometheus and Orpheus, Elysium and Acheron, the plaintive Philomel, the poppies of Morpheus, and all the other frippery, which, like a robe tossed by a proud beauty to her waiting woman, had long been contemptuously abandoned by genius to mediocrity." How Locke himself would have smiled if he had been told that he had constructed works "vaster far, and far more important" than the walls of Thebes, and that his undertaking of "carrying a railway across Shap Fell was perhaps as serious an undertaking as digging the trenches of Rome." Mr. Locke is successively compared to Alfred the Great, Cromwell, and to the Roman Curtius.

When a boy, Mr. Locke would not rock a baby's cradle; so he is compared to Alfred refusing to watch the Saxon house-wife's cakes. He intended, while in a youthfully despondent state, to emigrate to America. Forthwith Mr. Devey compares him to Cromwell. Having wept while thus desponding, Locke's biographer says: "There are some tears more potent even than those of Helen; and even from them sprang a plant, whose leaves cured the bite of serpents."

Trevethick, turning away from his locomotive to take up other schemes, is compared to "Attila turning away from Rome." No less personages than Venus and Æneas, Eolus, Neptune, Erinnys, and Polyphemus, are brought into the field. Mr. Devey has also explored the classical regions of Erebus and Arcadia, in search of apposite comparisons. We suppose that, in case Mr. Devey should ever write the biography, for instance, of Mr. Fowler, the steam-plough engineer, Mr. Fowler will be represented as celebrating the marriage of Ceres and Vulcan. It is a pity that this classical frippery should be jumbled up with much that is interesting and sensible. There are, however, other errors not merely errors of taste. In the course of our by no means very careful perusal of the volume, we have met with several curious passages, which make it evident that Mr. Devey is in a state of rather blissful ignorance as to scientific matters.

What is meant (p. 64) by a "*left-tenter*" to equalize steam pressure. (Page 72)—It is stated that Trevethick "took out a patent for *heating* the *surface* of the boiler by means of small tubes." We are informed (p. 118) that "steam, operating upon an imprisoned atmosphere, generated much carbonic acid gas!" What is meant by "*steam machines* (*sic*) *accompanied by a dagging apparatus?*" (p. 59).

Mr. Devey very sensibly begins the book by an account of his hero's ancestry. This is a point too often neglected by biographers. In the East, the doctrine of hereditary transmission has been practically recognized for ages. The Turks say that the father is known by the son, and the Chinese ennoble the ancestry, and not the descendants, of a distinguished man. We believe that in Franklin's autobiography that extraordinary man alludes to the fact of he himself being the exact counterpart, in mind and face, of his English grandfather. We consider that Locke's father, if Mr. Devey's account of him be true, would, with the same opportunities, have done as much as his own fortunate son. But, as Mr. Devey himself would say, "Where would Achilles be without a Homer?"

Joseph Locke, the son of William Locke, was born in the year 1805, on Attercliffe Common, near Sheffield. He was the youngest of four sons, a merry, mischievons, active lad, with plenty of "*amour propre*" in his mental composition. He was taken from the Barnsley Grammar-school when only 13, so that he owed his success in life more to "mother wit than school wit." According to the homely German proverb, an ounce of the former is worth a pound of the latter. On leaving school he was first placed with a Mr. Stobart, a coal viewer, and next with a young land surveyor. The self-love of the boy rebelled on its being required of him, that he should take Mr. Stobart's letter-bag to the post-office on his shoulders, and that the land surveyor should order him to rock the baby's cradle. He, therefore, wisely threw up both these situations. His father, William Locke, being now the manager of a colliery, employed Joseph "to 'lead' coals in a cart to houses in Barnsley." This the boy of fifteen felt as a degradation, and he meditated, like most active spirits at one time or another, emigration to America. It is easily seen by these trials that the motive power of Joseph Locke's character was a strongly developed *amour propre*. Towards the end of the year 1823, George Stephenson, who was an old acquaintance of the father, from having worked with him at Newburn, came to see his old friend, and took Joseph on as an apprentice in his Newcastle workshops. This was the tide that led Locke on to fortune. Henceforward, his biography is, to a great extent, the history of the iron roads built during the last thirty years.

While in the workshops at Newcastle, Locke "eschewed delights, and lived laborious days." He made up for the deficiences of his scanty education by studying of an evening, after the day's work. He was thus prepared, theoretically and practically, for the great railway campaigns that ensued after the famous locomotive trials in 1829, on the Manchester and Liverpool Railways. Locke first publicly distinguished himself by writing, in conjunction with Robert Stephenson, a pamphlet, entitled "Observations on the Comparative Merits of Locomotives and Fixed Engines, as Applied to Railways, being a Reply to the Report of Mr. James Walker;" Mr. Walker having advocated fixed, instead of locomotive engines, for working the Manchester and Liverpool line. This pamphlet determined the question in favour of the locomotive, but "George Stephenson had urged that the title-page should bear his name, and his name only." Locke refusing to concede this, a coldness was engendered between himself and his employer, that ultimately, fomented by other causes, led to a complete breach. Locke also discovered serious errors in the laying out of the tunnel which connected Edgehill with the station in Lime-street, on the Manchester and Liverpool line. These mistakes had been overlooked by Stephenson, and the results were increased confidence on the part of the directors, in Locke. "Hence, after the passing of the Grand Junction Bill, in 1833, when the appointments on the line came to be made, Locke was inclined to expect very much, and Stephenson was inclined to give very little."

The upshot of all this was that, in 1834, the now rivals were appointed joint engineers, and this not answering, Locke was appointed engineer-in-chief in August, 1835, on the retirement of George Stephenson from the joint management of the then Grand Junction Railway.

As far as we can understand Mr. Devey, he seems to claim for Mr. Locke the introduction of the double-headed rail, and the wooden key during his engagement on this line.

In 1833, Locke married the daughter of Mr. M'Creery, a printer, and the author of a poem called "The Press." The union seems to have been very congenial and affectionate, and invigorated by domestic happiness his mind was able to entirely concentrate itself on his great undertakings. On the resignation of Mr. Giles, Locke was appointed engineer of the line between London and Southampton. When this railway was about half completed, he was appointed engineer of the line between Sheffield and Manchester. On this work he achieved, at Woodhead, the great tunnel, perforated through what is "called the back-bone of England, being a portion of the central mountain line which divides the country."

His next line was the Preston and Lancaster, followed by the Lancaster and Carlisle. This latter railway had to encounter a rival project in Parliament for taking the Morecamb Bay route. Mr. Locke's first railway in Scotland was a line between Greenock, Paisley, and Glasgow. He laid out several other Scotch lines, amongst which was the Caledonian—another line that had a fierce battle in Parliament with a rival project. The only result was, that about half a million of money got squandered in Parliamentary expenses. Every traveller on a line thus highly favoured by Parliamentary supervision, has thereby to pay considerably more than would otherwise be exacted.

In France, Mr. Locke built the Paris and Rouen, the Rouen and Havre, and ultimately the Caen and Cherbourg lines. He also built the first Spanish railway, the line from Barcelona to Maltaro. This undertaking undoubtedly gave Spain the first impetus in the direction of modern progress. The Dutch-Rhenish Railway Company refused to take his advice against the adoption of the 6 ft. 6 in. gauge, and has thus isolated itself from the German lines, to the great impairing of the shareholders' dividends. He was the member in Parliament for Honiton from 1847 till his death, in 1860. With his usual concentration and common sense, he confined his Parliamentary duties to those subjects with which he was acquainted by practical experience. He greatly distinguished himself against the Sabbatarian bigotry that left the amiable Duchess of Sutherland weeping on the railway platform, while a seat in the mail train would have enabled the Duchess to close the eyes of her dying father. In the session of 1851 Mr. Locke introduced into the Commons the Railway Audit Bill which Lord Stanley had carried through the House of Lords during the preceding session. The bill, however, fell to the ground. He brought his experience acquired in the successful prosecution of great joint-stock undertakings to bear upon such subjects as the Thames Embankment, the Westminster Bridge, Dockyard Expenditure, the Ordnance Survey, the Netley Hospital job, &c. His weight—as a speaker—on these departments of public business was so far felt, that he was generally talked of as the successor to Sir Benjamin Hall as Commissioner of Public Works when the latter was elevated to the peerage. It was, however, probably thought that such a man as Locke was too combative for the lotus-eaters of official life.

In his latter days he took to field sports, and pursued his birds with the same energy he used to display towards scamping contractors. While thus enjoying himself on his moor in Scotland, he died after an illness of scarcely twelve hours, in September, 1860. He is buried in Kensal Green. Joseph Locke's character was of an essentially English stamp He was an incarnation of common sense, integrity, combative energy, and mediocrity. To use his own words, when President of the Institution of Civil Engineers—"The profitable effect of capital, directed to a given object in the hope of profit, is the main element of the subject in which the *modern* engineer has to exert his skill and judgment." This truth formed the keystone of his practice, and consequent success. The following is a passage worth quoting out of this book:—"The world is more indebted than is commonly supposed to people of average understanding. They originate no new ideas; they leave this task to genius. But they carry a good many of them out, when genius, whose own ideas they have already accepted, would prevent the acceptance of any others. The initiative in progress is taken by genius, but not less by it is taken the initiative in opposition to progress. It is no less true than fortunate, that a majority of those who could initiate nothing, invariably sides with the former. Were men of genius to unite their mental forces, we should probably soon reach the goal towards which progress points. But as their mental forces appear to be about equal and opposite, it requires a considerable preponderance of the inferior mental forces to act in the right direction for us to move forward at all." Locke first reduced the management of contractors to a system. "Crooked contractors found this out, to their utter discomfiture, and even straightforward contractors to their occasional loss." Accordingly, he was the best abused man in England amongst this class generally.

The chief feature of the more recent railway practice is the adoption of the cheaper system of steep inclines and sharp curves. This is more especially the case on the continent. In 1843 Mr. Locke was examined before the French Chambers with respect to the supposed danger of working an inclined plane of 1 in 110. The French engineers fixed the lowest point of safety at 1 in 200. Mr. Locke was allowed to adopt a descent of 1 in 125. Gradients of 1 in 50, or even 1 in 35, are not uncommon on the lines in Germany. Mr. Locke's common sense showed itself very conspicuously in the famous battle of the gauges in 1845. The pamphlet he published on the subject came too late to effect a cure, the evil being already accomplished. We may regret that a broader gauge than 4 ft. 8½ in. was not adopted from the first, but, under the circumstances, Mr. Locke's course in reference to this question was the true one to be adopted. There could not be a greater contrast between the brilliant transplanted Frenchman, Brunel, and Locke, the Northcountryman. A direct contrast as to personal qualities, engineering practice, and the results of that practice, Brunel would have done very well as the servant of a Louis XIV., but as a servant of shareholders he was a costly failure. Despots with their hands in the purse of a nation, want works of art at any cost: shareholders only want half-yearly dividends. An engineering *Punch* might make a very good cartoon, entitled, "Engineering à la Mode," by showing a section of the Thames with *M. I.* Brunel's tunnel, and *I. K.* Brunel's Great Eastern floating in the river above.

The monuments of both Locke and Brunel may be found in certain share-lists. The one monument is, however, a triumphant arch; the other is a gravestone to defunct hopes and burnt scrip.

This is, upon the whole, a very readable book, which is the main thing in a book, just as common sense is the main thing in engineering practice. A strongly marked portrait is given of Locke the engineer, though the picture is marked by many blotches, some of which we have pointed out. The summary of the railway events of the last thirty years is also compiled in an interesting manner. Mr. Devey has evidently written his book *con amore*, but this love of his subject has occasionally led him into exaggeration. Talleyrand's recommendation of "*surtout pas trop de zèle*" would not be unappropriate to a man undertaking a work of this kind. In case Mr. Devey should ever write another engineering biography, we hope that he will draw less of his inspirations from "Lemprière's Classical Dictionary," and more of his facts and terms from a good technical vocabulary.

II.

IRON CASED SHIP-BUILDING.—IRON CASED SHIPS.

The *Standard* of Tuesday last contains an article on the progress being made in building "The Enterprise," and "Favourite," under the superintendence of Mr. Reed, at Deptford. After some very complimentary remarks, the writer says:—

Before mentioning these two vessels more particularly, it will be well to observe that a peculiar concurrence of circumstances enabled, or rather forced, the Board of Admiralty to act in the way described in reference to Mr. Reed's proposals. In the first place, Lord Clarence Paget and his colleagues found themselves in a condition of utter helplessness, being fairly drowned by the tide of events which they were too weak to stem, and they were, therefore, ready to clutch at anything which held out the promise of a rescue. Few thanks for the promptness with which they acted. In the next place, the suggestions to which they gave their approval emanated from a person who could not well be resisted even under far more favourable circumstances. Mr. Reed was trained originally in the Admiralty service; he had gone through all the steps which are usually held indispensable to an Admiralty constructor; years before he had attained a high position as an authority on questions of naval construction; he had even been offered a seat in Parliament, expressly in order that the Government of the day might benefit by his advice and knowledge; he had secured a high position as a public writer on naval questions, articles in the *Cornhill Magazine* and other publications of influence, being known to proceed from him; he had been fixed upon by all the leading shipbuilders of the kingdom, public and private, as the most suitable person to found and lead the Institution of Naval Architects; and last, though not least, he was known to be—by virtue of his official connection with that institution, if not otherwise—on terms of confidence with the most active, enterprising, and influential naval reformer alive, Sir John Pakington. All these things rendered it impossible for an Admiralty which had no better secretary than Lord Clarence Paget to resist the opinions and wishes of Mr. Reed, and at the same time they enabled the board to accept his views with little or no regard to the traditions and prejudices of their own antiquated professional advisers. It may be true that Mr. Reed's name has not been thrust forward at trials of iron-cased ships, at Shoeburyness experiments and elsewhere, like the names of Scott Russell, Fairbairn, and others, who seem to think that nothing can prosper without their aid; but this was an advantage both to the board and to Mr. Reed, since it left his suggestions free to stand only upon their merits, while his long acquaintance with the ins and outs of things at Whitehall and in the Royal dockyards gave his words a degree of weight for which no show or pretension on the part of others could compensate. We will now turn to Mr. Reed's first vessel, the "Enterprise."

On visiting this ship one's first impressions are somewhat confused, owing to the utter unlikeness of the ship to anything before seen in this country. A high, square, solid-looking tower rising up from a low, shallow, sneaking-looking hull, after a fashion that one might stumble upon in America without astonishment, but that seems strangely different from everything to which one has been accustomed here. On examining the actual state of things, however, we soon find that the singular appearance of the ship is due only to the fact that we see her in an incomplete state, the iron upper works having yet to be erected. When these have been built up—and the workmen are now about to commence them—the tower will become embodied, so to speak, in the general form of the hull, and the "Enterprise" will very much resemble in external appearance an ordinary steam sloop. The form of her bow and stern will, however, be very unusual. The timber stem has been carried in a curved form below the water, in order to act as a ram, while the light iron upper works will recede from the water line, in order that they may not suffer when the blow of the stem is delivered. The stern, again, is entirely novel, having been designed and formed, we are glad to say, so as to avoid the serious and disgraceful blunder which has been committed in the "Royal Oak" and other ships of her class, and by which the rudder-head is exposed to the direct blow of the shot. The "Enterprise" is the first British ship of war which has had her stern or counter immersed sufficiently to protect the rudder-head thoroughly, and therefore the first that will be able to go into action with confidence in the preservation of her steering powers. For Mr. Reed has protected, not the rudder-head only, but the steering-tiller also, notwithstanding the increased difficulty of accomplishing this in a small ship. The plan will doubtless be carried out in every ship of war constructed hereafter, and Mr. Reed deserves credit for having set so excellent an example. In consequence of this depression of the counter the form of the ship abaft is, of course, made very unusual. In fact, the stern will "tumble home" in very much the same way as the bow, and will, in fact, look very much like it. The "Enterprise" has, at the same time, been made so strong and solid aft that she could probably deliver a blow with one end as well as with the other, and without damaging her steering gear, if the rudder itself is not too large to admit of that. Another cause of difference between the "Enterprise" and of other ships in the concentration of her armament. In the whole length of her side—180 ft.—she will show but two ports only, but out of them 110 pounder Armstrong guns will pour forth their tremendous missiles with a far more terrible effect than any number of the small guns that sloops usually carry can produce.

The armour of the "Enterprise" will consist of three separate masses, so to speak. First, there will be the belt going entirely ronnd the ship in the region of the water line, this belt being 4½ in. thick at the upper edge, and tapering off to 3 in. below. Next there will be the armour on the sides of the battery, rising from the belt up to the battery roof or deck. This will be 4½ in. thick from top to bottom. Lastly, there will be the armour upon the athwartship bulkheads, which protect the guns and gunners from a raking fire. This will be 4 in. thick above the upper deck, and 3 in. between decks. The upper deck will be of iron, covered with deck plank, except in the wake of the ports in the bulkheads just mentioned. These ports, taken in combination with other arrangements connected with them, constitute one of the most important features of this admirable ship, and, in fact, of Mr. Reed's system. The advantage gained is, that of being able to get an almost fore-and-aft fire at point-blank range, and a perfectly fore-and-aft fire with slight elevation from the centre of your ship. By keeping the upper iron deck of the "Enterprise" below the portsill of the battery, the designer is able to employ the whole of his four heavy guns in fore-and-aft firing —a result never before achieved even with the heavy pivot guns which have so long encumbered the bows and sterns of our men of war, causing them to pitch fearfully in a seaway, and straining them all to pieces continually. We doubt if any sloop or corvette of war will henceforth be built without having this provision made in her. The offensive and defensive powers of the "Enterprise" will undoubtedly be rendered most terrible by the facility with which she can bring her large guns to bear in all directions.

We have already spoken of the form of the ship above the water, which will be well adapted, as we have seen, for the work of actual service, and will not, we believe, be unsightly. Of the form of the bottom we speak with still greater praise. We believe the "Enterprise" to be the handsomest ship below the water that exists in any of the dockyards. The beauty of the lines arrests the eye of every visitor, and is a constant theme of admiration among naval men. We are given to understand that Admiral George Elliott, the newly appointed superintendent of Portsmouth Dockyard, and well known as one of the smartest and most enterprising officers in the service, expressed himself much pleased with the form of the "Enterprise" on the occasion of his visit to her a few days ago; and, as the captain of the "Phaeton" frigate in her palmy days, he must be extremely well qualified to judge of such a matter. In fact, there can scarcely be a doubt about the excellence of the "Enterprise" as a sea-going craft, for not only is her model beautiful, but her extremities will be so light and buoyant that she will doubtless float and turn about like a duck upon the water. The whole of her principal inboard weights, and nearly the whole of her armour, are concentrated in the middle of the ship, where there is the body of the ship to support them; while the ends will contain little or nothing but the officers and crew and their traps; and it is well known that nothing is so favourable to both sailing and steering as this collection of all the great weights at the centre of the ship. There is every reason to believe, therefore, that our first English iron-cased sloop will be not only capable of going to sea, but one of the handiest and easiest crafts under canvass in the service, with the light but efficient rig which has been devised for her.

The strength of the "Enterprise" has been a subject of some discussion in naval circles, but we believe a visit to the ship herself must set every one's doubts on that point at rest. In the wake of all the armour, including the encircling belt, the timber frame, though small in scantling, has been made solid everywhere by means of filling timbers, so that there is throughout a backing of at least 18 inches of solid timber to receive the armour, and in the vicinity of the water line the thickness of the solid wooden side must be at least two feet. As regards her strength in a seaway, that must be perfect in so far as the timber hull is concerned, because in addition to the features just mentioned, the transverse bulkheads, formed of 12-in. teak timber in two layers, bind the extremities of the battery together so firmly that it will be impossible, we think, for the sides to yield or strain even when the ship is rolling under the worst of circumstances. With regard to the iron upper works, there can be no reason why they should not be as strong as the upper works of any ordinary iron ship, while of the sufficiency of the connection between the timber hull and the iron the ship-building officers engaged upon the ship seem to enteriain no doubt at all. In fact, we believe the Board of Admiralty themselves, who are not very competent judges of mechanical matters, are probably the only persons who think it necessary to suspend their judgment upon this feature of the ship until after she has been tried at sea.

A very few words will suffice for the iron-cased corvette "Favourite," which is being built upon the next slip to the "Enterprise." The principal features of the two ships are alike, but the armour of the "Favourite" is to be carried up to the gun platform, which is to be continued right fore and aft in the ship, and is to form, in fact, the upper or spar deck. This will require a larger proportionate amount of armour than the "Enterprise" plan, but it will do away with the necessity for erecting upper works of iron, and it will render the "Favourite" a completely protected ship. Although a less light and handy craft than the "Enterprise," the "Favourite" will be a fine sea-going corvette, carrying eight of the largest guns, and yet of but little more than 2,000 tons. The misfortune is that she is having a good deal of unseasoned timber put into the stern portion of her frame, owing to the absence of a proper supply of seasoned material, and this will probably lead to some delay in her completion.

SCREW SHIPS OF WAR.

In 1844 the "Arrogant," by the advice of the late Lord Herbert, then secretary of the Admiralty, was laid down for a screw-frigate, with auxiliary power, as an answer to the menacing attitude of France, the increasing proportions of her steam navy, and the celebrated pamphlet of the Prince de Joinville. To the auxiliary-powered "Arrogant" succeeded full-powered frigates, "blockships" of evil renown, and magnificent liners, mounting from 90 to 130 guns, all propelled by the screw, and in some of the finest of the frigates and liners driven by engines of a thousand nominal horse-power, capable of working up to 4,000-horse at full pressure of steam. Next came the "iron" age, represented by the "Warrior," of 6,039 tons, and carrying but 40 guns behind her iron walls, her screw driven by engines of 1,250-horse power. We are now entering upon a new phase in the introduction of Capt. Coles's turret and Mr. J. E. Reed's central square tower systems, the former being applied to the "Royal Sovereign" and "Prince Albert," and the latter to the "Favourite" and "Enterprise." As we progressed through these different stages so has the cost of our ships increased. We still retain the screw as a means of propulsion, and we cover the lofty masts of each ship as we send her to sea with a mass of wood and cordage sufficient to foul and disable the screws of a whole fleet if knocked overboard in action or in a breeze. We have been engaged all these years in testing the powers of the screw, and have also learnt its great attendant, fault. A turn or two of a rope's end, and the screw becomes fixed, and the 14-knot ship, with her magnificent engines, becomes helpless on the water, as far as her machinery is concerned.

Since the commencement of the formation of our screw fleets by the launch of the "Arrogant," the thought ever dominant in the mind of the naval officer has been, How could a screw ship be rigged so as to lessen the danger of fouling the screw by falling spars and rigging or floating wreck? The question has, in the meantime, been often enough discussed by officers of the royal and mercantile marine, and by ship-builders and scientific men on shore. Some have contended for the retention of the ordinary three masts for a full-rigged ship, while others have advocated the addition of a fourth or even fifth mast for the longest ships. Some few have even gone so far as to argue that our iron-clads can never, under any circumstances, if clothed with armour all round, like the "Minotaur" will be, be made safe sea-going ships; and, as they will possess engine-power which they can use economically by a low pressure of steam, they ought to depend upon steam alone for their motive power. So far, all the disputants have agreed that the present form and description of masts, yards, and sails, must be made use of with three or four masts, or the ship must depend upon her steam power alone. There are, however, two existing modifications of rig and disposition of spars introduced by the Admiralty in the "Defence" and "Resistance." No one, however, could wish to see such specimens multiplied. With the usefulness of their Cunningham self-reefing topsail, marred by attaching it to a fixed Howe's (American) topsailyard, and their unsightly head and after-sail arrangements, they look everything that is ugly aloft in a seaman's eye, while they are perfectly inefficient under sail, as compared with the "Warrior" or "Black Prince."

The advent of the turret-ships has, however, led to plans being laid before the Admiralty for masting and rigging our sea-going iron-clad ships on an entirely novel principle, superseding altogether hempen rigging, cordage, and wooden masts, by iron tubing and chain, exactly as iron ships have superseded wooden ones for all future purposes of war. It is proposed in these plans to give the ship tripod tubular iron masts, the central, or foremost, of the three tubes being of sufficient length to act as lowermast and topmast, and without tops or cross-trees. A long wooden topgallantmast fidded abaft the topmast head would carry topgallantsails and royal. Topgallant and royal yards would be of wood, but topsail and lower yards would be built of tubular iron, like the masts; all three masts and spars to be of equal dimensions. The advantages claimed for the tripod over the ordinary system of masting are—1, Having no lower stays, they present no obstacle to the fire of the guns in the cylindrical shield or turret, in whatever direction they may be trained. 2, The yards can be braced up nearly fore and aft, or in a line with the keel, enabling the ship, when under steam, to set sail and steer her course when with the present rig she would be obliged to furl her sails. This last position was forcibly illustrated in the escape of the English steamer "Thistle" from the United States' corvette "Tuscarora," off Madeira, on the 29th of November. 3, In action, the wooden topgallantmasts being sent down, the ship is in her fighting trim. Her topsail halliards and sheets leading down between decks through her tubular masts, sail is set and taken in as required by the crew without exposing a man on deck. If all or any portion of the masts and yards are shot away, being of iron, and having no rigging attached to them, they would sink immediately on falling overboard, without a possibility of fouling the screw. 4, On the mast platforms, which are laid on the braces connecting the legs of the tripod, they furnish a set of fortresses for riflemen to repel boarders, &c. 5, From their great strength they are well adapted for withstanding the shock of a collision when using the ship at full speed as a ram. 6, They will enable a ship to carry a greater spread of canvass, with less weight aloft, than can be done with ordinary masts and rigging. They afford great means of ventilation, are durable as the hull of the ship itself, would not be subject to the effect of climate, and the enormous wear and tear of ordinary masts and rigging would be thus avoided. 7, The masts and yards being all equal in size, and fixed at equal distances, the yards cannot lock when braced sharp up, and, the centre of effort of the sails being thrown well forward of the line of resistance of the hull, the ship will wear easily and rapidly, a quality in which our iron ships afloat, and more especially the "Warrior" and the "Black Prince," are said to be very deficient. The adoption of the tubular tripod masts would also, without doubt, save the enormous annual expense which is now incurred in the deterioration of the rigging of our ships of war kept ready for service in the first-class steam reserves.

The following are the general dimensions of the shield-ship proposed by Captain Coles as a sea-going vessel, compared with the "Defence":—

	Shield Ship,		"Defence."
Length	285 feet	...	280 feet.
Beam	50 ,,	...	54 ,,
Tonnage	3,700	...	3,720
Draught of water	23 feet	...	26 feet.
Nominal horse-power	800	...	500
Height of guns out of water	13 feet	...	9 feet 6 in.

As regards the spread of sail and weight aloft, the following comparisons are drawn:—

	Area of canvass in square feet.	Weight in tons.
Ship with tripod masts	32,456	190
Defence	22,529	162
A first-rate, or 120-gun ship	29,705	226

This gives the tripod-masted ship a spread of 9,927 square feet more canvass than the "Defence," at an increase of 28 tons more weight. In comparison with the first-rate, by which the "Warrior" and "Black Prince" may be judged, the tripod ship spreads 2,751 square feet more canvass, with a less weight of 36 tons, and as the tripod shield ship would draw less water, and have less beam, it is claimed that she would be much the faster ship under sail.

The word "turret," made use of in referring to Captain Coles's ships, has been used advisedly, the sloping shields which were to crown the towers having been abandoned by the Admiralty, together with breech-loading ordnance for their armament. The "Royal Sovereign," at Portsmouth, and the "Prince Albert," building by Messrs. Samuda, will, therefore, now be fitted with turrets of a similar fashion to the "Monitor," and will carry as heavy muzzle-loading ordnance as can be made for them. The "Royal Sovereign" is not to be fitted with masts, and consequently can only be looked upon as forming a part of our home defences.—*Times.*

Grandeau has discovered rubidium in the ashes of the beet, in tobacco, coffee, tea, and raw tartar. The author believes that this metal is one of the more widely distributed elements, and that its presence is not necessarily associated with that of lithium, as might be supposed from the analyses of minerals and mineral waters.

THE SCOTCH IRON TRADE.

WE extract the following from the annual report of Mr. Thomas Thorburn, of Glasgow:—

"Scotland shows a marvellous progress in the development of the iron trade. The steam-engine, the hot-blast, and the railway system, have doubtless contributed to this prominent feature of our national prosperity. And it is to be recorded for the information of the world that, in less than half a century, the production of pig-iron has increased more than one hundred-fold. Seven years ago, the stock of pig-iron in Scotland did not exceed 100,000 tons. Now our wealth in this the most useful of metals has accumulated to at least 720,000 tons, which, calculated at the average price for the year, in sterling money, is £1,900,000, thus approximating to the amount of gold bullion held by the Scotch banks. And it may reasonably be expected that the combined, steady, and well-directed efforts of producers and capitalists will, in the course of two years, achieve the grand result of a stock of one million of tons. The quantity of pig-iron produced in the year just closing is computed at 1,080,000 tons, which, valued at the year's average price, represents £2,850,000 sterling. The exports, foreign and coastwise, combined with the local consumption, amounted to 970,000 tons. The stocks, therefore, show an increase of 110,000 tons when compared with the same period of last year. It may arrest attention that, whilst the stocks have been steadily increasing, the price has risen from 49s. to 57s. 6d. per ton. This has, no doubt, been owing to speculative operations in the article, based upon a sanguine belief in an early settlement of the American war; but the advance arising from this expectation has been very shortly maintained. The lowest price was 48s. in January, and the average for the year is 52s. 10d. per ton. The malleable iron-works, the foundries, and the ship-building yards on the Clyde, are generally well employed; and should the belief in the superior advantages and impregnable character of the iron-clad ship gain ground, it may reasonably be hoped that those great branches of national industry will continue to flourish. Since the Irish famine, which the great wealth and greater charity of this country encountered and overcame, there has been nothing approaching the enormous suffering and destitution arising from the cotton famine in Lancashire. But it is a matter of unspeakable satisfaction that the resources of this great country, including very particularly those derived from the successful development of the iron manufacture, are adequately alleviating this unprecedented distress. The hope may therefore be confidently entertained that the iron trade, as hitherto, will continue to increase; and that, whilst adding to the wealth of Scotland, it will contribute to the civilization and prosperity of the world."

HORNSBY AND SONS'S ROOT PULPERS.

PROVISIONALLY PROTECTED, Dec. 4, 1862.

IN our late account of the Smithfield Club Show, we promised our readers a description of Messrs. Hornsby and Sons's patent root pulpers and turnip cutters. These implements were among the novelties of the show. The accompanying engravings show the root pulper; the turnip cutter we intend to give next week.

These pulpers are fitted with single diamond-pointed knives of steel, each one fixed in separately with a wood wedge, so that they can be easily adjusted or replaced by any farm-labourer.

At the base of each knife there is a clearance hole through which the pulped roots pass. This reduces the power necessary to work the machine.

The cutters or knives are so arranged that "no two of them pass over the same track;" consequently the roots are equally cut over the whole surface, causing the cutting action to progress regularly.

To prevent the escape of the last piece, and to clear the cutters, the machines are fitted with a patent oscillating bar, having teeth through which the cutters pass, and which receives motion from an eccentric on the spindle. This simple arrangement does away with gearing or worms, and also prevents the material being squeezed, whereby the nutriment is lost.

MANCHESTER ASSOCIATION FOR THE PREVENTION OF STEAM BOILER EXPLOSIONS.

CHIEF ENGINEER'S MONTHLY REPORT.

AT the last ordinary monthly meeting of the Executive Committee of this Association, held at the offices, 41, Corporation-street, Manchester, on Tuesday, January 6th, 1863. (William Fairbairn, Esq., C.E., F.R.S., in the chair), Mr. L. E. Fletcher. chief engineer, presented his monthly report, of which the following is an abstract:—

"During the past month, ending December 31st, 1862, there have been examined 430 engines—3 specially; 621 boilers—12 specially, 9 internally, 54 thoroughly, and 556 externally, in which the following defects have been found:—Fracture, 4; corrosion, 33 (1 dangerous); safety valves out of order, 13 (2 dangerous); water gauges, ditto, 24; pressure gauges, ditto, 9; feed apparatus, ditto, 1; blow-off cocks, ditto, 32 (1 dangerous); furnaces out of shape, 7 (2 dangerous); blistered plates, 1. Total, 124 (6 dangerous). Boilers without glass water gauges, 6; without pressure gauges, 16; without blow-off cocks, 27; without back pressure valves, 44.

EXPLOSIONS.

"While I am happy to be able to report that no explosion has happened during the past month to any of the boilers under the inspection of this association, the occurrence of five explosions in other quarters during that period has come to my knowledge. Each of these has been attended with fatal consequences, 26 persons in all having been killed, and upwards of 32 injured. Two of the exploded boilers were personally examined.

"The first of these explosions, and from which 10 persons were killed and 26 injured, occurred at an iron works. The boiler was a horizontal one, of plain Cornish type, with a single internal flue, and a longitudinal steam chamber fixed above the shell. It was heated, as his common in such works, by the flames passing off from the iron furnaces; the flames of one of these passed through the internal flue in one direction, and those from two others passed outside the shell in the other direction. The furnaces were placed immediately at the ends of the boiler, one at one end and two at the other.

"The dimensions of the boiler were as follow:—Length, 25 ft.; diameter of the shell, 5 ft. 3 in.; of the internal flue tube, 2 ft. 3 in.; thickness of the plates, three-eighths throughout, with the exception of the flat ends, which were half inch, and strengthened with gussets in the ordinary way.

"The wreck was so complete that scarcely a trace of the fittings remained; but they are reported to have consisted of two safety valves 2¼ in. in diameter, a float, and glass water-gauge; which latter, however, had been broken a short time previous to the explosion; while there remained on the ground the feed back pressure valve and the feed stop tap.

"The load on the safety valve was stated to have been 70 lb. on the square inch; but the boiler had not been fitted either with a steam pressure gauge or with a tap for applying the indicator, so that no means had existed of checking the actual pressure when the steam was up.

"The rents in the boiler, as well as the flight of the parts consequent on explosion, were extremely complicated, and are difficult clearly to describe. Generally, it may be stated that the shell and internal flue tube had been completely torn asunder one from the other, and that each of the end plants, gusset stays and all, had been wrenched from both shell and tube. To go more into detail. The shell had been rent transversely into two parts, and the longitudinal steam chamber dismantled. The internal flue tube had collapsed and separated into four lengths, fracturing at the ring seams of rivets. The longtitudinal seams which were at the sides of the tube ran in line from one end of it to the other, and the collapse, which is usually vertical, was in this case lateral, and had brought these longitudinal seams from each side of the tube close together. This was the case in each segment of this disjointed tube. The end plates, which had been built in pieces, were separated at each of the seams, and disengaged from the shell and flue tube by shearing both rings of angle iron. One gusset adhered to the end plate, but in the main they were torn away from both end and shell. There were many minor fragments, which were completely curled or crumpled up.

"With regard to the flight of the parts generally, the shell had flown in one direction and the internal flue tube in the other; although this admits of some exception, one portion of the tube being found alongside the shell in a contrary direction to the others. The end plates had also flown in directions opposite one to the other, the fragments of each being scattered a considerable distance apart, and some of them flying to a greater distance than either the flue tube in one direction or the shell in the other.

"The devastation to the surrounding property from the explosion was very considerable, arising greatly from the fact that the heavy portions of the boiler had taken a horizontal raking course, the shell flying into the heart of the works, where it swept the columns, and thus brought down a considerable portion of the roof, and also struck and broke in pieces a heavy rolling mill fly-wheel then in motion. Boilers flying vertically are seldom productive of an equal loss either of life or property. The damage, however, was not confined to that done by the flight of the parts. The percussive action of the steam had shot in every direction the bricks, many of them red hot, from the furnaces previously referred to as built at each end of the boiler. The chimney, about 130 ft. high, was scarred to the top, showing the height to which the parts had been thrown.

"The cause of the explosion was attributed at the inquest to shortness of water, which leading to overheating of the plates had, it was supposed, on the re-introduction of the feed, resulted in a sudden and excessive pressure of steam. This was imputed to the carelessness of the engine tenter, and the jury found him guilty of manslaughter, in consequence of which he was committed to the next assizes for trial.

"There is good reason to question the correctness of the above conclusions, and to attribute the explosion to other causes than shortness of water and the negligence of the engine tenter.

"The pressure of 70 lb. to the inch, at which the safety valves were stated by the manager of the works to have been loaded, was excessive for a boiler of such construction; not so much so for the shell as for the internal flue tube, the latter not being half the strength of the former. This must have been the case even when the boiler was new, and if the tube was perfectly circular; but since then the tube had been repaired, in consequence of overheating, and very frequently a good deal of straining occurs in replacing old plates; also, many tubes are found on actual measurement not to be truly circular, although nominally so; and had this been the case in this instance, its strength would have been considerably less than half that of the shell. In attempting to unravel the complicated rents produced in boilers on explosion, it is important to bear in mind that girder strains and leverages, the amount of which it is difficult to calculate, are induced in the plates as soon as the statical equilibrium is disturbed by the occurrence of a rent. Collapse of flue tubes has been found in other cases to break them up into short lengths at the ring seams, and to sheer the end angle irons through at the roots, as was the case in this instance.

"Upon careful consideration of all the circumstances, to enumerate the whole of which would be tedious, there appears every reason to believe that the explosion resulted from the collapse of the flue tube consequent upon its inherent weakness, and not from shortness of water; while that collapse might have been prevented, either by the introduction at the time of the construction of the boiler, of flanged seams, or hoops of T iron, angle iron, or other approved form, or else by the addition to the flue, since it was made, of angle iron hoops.

"The second explosion, which resulted in the loss of three lives, was of a much simpler character than the one just referred to, and occasioned scarcely any damage to property.

"The boiler was of plain double-flued internally-fired construction, such as is in general use at cotton mills in Lancashire. Its length was 25 ft. 6 in.; the diameter of its shell, 7 ft. 6 in.; and of its internal furnace tubes, 2 ft. 10 in.; the thickness of the plates in both being from three-eighths to seven-sixteenths. The fittings were complete as to number, as well as satisfactory as to condition, and all that was necessary with due care for safe working. The working pressure was stated not to have exceeded thirty-five pounds, and there was no reason to doubt the correctness of this, while the boiler was perfectly capable of working safely at a much higher pressure, as long as it was in good condition.

"On examining the boiler, it was at once apparent that it had not exploded either from excessive pressure or shortness of water, but from thinning of the plates through external corrosion, from which a rent was found to have occurred in the last ring of plates of the shell in the left-hand flue immediately above the brickwork on which the boiler rested, it being set on what are termed side walls. This rent extended longitudinally through the solid of the plate, throughout its whole width, from one ring seam of rivets to the other, but opened only a few inches transversely forming a slot, the edges of which were blown outwards into the form of lips. The plate at this part was reduced by corrosion to the thickness of a sheet of brown paper, and some pieces were broken off with the fingers by one of the jury as specimens. It may be added, that daylight could be distinctly seen through the adjoining plate, which had not been disturbed from its original position by the explosion, but was completely eaten through by corrosion in the form of veins, so that either leakage must have been going on at this part for some time, which, however, it can scarcely be imagined could have escaped detection, or else the plate must have depended on a coating of scale, such as was to be found in other parts of the boiler, for keeping it tight.

"It is unusual for a longitudinal rent in a cylindrical shell to confine itself to such narrow limits as this had done, and the fact is to be attributed to the proximity of the end plate and the lowness of the working pressure.

"The rush of steam and water had blown up the upper part of the brickwork flue, but the boiler was not moved from its place, and no further damage to property appeared to have been done. The loss of life occasioned by the explosion resulted from scalding, the persons killed being in the boiler-room at the time.

"The corrosion which, as previously stated, was external, was caused by damp in the flue, the plates being most seriously affected for a considerable distance along the seating, in addition to the part actually rent. This was at once apparent upon entering the flues, where large cakes of oxide were readily collected. Competent inspection could not have failed to have detected the corrosion and prevented the explosion. The flues were stated to have been swept out about once a year, only, whereas this should be done at least every three months, not only to prevent the loss of fuel that must result from an accumulation of soot, but also in order to afford an opportunity of examining the condition of the plates.

"The present may be a fitting occasion for again urging upon the members of the association the importance of affording the opportunity of making 'internal and thorough' examinations of their boilers. The facts of the second explosion speak for themselves; while in connection with the first, with reference to the collapse of the flues, it may be stated that when these 'thorough' examinations are made, the flues are then gauged in order to check their circular shape; this is too frequently found to vary as much as one or two inches from the truth, which has a considerable influence upon their safety, and may render strengthening hoops necessary where otherwise unsuspected."

PROGRESS DURING THE YEAR 1862.

"The following points have been accomplished during the past year:—

"It is gratifying to find that the members now appreciate more fully than heretofore the importance of annual 'thorough' examinations, and that the number has consequently increased from 434 in the year 1861, to 820 in the year 1862; thus, as it will be seen, having almost doubled this last year as compared with the previous one.

"Still, the privilege afforded by the association is an 'internal and thorough' examination of every boiler once a year, so that the full number has not even yet been attained, and members will not drive that safety from the serivce of the association which they might, until every boiler, without exception, is examined by its inspectors, both 'internally and externally' every year.

"The introduction of 'surface blowing-out' for the removal of incrustation—a difficulty most severely felt in this district, both by inspectors and steam users—has, during the last year, made considerable progress. There are three different kinds of scum-pipes now in use. One entirely free from patent right, and which may be made and applied by any one, and was described in the printed abstract of the monthly report for October last, and two others, both of which are patented, one being termed the 'Needham' and the other the the 'Shepherd' scum-pipe.

"A surface-condenser is being applied to a pair of cotton-mill engines, by which means a constant supply of distilled water for the boilers will be secured. This, in many situations, will prove most valuable, since water, otherwise quite unfit for use, will thus be rendered serviceable.

"Steam-jackets, so long discarded in this district, have been revived and fitted to the cylinders of some new engines lately laid down, while others are being added to a pair of beam engines already in work.

"A superheating apparatus has in two or three cases been applied, for raising the temperature of the steam in its passage between the boiler and the engine.

"Each of these movements has an important bearing upon the economic use of steam in this district, and it is thought that information with regard to them will be highly valuable to the members of the association, and, therefore, the results of the working of the whole will be fully investigated and reported to them. The delay in completing the engines fitted with steam-jackets, consequent upon the depressed state of trade, has prevented their economy being tested during the past year, and with regard to the superheating apparatus, had been in full work for a long period; but the economic result both of the use of the steam-jacket, and of superheating steam, will now be taken into consideration early this year.

"It may be added, that there lies at the office, for the inspection of the members, a drawing of the scum-pipe referred to, as well as the arrangement of feed-apparatus found to be most convenient. Also a drawing of the method of adding strengthening hoops to flues of boilers when in position; from which, through the neglect of suitable precaution, many flues have been injured, and considerable expense incurred by our members. Also there is a drawing of the method of setting boilers found to be most approved with the best proportions of flues. The plans upon which many under inspection are set are most capricious, and defy all attempts to examine the plates.

"A considerable number of 'dimension-sheets' of boilers under inspection have been added during the past year to the previously very numerous stock in the archive of the association. These show the peculiar construction of each boiler taken; and since, in addition, records are kept of their working, and the repairs they are found to require, these records form a valuable reference for members who are intending either to repair old boilers or lay down new ones. A consultation of these at such times would enable one member to profit by the experience of another, indeed by that of the whole number. Thus any repetition of failures would be prevented, while the success of one would prove of advantage to all. It is thought that this branch of the service afforded by the association is of itself of considerable commercial value to steam users, that it must tend, step by step, to the improvement of steam-boilers, and to the completeness of all their arrangements; while such a service could only be rendered by some such system of organization as is to be found in this association.

"L. E. Fletcher, *Chief Engineer.*"
Offices—41, Corporation-street,
Manchester.

HUDSON'S ARMOUR PLATED SHIPS, &c.

The accompanying engravings represent a curious idea for an improved defensive armour for ships, &c., recently patented by Mr. C. Hudson, of Roxbury, U.S.

The object of the invention consists chiefly in the use of certain means, appliances, and arrangements, for the purpose of lessening the percussion of projectiles upon the backing or supports of metallic armour, by the introduction of water between the supports and the protecting armour, and also around its fastenings. This is effected by covering the surfaces exposed to the action of projectiles with a metallic structure, of a cellular form, presenting a strong surface to the action of the projectile, and, from its construction, capable of holding and retaining water within its cells, or between its inner surface and that of the supports or backing. This arrangement, or system of defensive armour, is applicable to all kinds of objects, whether moveable or fixed, on land or water, although chiefly applicable to ships.

The beneficial results to be obtianed from the introduction of water between the armour plates and their supports are based upon two well-known properties of water, its almost total incompressibility, and its power of transmitting force equally and in every direction. The patentee prefers that the water should be distributed, whether within or behind the structure of the armour, in divisions or compartments, so that the destruction of any one division would not materially affect the perfect action of the others.

The arrangement shown at Fig. 1 is formed of hollow blocks, having ribs and flanges for bolting them to the skin of the structure.

Fig. 2 shows an arrangement of tubes: two rows are shown in the engraving, but any number of rows may be used. Fig. 3 illustrates a series of troughs placed between the outer plating and skin. These troughs are intended to strengthen, at the weakest point, the resistance of the plates, and also the frame of the ship, but they also serve to separate the compartments for the water, which may be introduced whenever requisite.

HUDSON'S ARMOUR PLATED SHIPS, &c.

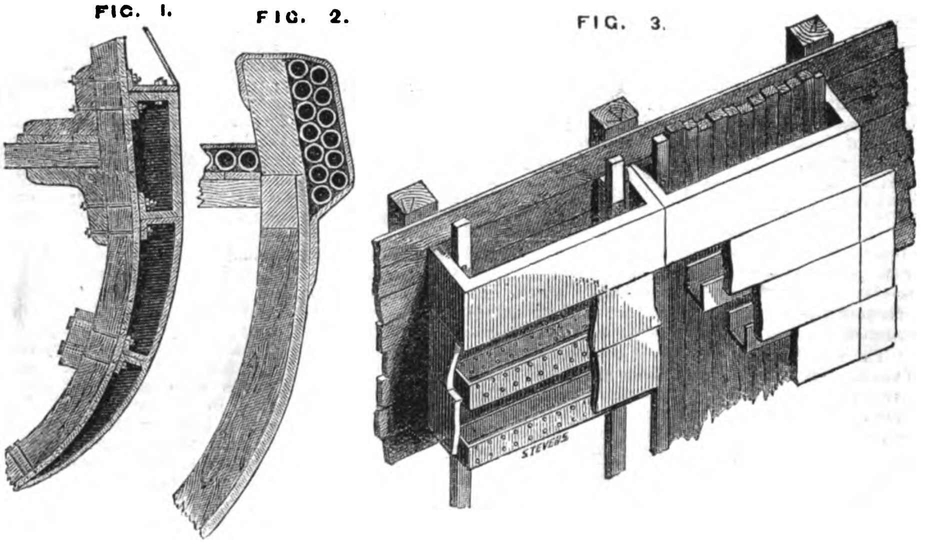

FIG. 1. FIG. 2. FIG. 3.

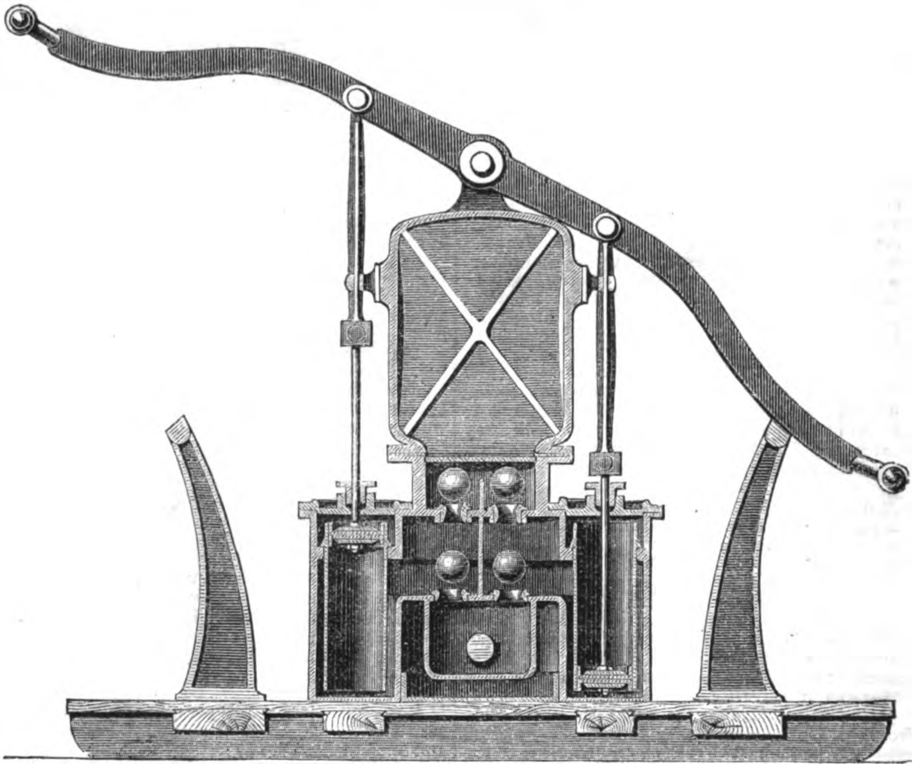
DELPECH'S PATENT PUMP.

The following is an account of a series of experiments with a new pump, the invention of M. Delpech, of Castres, France. The experiments took place at Nine Elms, in the presence of several scientific and other gentlemen interested. The accompanying engravings represent the arrangement of the various parts.

In appearance, the Delpech pump is not unlike that of a stove, and is susceptible of a horizontal or vertical arrangement. The apparatus consists of a metallic casing divided into two compartments — a cylinder chamber containing the cylinder in which the piston works, and a ball chamber which contains four elastic acting balls as valves or clacks. Both those compartments are again divided into two parts, each portion of the ball chamber, however, communicating with one of the divisions of the cylinder chamber by a free opening. The ball chamber is always in a vertical position. The two balls in the lower compartments are intended for suction, the other two directly over them, in the upper compartments, are intended for forcing the water. These balls rest on bronze seats, and are free in their action, alternately rising and falling with the action of the piston, and therefore alternately opening or closing the orifices which they occupy. The piston is composed of lipped discs of a flexible substance, each having inside a ribbed metal washer. The discs are set back to back in opposite directions and the piston rod passes through them. By this arrangement, again, loss from friction is avoided in the working of the piston. The pump may be used in a horizontal or vertical position, according to the nature of the work to be required from it. The horizontal pump may be fixed on a portable steam or traction engine, and the piston connected with and worked direct from the shaft, thus forming but one machine for draining, irrigation, and especially for extinguishing great fires in towns, docks, arsenals, warehouses, railway stations, and wherever sufficient water can be found to feed it. As a portable pump it may be conveyed on any convenient vehicle, and worked by any convenient motor directly, or by gearing, and when used for draining or irrigation it is inexpensive. It offers facilities as a stationary pump for draining mines and quarries; and on board vessels, especially steamers, it can be placed in the hold, and worked direct from the shaft, being thus protected from shot during action. It may, moreover, be used as a formidable engine of defence on board ship, as boiling water may be projected on a boarding party from a great distance and with destructive effect. M. Delpech claims for his pump an effective power of 70 per

DELPECH'S PATENT PUMP.



cent. of the force exerted; whereas the average power of the ordinary pumps, as proved by dynamometric tests, is below 35 per cent. For example, the vacuum of a Delpech pump, having a cylinder of 9.84 inches diameter, with a stroke of 9.84 inches, attached to a portable steam-engine, would equal 2,696 gallons, and the piston being double acting, there would be a net product of 5,062 gallons for each double stroke of the piston, consequently 50 revolutions would amount to 253 gallons per minute, or 15,180 gallons per hour; and supposing the pump to be supplied at 19,685 ft. below where it is placed, it then would have to raise 4.216 gallons of water per second, representing a power equal to 829.9 lbs. The effective power being 70 per cent. of the power exerted, and one horse-power being equivalent to 550 lbs. of the liquid, raised one foot high per second, it would follow that the pump would require but little more than two horse-power of the portable steam-engine to work it. The air chamber of the pump is arranged to receive two hose and two branch pipes for the same, the hose having .669 of an inch opening; each branch throws out from 120 to 130 gallons of water per minute; so that a fire can be played upon at two places at once by one engine, But, if a single delivery hose only be employed with an .866 of an inch opening, 240 to 260 gallons of water are thrown per minute 160 ft. in height.

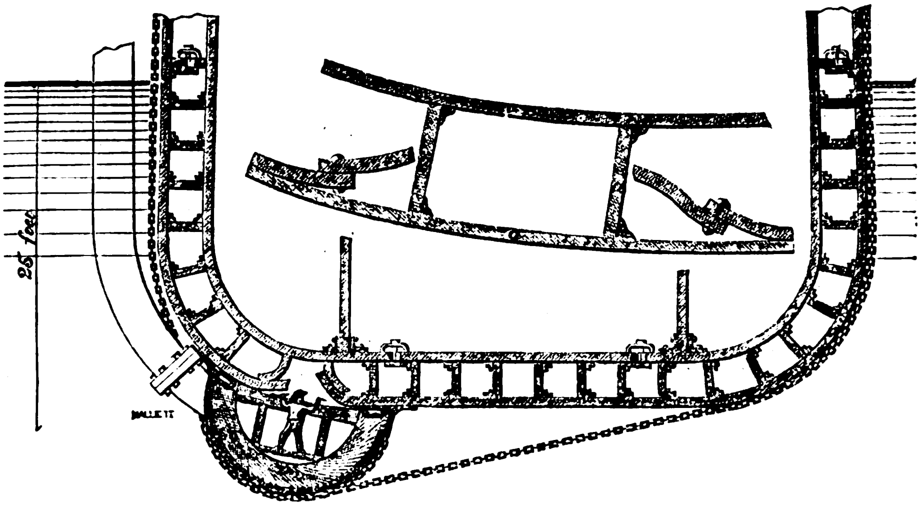
The experiments, though not tried under the most favourable circumstances, were entirely satisfactory. All foreign bodies, not exceeding half the diameter of the suction pipe, will pass through, and if an obstruction does take place from the presence of too large a foreign body, the machinery affords a simple means of removing it with the least possible loss of time. This was proved in the experiment. The distinctive merits, then, claimed for the locomobile pump are that the liquid raised follows a direct course free from all impediment—that it undergoes no interruption of motion from the dead point, which is inevitable in the common system of pumps in use, and avoided in this system by the arrangement of the apparatus, since the instant one ball drops to close its orifice, the other rises to open its orifice—its effective force, in comparison with the power used, as it yields nearly 70 per cent.—the ease with which the pump raises and ejects all kinds of foreign matter mixed with the liquid, without causing any obstruction to its parts, or lessening in the least its delivery, such as ores, cinders, coals, rags, grit, pieces of rope, oakum—in short, all matter whose size does not exceed one-half of the diameter of the suction-pipe.

It is employed in the mercantile marine of France, and has been adopted in the French navy, after a strict competitive examination, conducted by the naval authorities of France. It has also been tried at Woolwich, and a favourable report made of it by the authorities at that establishment.

REPAIRING THE "GREAT EASTERN."

THROUGH the courtesy of Messrs. Howland and Aspinwall, and the personal attention of Capt. Walter Paton, of the "Great Eastern," we are enabled to lay before our readers a full and succinct account of the disaster which befell this celebrated ship, and also details of the plans which were employed to repair her, together with the trials and delays which took place during the progress of this extraordinary feat of hydraulic and mechanical engineering. After the occurrence of the accident (with the history of which our readers are already familiar, from a recent article in the *Scientific American*), a preliminary survey was held, in order to estimate the precise locality and extent of the breakage. This was accomplished by divers, who went under the bottom of the "Great Eastern," and, on returning, reported their observations. They announced that the plates upon the port side were badly damaged, and that the fracture extended a distance of some 12 or 15 feet. Subsequent investigation disclosed the fact, that these figures fell short of the actual injury by some feet.

REPAIRING THE "GREAT EASTERN."



The primary object of the survey being accomplished in ascertaining the nature of the injury, it only remained to invent some method by which it could be remedied. This was not imperatively necessary by any means, as, from the peculiar construction of the ship, eminent engineers declared that, even with this enormous hole in her bottom, she might ride the sea with perfect safety. The anxiety and care of the officers, however, as well as the increased labour to the crew, attendant upon this huge tear in the ship's plating, decided the question; and the work was immediately prosecuted with vigour.

Owing to the huge dimensions of the "Great Eastern,'" and the fact that there is not a dry dock in the world which will admit her, or sustain her immense weight, it will be seen that to repair a damage of this nature, some 25 ft. below the water-line, was an undertaking of no small magnitude. By referring to the section of the vessel, drawn for us by Capt. Paton, which we have had engraved (not however to scale), the precise locality of the fracture can be seen, as well also as the construction of the vessel itself. The character of the damage, and the bearing it has upon the seaworthiness of the "Great Eastern," will be understood by referring to our engraving. The hull is formed of two distinct vessels, as it were, one inside of the other. These skins are stayed to each other by a number of webs or partitions, that divide the vessel transversely into thirty-four spaces; they run the whole length from stem to stern. The webs are further crossed at right angles by thirteen separations, which constitute a system of water-tight cells, each of which is entirely independent of the other, access being had to each cell by man-holes, provided with plates that open into them. It must be borne in mind, also, that there are, inside of the ship proper, two upright iron bulkheads that divide the hull into three long rooms. Now the man-hole plates previously mentioned communicate with each other from the upper series of cells in the ship's broadside down to the foot of the bulkhead before mentioned. There they stop. The arrangement on the other side is, of course, similar. The inner room has two man-hole plates on the inner skin, which allow access to the cellular divisions situated beneath it. These are connected through one another by the same plan as the others. In brief, the "Great Eastern" is a ship built up of a series of rectangular pipes, independent of each other, yet capable of being connected together.

Let us now return to the subject of the disaster. The fracture was entirely through the outer plating of the ship, extending over three of the longitudinal cells, and running fore and aft for a distance of 86 ft. To close up the sides by any other means than with new plates was simply impossible, and these had to be put on while the vessel was in the water at her anchorage. The stubborn broken plates, with their ragged edges, afforded not the slightest hint that could be seized upon to accomplish the work short of much time and labour. Preliminary consultations resulted in deciding the authorities to adopt the expedient of a dam, which should inclose the point of rupture on all sides, and which, by means of pumps, could be freed from water and rendered habitable while the operations were in progress.

It may be inserted here, not inaptly, that the idea of employing such a dam was suggested to Capt. Paton, some time since, by an accident which previously occurred to the "Great Eastern," when going on to the "gridiron" at Milford Haven, England. The accident referred to was the springing-in of one of the plates of the ship's bottom, caused by coming in contact with a log upon which the vessel's weight came when taking her position. Capt. Paton mentioned his plan to the Messrs. Renwick Brothers, the well-known engineers of this city; it was approved of as practical by them, and they then devised the crib herewith described.

The coffer-dam was built of heavy oak timber, semi-circular in form, and planked outside 4 in. thick. It was ascertained that 32 tons of iron would be required to sink the scow, and it was forthwith partially submerged, while two chutes, hereafter mentioned, were affixed. Previously, however, two heavy chains had been attached to each side of it, in such a manner that the cable, fastened on to the larboard side of the dam, was carried under its bottom and rendered up on to the starboard side of the main deck, and *vice versa* in respect to the other cable. From the ends representing the bow and stern of the dam, there also ran large hawsers, which kept it from going adrift in either of those directions. Power was then applied, and the wooden crib hove up against the ship's bottom. Around the parasitic structure were then carried other hawsers and cables, until it was firmly secured in place. Thus far, matters progressed favourably—the dam was in its place, but it was full of water. Two huge chutes, or funnels, which pierced the sub-aqueous box on one side, 10 ft. from the ends, ran up a short distance above the water-line, and furnished the means of reaching the fracture. The edges or gunwale of the dam, must, as will be apparent, be made water-tight, else the pumping might be continued indefinitely, without any result. This it was proposed to accomplish by means of some elastic material; hence, india-rubber, flock mattrass, or substances of a like nature, were suggested for the purpose, but not being available, a plan of the Messrs. Renwick Brothers was put in force.

It occurred to the Brothers Renwick that a water-hose would be just the thing. After the details of its construction, for which we have no room, had been worked up, it was soon applied, and filled all the expectations formed of it. No sooner was the means discovered for obviating one trouble, however, than another appeared. This latter vexation was caused by the difficulty of overcoming the tendency which the hose had to draw in under the compartment. In order to secure it, strips of canvass were attached to one of two battens which armed the gunwale dam; these were carried under and over the hose at intervals, in such a manner that the latter lay in the bight of the former; the flying end was then fixed to the batten again. Upon the outside of the case, or dam, a lappet of Brussels carpet was secured, which the water kept up against the "Great Eastern's" bottom, aiding materially in keeping the sea out; weeds were also thrown into whatever crevices might remain, and the projectors of this ingenious method were rewarded for all their time and trouble by its complete success. To all the unequal surfaces the water-hose opposed its soft and elastic surface, filling up cavities which could not be effectually closed by any other means. The pumps were again tried, and the crib was pumped dry. No sooner was this consummation attained than Capt. Paton descended the chute to the scene of the fracture. Here an extraordinary sight was presented. The vessel was covered with long weeds, and from the cavity in the plates there rushed a waterfall on a small scale; this was perplexing, and was supposed to arise from the fact of some of the valves which communicated with the ship's bottom being open. It was found to proceed from other causes, which were soon remedied. Some water yet remained at the bottom of the box, through which Captain Paton, followed by Peter Falcon, an experienced diver, forced his way, finally emerging at daylight through the other chute. His arrival afforded the best possible assurance of safety to the mechanics who, not unreasonably, hesitated to venture into such an "uncanny" affair. The moral support given to the cause by Capt. Paton's conduct re-assured the doubters, and they prepared to fall in with vigour. It might be expected that here the Fates adverse to this scheme would have been appeased with their former interference; but such is not the case. During the last month, on the occurrence of the violent snow-storm, the great ship dragged her anchors, and parted one of the cables which kept the dam in place. This line immediately, as a matter of course, got about the pump-shaft, which was at that time operated in the sea, and tore it away from its connection, filling the whole dam full again. The pump was then rigged so as to prevent the occurence of a like disaster.

Supposing free access to be had to the fissure, let us examine the nature and character of it. It extended for a distance of 86 ft. in length, by 9 ft. 6 in. at the widest part, narrowing to a point at either end, and was a ghastly wound in the ferruginous cuticle of the monstrous vessel, which, while it did not impair the sea-worthiness of the ship, was of sufficient importance to warrant attention. Three of the cells were broken into, and two of the longitudinal webs upset and sprung out of place for a distance of 10 ft. As it was impossible to add anything to these last-named parts, a plan was put in force whereby the wounded and disunited plates were made one and indivisible again. The diagram will convey an accurate idea of this method. The new plates, *a*, are laid athwart-ship over the fissure, and fastened with hot rivets to the old ones; braces are also annexed, which represent the vertical divisions of the cells. The plates in the vessel's bottom are seven-eighths of an inch thick, but the patch is only five-eighths; it is, however, of the best charcoal boiler iron, and is deemed equivalent in strength to the original structure. Great delay has occurred in getting the new plates in place, for the reason that they could not be supplied by the manufacturers as fast as they were wanted. This trouble has been remedied, like all the others; and we have the satisfaction of announcing, from a personal inspection of the job, that it is completed in a substantial and workmanlike manner. The inside of the dam is very comfortable indeed, and the workmen, we are assured, made no complaints in this respect. They were at work continually, and inasmuch as their labours would have been materially retarded by visitors, no one beside the workmen, not even the ship's officers, were allowed to descend the chute.

The ingenuity and perseverance evinced in adopting this novel apparatus, and making it work practically, is something remarkable; and its projectors, Capt. Paton and the Renwick Brothers, have reason to feel satisfied with it.

Since the above article was written, we have visited the "Great Eastern," and descended into the scow just described. We went through the whole affair without any protection to our garments, and came out unharmed by wet or grease. We must, however—compelled by the inexorable laws of column-rules—omit further details. On this occasion, which was one devised to give the press and the reporting engineers an opportunity of satisfying themselves by occular evidence that the ship was all sound again, Capt. Paton entertained his guests in a hearty and hospitable manner, placing before them on his board the finest viands and wines. At the conclusion of the festivities, a gentleman having proposed the health of Queen Victoria, Capt. Paton responded modestly, and returned, "The President." Various other toasts were given, and the guests dispersed, highly pleased with their cordial, truly British reception. As the steamer which had conveyed the visitors to the vessel steamed away upon her return trip to the city, the band of the ship, stationed on the wheel-house, delicately complimented the disappearing boat with national airs, to which, also, the crew added force, by giving lusty cheers for the Union. Long after the responses which followed these demonstrations had died away in echoes, "the martial strains of the inspiring brass" sent forth "Hail Columbia" and "Yankee Doodle," with a vigour that excited the most lively enthusiasm for, not only the compliment which was conveyed, but also the hospitable entertainer, Capt. Paton.

A series of resolutions highly complimentary to Capt. Paton and the Messrs. Renwick Brothers, were passed by the guests on their return to the city, which we are compelled to omit.—*Scientific American.*

Meetings for the Week.

MON.—*Royal Inst. British Architects*, at 8 p.m.
London Inst., "On Sculpture," by R. Westmacott, Esq., at 7 p.m.
Royal Geographical Soc., Sir R. Murchison in the chair. 1, "Ocean Currents on the N.E. Coast of South America," by J. A. Niann, Esq. 2, "Ocean Telegraphy," by Captain Powett. 3, "Survey of the Atlantic, with regard to Telegraphic Communication with Europe and America," by G. C. Wallich, Esq., M.D., at 7.30 p.m.
TUES.—*Inst. Civil Engineers*, "On Railway Telegraphs, and the Application of Electricity to the Signalling and Working of Trains," by W. H. Preece, Esq., at 8 p.m.
WED.—*Soc. of Arts*, "On Photography and the Magic Lantern, Educationally Considered," by S. Highley, Esq., at 8 p.m.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our Correspondents.*]

◆

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to M. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 6 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of his good faith.

TO CORRESPONDENTS.

RECEIVED.—Capt. C. C., W. A., G. C., N. C., J. M. D., C. B. (thanks).

FRED. (Lincoln).—Double shrinkage must be allowed for the original wooden pattern, in forming a pattern of cast iron.

S. M.—You would have to enter upon a recondite business at 26 years of age, in which most men have made a beginning at 16.

J. S.—You can get the railway report by ordering it through any bookseller.

M. P.—It will appear next week.

TENSILE STRENGTH OF IRON.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In support of Mr. Kirkaldy's conclusion, No. 18, and in answer to your correspondent "Ignoramus," allow me to refer the latter to an experiment cited in a short paper by myself, "On the Structural Changes in Iron from Vibration and Concussion," which appeared in your Magazine vol. 51, page 561.

The same experiment is also mentioned in one of your volumes for the year 1847, (vol. 47, page 626). I have repeated it many times since, and it proves conclusively to my mind that the appearance of the fracture of iron varies according to the method of breakage.

I am, &c.,
JAMES ROCK.

Hastings, January 4th, 1863.

Gossip.

A new permanent bridge, connecting the North and South Camps at Aldershott, has just been opened, replacing the pontoon bridge over the Basingstoke canal, which has been a source of many melancholy accidents. The bridge has been constructed by the 10th and 24th companies of the Royal Engineers, stationed in camp. It is situated parallel to E, F, G, and H Lines, North Camp, by which it is connected by a splendid road across the heath, the work of the convicts at the military prison. The bridge is constructed of iron girders, supporting a wooden framework, with a raised footway on each side, leaving a roadway of 18 ft. for carriages. By its means access to either camp will be more direct.

It is said that Messrs. Jones and Quiggin, of Liverpool, will shortly launch a steamer of 250 tons burthen, built of steel plates only 3-16ths of an in. in thickness. The Liverpool *Journal of Commerce* states that she is intended for a "peculiar trade." and that she will steam 20 knots an hour.

Mr James Bruce has succeeded in determining the influence of electricity in promoting the growth of seeds, roots, &c., which have been made to germinate in less than ten hours, by placing them in a zinc cup fitting into a tin-cup, and placed in a basin holding the acid bath.

At the last meeting of the Council of the British Horological Institute, Mr. Hislop exhibited some specimens of ten per cent. aluminium bronse, with the view of showing its qualities in relation to oxidation or tarnishing. It has been stated that it scarcely tarnishes at all in ordinary atmospheres, and if it does, it does so slowly. The specimens shown had been polished but a few hours, but they exhibited very decided marks of tarnishing, although only exposed to the ordinary atmosphere of a town. The actual amount of oxidation was considerably more than would have been shown by hard rolled or hammered brass in the same period of time. The use of this compound metal has been recommended for the fine work of watches and chronometers, as not requiring gilding, because it does not tarnish, but the facts do not appear to be exactly in accordance with what has been stated. Moreover, if the metal tarnishes so readily, what would be the probable effect of the oil applied for lubrication of the surfaces?

According to the *New York Tribune*, in the week before Christmas there were 520 presses, "in full blast," making postal currency.

The next general meeting of the members of the South Wales Institute of Engineers will be held at the Castle Assembly Room, Merthyr Tydvil, on Wednesday, Jan. 14. The chair will be taken at 12 o'clock noon. The following papers, read at former meetings, will be discussed:—Mr. Cox's, "On the Selection and Treatment of Coal for the Blast Furnace and Cupola;" Mr. Parry's, "On

Puddled Steel;" Mr. H. T. James's, "On Mining in the County of Leitrim;" Mr. Waring's, "On Coal-cutting Machinery." And the following papers will be read and discussed:—"On the Selection and Value of Coke," by Mr. Child; "On Long-work," by Mr. Hedley; "On Boiler Explosions," by Mr. M. Jones. The Council Meeting will be at 11 a.m.

Another important addition was made on Tuesday to the Royal Navy by the launch of her Majesty's iron screw steam vessel, "Tamar," of 2,811 tons, and 500-horse power, from the premises of the builders, Messrs. Samuda, Poplar. There was a large number of spectators. After launching the vessel was taken in tow, and hauled into the East India Docks, under the mast-house, where she will be fitted with her screw machinery and engines, manufactured by Messrs. Ravenhill, Salkeld, and Co. The "Tamar" was laid down in November, 1861, and is in every respect a fine vessel. The following are her principal dimensions:—Length, 300 ft.; breadth, 44 ft. 7 in.; depth in hold, 34 ft.; burden in tons, 2,811 82-94 old measurement. After receiving her machinery she will be removed to Woolwich Dockyard to be rigged and fitted with her armament, consisting of four rifled guns, and she is expected to be ready for service by April next. A large number of workmen are now employed at the premises of Messrs. Samuda upon the construction of her Majesty's armour-plated screw cupola ship "Prince Albert." She will be iron-cased throughout with 4½ in. plates, and fitted with four armour-cased shields or cupolas, of immense strength, upon Capt. Coles's plan, recently adopted by the Admiralty. She is the first cupola ship laid down for the Government, and is named the "Prince Albert" by express desire of her Majesty. The armament of this magnificent vessel will consist of eight monster rifled guns, two of which will be fitted in each cupola.

The Universal Private Telegraph Company have issued a new prospectus in consequence of the Board having been strengthened by some Manchester names. The company is already in operation, more than 2,000 of their 7,600 shares, of £25 each, having been originally subscribed. The remainder are now offered to the public.

It appears that the business recently carried on by Messrs. Mare and Co., of Millwall, is now under the superintendence of a limited liability company. We find from the *Army and Navy Gazette* that there is considerable activity on the premises. In the ship-yard there are building, the Government frigate "Northumberland," armour-plated, 50 guns, 1,350-horse power, 6,626 tons; P. and O. screw steam ship, 400-horse power, 2,300 tons; Italian cupola ship, armour-plated, 700-horse power, 2,300 tons; Spanish iron-cased frigate, armour-plated, 1,000-horse power, 4,800 tons; three iron sailing ships, 1,000 tons each, 3,000 tons; one iron paddle steamer for the opium trade, 230-horse power, 900 tons; and two paddle steamers, 800 tons and 1,000 tons, have just been contracted for, and are about to be laid down; total, 21,726 tons. In addition, in the rolling mill department, the massive iron work (wrought iron caisson) for the new Blackfriars Bridge is in a state of forwardness, and so are a considerable number of bridges for the Metropolitan and Kent Coast Railway. The plates for the cupolas of the "Royal Sovereign," and the plates for a target ordered by the Government on Mr. George Clarke's principle, with the heavy armour-plates in preparation for the "Northumberland," keep the mills in very active work. The forge consists of 10 steam hammers, capable of turning out all descriptions of wrought iron forgings up to 60 tons each piece. The bar mill rolls angle iron, flat, round, square, and all descriptions of heavy bar iron. The plate mill is capable of making boiler plates and ship plates up to 2 tons each plate; also fortification bars of equal weight. The armour-plate mill, rapidly approaching completion, will be the largest mill in Europe, and its capabilities will far exceed anything that has been hitherto attempted. This mill will be capable of rolling armour plates 12 inches thick, up to 20 tons each plate, as well as rounds and squares up to 18 inches. In order that these mills may be enabled to turn out a maximum quantity of finished iron ready for the market, a roughing mill has been erected to prepare the rough bars, tops and bottoms, &c., &c., necessary for the finishing mills. All the forgings in connection with the iron-clad frigate "Northumberland," as well as the heaviest of those for the "Minotaur," have been made here. The iron for the Inglis target, as well as the target itself, which stood so successfully at the late trial, was also manufactured in these works.

Centrifugal Pumps.—The following letter has been addressed to the Admiralty. As Mr. Colburn's report is nearly the same as that published on the 5th ult. in the *Engineer*, we may observe that circumstances have transpired which render it proper that the letter should appear in our columns:—"My Lords,—Trials of the large centrifugal pumps in the late International Exhibition were made early in November last by myself and by Mr. D. K. Clark. Mr. Clark has stated that "he acted for the Admiralty in the matter," and he has pronounced my report upon the trials to be erroneous. I deem it as much my duty as just to myself to state to your lordships that if Mr. Clark has made any report upon the trials in question, materially at variance with my own report (a copy of which has been laid before Colonel Greene, one of your lordships' officers), then such report by Mr. Clark is erroneous, and I hereby protest against its conclusions. I hold myself ready, on the production of such report by Mr. Clark, to point out the errors it may contain.—I am, my lords, your lordships' obedient, humble servant, Zerah Colburn, 76, Gower-street, Bedford-square, December 29th, 1862."—*The Engineer.*

Iron-clad Men.—It has been suggested in America, in view of the improvements which are daily carried out in iron-clad ships and batteries, that the same principal might be applied to their crews, or to infantry in the field. Some steps have already been made in this direction, and life-preserving vests have been sold, we believe, in great numbers. Why, then, can we not sheath the human body so that it will be perfectly protected, against rifle balls at least, and yet, at the same time, preserve its elasticity and activity unimpaired? The force of a bullet, stopped in mid career, would doubtless make the iron or steel-clad recipient wink, if it did not entirely destroy his centre of gravity, but we think most of our sharpshooters would gladly exchange the possibility of being stunned or even stricken senseless for a time, for the certainty of being killed outright without such protection. The ancient men-at-arms wore suits of mail, but they weighed down both horse and rider, and had to be abandoned. We ourselves know an Austrian inventor who was successful in making an india-rubber breast plate. He stood the fire of the old fashioned musket with safety, but found himself much bruised after the trials.

The Inventor of the Fire-escape, Abraham Wivell.—Wivell now took to scheming dreaming, some of his friends said. He proposed a plan for draining London independently of the Thames; for, said he, if all the sewers drain into the Thames. the Thames itself must become one great sewer. But this scheme fell to the ground; it was too far in advance of the times. His fire-escape was more successful; but, poor fellow, how sedulously he worked at his idea, and what time and money he spent before the design of his brain was embodied in tangible wood and iron! His first escape consisted of a rope, fastened in the inside wall of the upper storey of the house, and a belt, which was to be girded around the body of the person escaping, and was also to be attached to the rope. With such an apparatus Wivell frequently descended from the topmost room of his house, to the wonder of the surrounding neighbourhood. Although he had demonstrated the practicability of this plan of escape, people were slow to adopt it, and further thought led to the production of the well-known fire-escape, now happily found at the convergence of most of our principal London thoroughfares. Even after he had completed his escape, he could not, for a long time, get any help in bringing it out. But he was enthusiastic and persevering; and he at length succeeded in calling a public meeting, when he explained his plan in detail. The formation of a committee was the result of the meeting, and Wivell was awarded with the expenses of his escape, and—a gratuity of £10! Ultimately the Royal Society for the Protection of Life from Fire was formed, and Wivell's invention was adopted—*Social Science Review.*

Academy of Sciences.—The following are the prize questions proposed by this body at its last great annual meeting:—1. Mathematics.—To discuss with care the observations of tides made in the principal ports of France, and compare them to the theory (3,000f., papers to be sent in before the 1st of June, 1865); to re-examine the phenomena of capillarity, and compare them to the results of calculation (3000f., 1st April, 1864); to improve the geometrical theory of polyhedrons (3,000f., 1st of January, 1864); to establish a complete and rigorous theory concerning the equilibrium of floating bodies (3,000f., 1st July, 1864). 2. Mechanics.—To introduce some important improvement in the application of steam to the Imperial navy (6,000f., 1st of Nov., 1863). 3. Bordin Prizes.—On some questions of optics, at the candidate's choice (3,000f., 1st of July, 1864). To determine the direction and relative intensities of electric currents produced by various thermo-electrical substances (3,000f., 1st of July, 1864). To effect some improvement in the mechanical theory of heat (3,000f., 1st of July, 1864). 4. Natural Philosophy.—On the comparative anatomy of the nervous system of fish (3,000f., 1st of September, 1864). To study the changes effected during germination in the constitution of the tissues of the embryo and perisperm (3,300f., 1st of April, 1864). On the production of hybrid animals by means of artificial fecundation (3,300f., 31st of Sept., 1863). 5. Medicine.—To trace the history of Pellagra (5 000f., 1st of April, 1864). 6. Medicine and Surgery.—On the application of electricity to therapeutics (5,000f., 1st of April, 1866). 7. Surgery.—On the preservation of members by preserving the periosteum (the Academy offers 10,000f.; the Emperor also 10,000 f., 1st of April, 1866). 8. Bordin prizes of 3,000f. each, to be sent in before the 31st of December, 1863:—On the distribution of the vessels of the latex in the organs of plants; on the anatomical history of coral and other zoophytes of the same family; on the structure of the stems of plants, with a view to determine their respective families.

Trials of Mr. Bray's Traction Engine.—A series of trials was commenced on Tuesday last week in Woolwich dockyard with Bray's traction engine, in the presence of the Commodore-Superintendent and the officials of the yard. The engine is intended to supersede horse-labour for the ordinary work of the yard. It was exhibited in the Great Exhibition, where it was awarded two prize medals in classes 8 and 9 for practical utility. One of the boilers for the "Caledonia," weighing 28 tons, was placed on a truck, and attached to the engine, which drew it about the yard with perfect ease. The engine then went to the foundry, where a load, consisting of a plate weighing 16 tons 15 cwt., was drawn by it to the factory travelling crane, and here two other plates were put on the truck, each weighing about 18 tons, bringing up the load to over 30 tons. With this the engine went several times round the yard, turning the sharpest corners without any difficulty, with only one driving wheel in gear. The engine was then uncoupled, and run up and down the yard without any load being attached. The speed attained was equal to 10 miles an hour. It was tried over the rough paving, the soft ground, and the trams, and answered equally well on each. The day's proceedings terminated by conveying an old boiler, weighing 22 tons, from the foundry-yard to the iron-yard. On the following day the engine commenced by taking a load of about 20 tons of loam-plates from the foundry to the iron-yard. It had to take this load in and out and around the various iron stacks in the yard. This it did without any difficulty. It returned to the factory, and the sheer-legs were fitted to the engine, when it lifted the screw propeller of her Majesty's ship "Racer," which it took to, and brought back from, the weigh-bridge. The weight was ascertained to be 2 tons 1 cwt. 2 qrs. It then steamed on to the armour-plate shed, and drove, by means of the drum fitted for transmitting power, the hydraulic pumps used for working the press for bending the 4½ inch armour-plates for the "Caledonia," some of which were bent to the required extent by the power transmitted by the engine. Yesterday the experiments were continued, and the engine was tried as a steam fire-engine with equal success. The diameter of the cylinder is 7 in.; the length of stroke, 10 in.; the working pressure of the steam, 120 lb.; the gearing, 21 slow speed and 71 quick speed; the weight of engine complete, with fuel and water, is about 12 tons. It is fitted with link motion and reversing gear, feed and tank (hot and cold water) pumps, the latter being a double-action 5 in.

bore, worked direct from the piston through the cylinder bottom; Giffard's injector, sheer-legs, and a barrel for hoisting, a drum for driving machinery, a winch end for a fall rope or tackle, &c. The wheels and steering gear and general arrangement of the engine are on the company's patent principle, the steering being effected by means of a worm working in the segmental rack. The driving-wheels have inner and outer bearings, and the engine is mounted on inner and outer springs on each side of the driving wheels, while the fire-carriage is also mounted on a strong steel spring. The gearing is throughout of the best malleable cast-iron, and the driving wheels are of wrought iron. The machinery is cased in by a light iron casing, which at the end is formed into bunkers, wherein can be carried about 12 cwt. of fuel, while the tanks contain about 400 gallons of water. The engines and all the machinery are attached to a framing independent of the boiler, which is of the horizontal tubular description, made throughout of the best Lowmoor iron.—*Times.*

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 1705, 1713.
BOILERS AND FURNACES, 1734.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1730, 1756.
SHIPS AND BOATS, including their fittings, 1728, 1736, 1758, 1763.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 1731, 1732, 1744.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1716.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1707, 1708, 1715, 1719, 1723, 1726, 1738, 1741.
BUILDINGS AND BUILDING MATERIALS, 1704, 1714, 1727, 1757.
LIGHTING, HEATING, AND VENTILATING, 1718, 1721, 1722, 1729, 1751.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1703, 1709, 1706, 1737, 1742, 1753, 1759, 1760.
METALS, including apparatus for their manufacture, 1743. 1752.
CHEMISTRY AND PHOTOGRAPHY, 1712, 1717, 1724.
ELECTRICAL APPARATUS *none.*
WARFARE, 1710, 1754, 1761.
LETTER-PRESS PRINTING—*none.*
MISCELLANEOUS, 1701, 1702, 1711, 1720, 1725, 1733, 1745, 1747, 1749 1755.

1697. J. HEATLEY and J. TANGYE. *An improvement or improvements in lifting jacks.* Dated June 5, 1862.

The frame of this jack is rectangular in cross section, being made of bars or plates of iron rivetted together. In the said frame the ram of the jack, which is made in the form of a rack, slides. The bottom of the said ram or rack has a claw or foot which may be placed under the article to be raised. The said ram or rack is raised and maintained in its raised position in the following manner:—At the top of the jack a lever is situated, jointed by means of links to the upper end of the frame. The short end of this lever can be made to engage with and be disengaged from the teeth of the before-mentioned rack, the said end of the lever being rounded so as to fit in the said teeth. The short end of the lever being engaged with one of the teeth of the rack, its longer arm is depressed, and the rack or ram is raised by the said short end of the lever a distance equal to the pitch of the rack. The lever is then released from the rack, and its end made to engage with a tooth of the rack next below that with which it was first engaged, and the rack or ram is again raised, and so on till the article has been raised the required height. The ram or rack is maintained in its raised position after the disengagement of the lever from the rack, by means of a self-acting lever or catch below the raising lever. *Patent abandoned.*

1698. R. SILL. *An improvement or improvements in attaching direction cards, name plates, or other cards or plates to trunks, packing cases, and other articles.* Dated June 5, 1862.

In carrying out this invention the inventor affixes to the surface of the trunk or case or other article, a frame of thin metal, the said frame being, by preference, rectangular and closed on three sides. The said frame is attached to the surface of the trunk, case, or article, by means of screws, pins, or rivets. The direction card or plate is inserted in the open side of the frame, and is passed by a sliding motion into grooves in the frame, so as to fill up the open space in the frame. The direction, or inscription, or device on the card or plate is thus displayed in the said frame. The card or plate is prevented from being removed from the frame by means of a screw pin, which is passed through a hole in the middle of the open side of the frame, the head of the pin resting on the top of the frame, and being nearly flush therewith, and the screwed end of the pin passing through the part of the trunk or other article to which the frame is attached. A screw nut being screwed on the end of the pin, it is secured in its place, and the card or plate fixed in the frame. *Patent abandoned.*

1700. W. ROWE. *An improved forge and bellows.* Dated June 5, 1862.

This invention consists in the application to the bed plate of a forge of a supplemental or under plate, leaving a space between the two for the circulation of the air, in order to keep the under plate cool, and to prevent the top of the bellows from becoming burnt or injured by the heat of the forge fire above it. Also in the application of a supplementary or top-plate to the bellows, leaving a space for the circulation of air, so that the plate, when raised to its uppermost position, shall protect the upper plate of the bellows from injury by the heat of the forge. *Patent abandoned.*

1701. E. CONROY. *Improved machinery for cutting corks, bungs, and such like articles.* Dated June 5, 1862.

This consists in the use of a knife made to traverse horizontally on V guides by a crank and connecting rod, worked by the main shaft of the machine. Under this traversing knife the rough piece of cork is fed, and is supported by a bed and stop in the framing of the machine. The width of the strip to be cut off is determined by an adjustable stop, caused to traverse to and from the knife by a tappet, to allow the separated length to fall into a receptacle. The lengths to be cut into quarters are then subjected to the action of a number of revolving knives mounted upon a screwed shaft, having nuts or washers between the knives. The knives are caused to revolve with the shaft by a feather or projecting lip. The shaft is mounted in journals on the framing, and receives motion by gearing from the main shaft. To receive the length to be quartered, and to hold them during the action of the knives, a revolving bed is provided, and is supported in journals on the framing of the machine in front of the knives. The bed is provided with a comb-front for the passage of the knives through it, and receives a rocking motion from a cam on the knife shaft for throwing off the piece of cork which has been cut into quarters by the passage of the knives. The knives used for quartering may be differently mounted and actuated, so as to be free from the compressing action of the revolving knives. *Patent completed.*

1702. G. HADFIELD. *Improvements in the manufacture of casks or barrels, and in the machinery and apparatus to be used in the construction of the same.* Dated June 5, 1862.

This invention is not described apart from the drawings *Patent completed.*

1703. W. E. NEWTON. *Improvements in the construction of organs and other wind instruments, parts of which improvements are also applicable for regulating the pressure and flow of gas and air.* (A communication.) Dated June 5, 1862.

This relates, 1, to a novel construction or arrangement of parts, whereby the pressure of the air in the different parts of the instrument may be regulated. 2, To a novel or improved construction of single or double action pneumatic motor, applied to the keyboard or action of the instrument, for the purpose of rendering the power required to be exerted by the player to produce the notes. *Patent completed.*

1704. J. VERITY. *An improved composition for coating and preserving walls, or other exposed surfaces.* Dated June 6, 1862.

Here the inventor takes one bushel of quick or grey lime, which he mixes with 28 gallons of water, and, whilst the liquid lime is in a warm state, he adds either 20 lbs. of common salt, rock salt, or any analogous substance, which, after being well mixed and allowed to cool, is strained through a fine sieve; any of the ordinary colouring materials to produce the required shade may be added. The compound, when thus prepared, is ready for immediate use. *Patent abandoned.*

1705. E. DEATH. *Improvements in road locomotives or traction engines.* Dated June 6, 1862.

This consists, 1, in fixing the engine or engines on a bed plate connected to square plates at each end of the boiler, thereby obviating the present liability of the bearings and joints to become affected by the expansion of the boiler, and also admitting of the engine or engines being radially disconnected from the boiler when required. 2, In mounting the axle in two side plates, extending from end to end of the boiler, and fixed to the square end plates thereof, for the purpose of preventing the liability of the axles to become heated by contact with the boiler. 3, In forming the axle with journals working in bearings between the side plates and the wheels, which bearings are fixed to a frame extending the whole length of the engine. By this arrangement the said journals of the axle are made to form two pivots, in which the hinder part of the frame rests, when the front end of the boiler is raised or lowered by a screw and levers, or other lifting apparatus applied thereto. 4, In applying the power for turning a single steering wheel at or near to the axle, instead of above the top of the wheel, as usual. 5, In constructing the side or end framing, or both, in the form of hollow tubes, for the purpose of carrying water, so as to dispense with the use of a tank or tanks for the same purpose. *Patent abandoned.*

1706. G. DARLINSON. *Improvements in the manufacture of ribbons.* Dated June 6, 1862.

In addition to warp of the ordinary kind, which is used and woven together in the usual way, whether to produce a plain or figured ribbon, the inventor uses as part of the warp of the improved ribbons, whether plain or figured, a certain quantity of chenille or narrow velvet, either plain edged, or stamped. The chenilles or velvets are passed through the harness and sley of the loom, and are caused by the usual means to work into the fabric of the ribbon, or to float on the face of the same, or upon the back, or to become attached to its edge, as may be necessary to produce the effect desired, viz., a pattern produced by the appearance in the required places of the chenille or velvet on a pileless ground. *Patent abandoned.*

1707. W. R. JEUNE. *Improvements in the manufacture of fabrics suitable to be used as substitutes for solid leather.* Dated June 6, 1862.

Here the inventor takes a long sheet of fabric, felt, or paper; a strong calico, or a linen fabric, or a stout paper, he finds suitable. He spreads thereon a coating of india-rubber or gutta percha, or such like solution. The solution may be applied by a spreading machine, such as is commonly used in spreading india-rubber solution on fabrics to produce a waterproof material. When the solvent of the solution is evaporated by rolls, heated by steam or otherwise, a thin film of rubber or gutta percha is evenly deposited on the fabric, felt, or paper. He next applies a similar coating of india-rubber or gutta percha solution upon a number of skins or pieces of leather; and when the solvent is evaporated by the aid of iron rolls, he unites the skins or pieces of leather and fabric, felt, or paper, by passing them through the rolls with the prepared surfaces in contact, the rolls being so set as to press the skin or pieces of leather and the fabric, felt, or paper, firmly together. The fabric, felt, or paper, and skins, or pieces of leather, now united, are rolled upon a drum, and placed upon a machine in which, whilst the sheet is kept at the required tension, a knife running at a quick speed splits off as much of the skin or leather as may be required. *Patent completed.*

1708. A. V. NEWTON. *Improvements in knitting machinery.* (A communication.) Dated June 6, 1862.

The patentee claims, 1, a pad of india-rubber or other yielding material, applied and operating in combination with the needle ring or needle bar, and needles of a knitting machine, in the manner and for the purposes set forth. 2, The use in combination with the pad above mentioned of a second pad, so applied as to press upon the work just before the first mentioned pad leaves it, and continue holding it against the needle ring or needle bar while the first one is raised, as described. 3, The use in a circular knitting machine of a presser divided into two or more pieces or sections, having independent movements, substantially as specified. Lastly, the stop motion, composed principally or in part of slides suspended from the yarns, and a threaded rotating and longitudinal moving shaft or notched reciprocating bar, or their equivalent, applied in combination with the driving shaft and driving pulley of a properly organised knitting machine, to operate as set forth. *Patent completed.*

1709. W. HARDING. *Improvements in the manufacture of bonnet fronts, and in apparatus to be employed therein.* Dated June 7, 1862.

This invention has for its object the manufacture of bonnet fronts, with the view of producing the same at less cost and labour, as also to admit of the pattern or design being more advantageously varied than at present, and consists in causing the pleatings or gofferings forming the said fronts to be produced in a cold state through the medium of shapes or moulds of wood, metal, or otherwise, in such manner as to admit of the blond, lace, or other material, being conveniently threaded through, or passed round, the same, and held or retained in position suitable for being banded and finished in the ordinary manner. *Patent completed.*

1710. A. J. ADAMS. *Improvements in firearms.* Dated June 7, 1862.

The object here is to reduce the windage, and, at the same time, get a larger missile, or projectile, into the bore of a firearm of any calibre, and the patentee effects this object by a combination of ratchet wheels, or eccentric grooves, with rounded angles, and of angular grooves in the "lands," sometimes modifying the same combination by rounding all the angles. *Patent completed.*

1711. G. D. HATTON. *Improvements in presses.* Dated June 7, 1862.

This improved machine is an upright press for "nipping" or pressing purposes. The patentee uses two standards or upright pillars, with a broad foot to each, to give a firm support; these standards are attached at their summit by a cross beam, through which works a screw terminated by a lever and ball of considerable power, and supporting a plate which forms the upper flat of the press. The sides of the pillars are shouldered or grooved at distances of about 3 in. apart, commencing from near the base, and meeting the plate before named, at the greatest fall of the screw. A loose flat, or plate, of similar dimensions to the upper one before named, is placed upon one or other pair of shoulders, or grooves, of the standards or uprights according to the thickness of the matters to be pressed, so that the faces of the two plates enable articles of various thicknesses to be pressed by a short screw, and thereby avoid the loss of time and wear and tear of packing, or of causing a long screw to descend to the lower part of the press, when a thin substance is to be acted upon. *Patent completed.*

1712. G. HASELTINE. *A new and improved photographic camera.* (A communication.) Dated June 7, 1862.

The patentee claims, 1, a negative plate or bath holder, having a hollow journal, channel, and throat, constructed and operating substantially as and for the purposes described. 2, The hollow journal described for introducing and withdrawing the baths. 3, A double channel tubes and funnels, constructed, and operating substantially as, and for the purposes, described. 4, The combination of negative plate and bath holder, having a hollow journal and throat as one instrument, with the crooked stem funnel, constructed, and operating substantially, as described. 5, Giving the combined negative plate and bath holder the capacity of assuming horizontal and perpendicular positions at will, as described. 6, The combination of camera box, crooked stem, funnel, hollow journal, channel, and throat, and fluid tight holder, as described. *Patent completed.*

1713. C. HOOK. *Improvements in the construction of steam-engines.* Dated June 7, 1862.

This consists in forming an oscillating engine which regulates the introduction and omission of the steam or other motive power by the motion of the cylinder, thus obviating or avoiding the necessity of a slide-valve. To effect this, the patentee forms in the one bearing, or support of the cylinder, two passages connected with the steam pipe; and in the trunnions of the cylinder casts corresponding holes or passages, so that the apertures in the trunnions of the cylinder coincide with those in the bearing or support. In the opposite trunnion he forms two passages which serve as the exhaust, the waste steam after being used passing down the interior of the support to the exhaust pipe. The next part of the invention relates to the cock or valve which regulates the introduction of the steam to the cylinder. This he makes of a circular form, hollowed out on two sides, by which, when turned obliquely to the right or left. the steam is admitted or allowed to enter one passage of the cylinder, which admits the steam into the bottom of the cylinder, and urges the engine forward. To reverse the engine the cock is turned in the opposite direction, the steam is admitted through the opposite port into the cylinder, above the piston, which thus changes the direction. When the handle of the cock is turned quite straight, both passages are closed, and the engine will be at rest. *Patent completed.*

1714. J. Lovegrove. *Improvements in apparatus for inspecting small sewers and drains, and for facilitating the removal of obstructions therein.* Dated June 9, 1862.

In constructing, ventilating, inspection, or flushing shafts, at intervals, over small drains and sewers, they are constructed from the top of the sewer to the surface of the ground partly vertical, and partly curved, and also in two divisions, for a double shaft, so as to admit the passage of a bamboo cane (screwed together in short lengths) down one division of the shaft, turning into and along the sewer towards the outlet for any distance, and thereby effecting the removal of any obstruction between the shaft and the distance reached; also down the second division of the shaft, turning into and along the drain towards its terminal end for any distance. The shaft is covered with a marked box, adapted either for carriage or foot roadways, that can easily be opened, or lifted off, without breaking the ground. *Patent completed.*

1715. W. H. Turner. *Improvements in engines for carding cotton and other fibrous materials.* Dated June 9, 1862.

This consists in placing under the "licker in" cylinder a number of grate bars of varied angular shapes. The tops of these bars are formed so that, when in their places, they appear like the teeth of a circular saw inverted, but having spaces between them which gradually widen towards the bottom. At various intervals the bars are formed of different angles. *Patent abandoned.*

1716. A. Ford. *An improved method of protecting beer and other fluids from the direct action of atmospheric air.* Dated June 9, 1862.

Here the inventor places within a cask or vessel, or any appliance of any kind capable of protecting the beer or other fluid, a sac or cylinder of a light, flacid, waterproof material, or air-tight substance, having one end fixed to the corresponding end or head of the cask or vessel, and having one or more apertures corresponding to the bung hole, or tap hole respectively, the edges of such opening or openings in the sac or cylinder being elongated outwards, so as to overlap the edges of the corresponding opening or openings in the cask or vessel. The other end and sides of the sac or cylinder are to be fixed or not to the cask or vessel, as experience may determine, but calculated to fulfil the objects of the invention. He then places the fluid to be protected within such sac or cylinder, allowing the air admitted through an opening or openings in the cask or vessel to act only on the outer surface of such sac or cylinder, thereby adapting it to the contained fluid, and keeping up the necessary pressure to secure the due ejection of such fluid. *Patent abandoned.*

1717. E. Hottin. *Preventing stuffs and woodwork from igniting.* Dated June 9, 1862.

This composition contains three products, of which salt of tartar is the base, the two others being starch and sulphate of soda. *Patent abandoned.*

1718. J. Keeling. *Improvements in apparatus for the manufacture of gas.* Dated June 9, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1719 J. M. Ryo-Catteau. *Improvements in machinery for twisting wool, cotton, flax, silk, and other fibrous threads.* Dated June 9, 1862.

To effect the objects of this invention, the patentee mounts on a frame or stand a spindle carrying the cotton or fibrous material to be twisted, to which he communicates a rotating motion by a drum connected with it by a band. By these means he gives the thread the first twist; after leaving the reel or bobbin, the thread is passed between two drawing cylinders or rollers, over one of which the thread is wrapped; from these cylinders, if cotton is being twisted, the thread passes under a roller immersed in water (if silk or wool, this is omitted), then through a guide, from which it passes to the second bobbin or spindle, similarly formed to the other, but placed vertically, and revolving in a different direction, which gives the thread a second twist. This bobbin is moved up and down on its spindle by an eccentric on the main axle, for the purpose of winding the thread regularly and evenly. The rotation of the last bobbin is regulated by a small-grooved pulley placed beneath it; in the groove of this pulley, and partly enveloping it, is a cord with a weight attached to it, and by causing the cord to embrace more or less the circumference of the pulley, and thereby increasing or diminishing the friction, the tension of the thread as it is wound on the bobbin is determined. By this arrangement the thread is twisted with greater speed and perfect regularity, neither are the colours liable to be mixed, but remain perfectly distinct and visible after the twisting. *Patent completed.*

1720. C. W. Heckethorn. *Improved apparatus for obtaining and applying motive power.* Dated June 9, 1862.

Here the inventor proposes to attach to a shaft a series of hollow spokes, to the closed ends of each of which a bellows is fixed, the upper or moveable plate or cover of the bellows being weighted with metal. The bellows communicate with the hollow spokes by suitable openings at the places of attachment, and the hollow spokes communicate with each other by an opening through the shaft. The apparatus is to be placed in a reservoir of water, the shaft being set in bearings some distance below the surface of the water, when it will be found that the weights on the bellows will force down and close the covers of those in a vertical position, and will open or separate those bellows on the opposite spokes, which would then be in a contrary or inverted position, the effect of which would be that the closed bellows would expel the air through the spokes into the opposite bellows, thus causing the series of inflated bellows on one side of the shaft to rise in the water, while those on the opposite side, being shut, would sink. When the spokes of the ascending bellows have just passed their highest point, and are in the act of descending, their weights in turn being uppermost, press down the bellows, which sink in the water, aiding those on the opposite side to ascend. By these means a powerful rotary motion is communicated to the shaft, and by placing suitable gearing thereon, the power thus obtained may be applied to machinery or other purposes. *Patent abandoned.*

1721. F. Giachosa. *Improvements in ventilating mines, ship's holds, and other places.* Dated June 9, 1862.

The object here is to facilitate the removal of carbonic and other obnoxious and deleterious gases or vapours from mines and other places. For this purpose, the patentee uses chambers formed by covers and diaphragms or partitions, the surface of which are combined by cylinders of leather, or other suitable flexible material. The bottom of the chamber, or the lower of a series (when a series is employed), is connected by a cylinder of leather or other suitable flexible material, to a bell-mouthed collector, adapted to collect or admit of the flow of the gases from the lowest surface where such apparatus is applied. Motion is given by suitable mechanism to the diaphragms or partitions to the chambers, or to one of them, to effect the alternate expansion and contraction of the chamber or chambers for the reception of the gases, and for their being forced upwards by suitable passages, in connection with such chamber or chambers. *Patent completed.*

1722. A. J. Joyce. *Improvements in lighting and heating.* Dated June 9, 1862.

This invention consists in enclosing or encasing lamps, furnaces, and apparatus for effecting combustion, whether for the purposes of lighting or heating, in a chamber case or vessel containing and supplied with compressed air, and furnished with ingress and egress valves, for allowing of the introduction of fresh compressed air, and of the escape of such portions of the compressed air as may be necessary. The patentee places the ingress valves, by preference, at bottom, and the egress valves at top, but always under such conditions that the compressed air shall pass first through the fuel to feed its combustion, and afterwards through, round, or over the ores, crucibles, boilers, or other matters that have to be heated, finally escaping by transit through a water cistern, and he weighs them according to the pressure required to be maintained. *Patent completed.*

1723. A. Knowles. *Improvements in apparatus for washing extracted wool and other fibre.* Dated June 9, 1862.

For the purposes of this invention, the patentee employs a wooden vat, having a false bottom of perforated metal, and furnished with suitable pipes or passages, so that water may be caused to flow continuously through it. In order to agitate the contents of the vessel, and to keep them in motion, three, or other convenient number of axes are mounted horizontally over the top of the vessel, and transversedly to the length thereof. A series of bars descend from these axes and dip into the vessel, where they act as stirrers, the axes carrying them receiving a vibrating motion from a crank, or in any other convenient manner. The two axes near the ends of the vessel are connected with the crank, or other instrument, so as to move in unison, but the central axis has a reverse action communicated to it, the connection with the driving power being made above the axis, in place of below, as is the case with the other axes. This method of working the agitators causes their action to be very complete. The ends of the vessel are lined with plates, which curve inwards at the top and bottom; this form is given to them to assist the circulation of the liquid in the vessel, and prevent it being driven over at the ends by the action of the agitators. *Patent completed.*

1724. W. Smith. *Improvements in photography.* (A communication.) Dated June 10, 1862.

This invention relates to the ornamentation of photographic works, and chiefly to the production of back grounds, borderings, and such like aids to the art of photographing objects. For these purposes the inventor produces the design required by employing a sheet of glass, or other equivalent transparent substance, upon which, by galvanic agency, he deposits, first, a coat of gold or other metal suited for the purpose, and next a coat of platina or other equally suitable metallic surface. He then engraves, by means of a still or point, the required ornamental design, so that light may pass through the lines so marked, engraved, or cut into or through the metallic surface. An open space may be left in the centre or other part or parts of the plate prepared, as described, so that a portrait or portraits, or other subject or subjects, intended to be reproduced may be introduced behind or before such space, or otherwise in combination with such engraved plate. *Patent abandoned.*

1725. T. Lister. *Improvements in the material to be employed for address cards, visiting cards, labels, railway tickets, &c.* Dated June 10, 1862.

This invention consists in the application or employment of sycamore, beech, holly, or other suitable kind of wood, cut into thin slips or shavings, to any convenient size and form, as may be required for address cards, visiting cards, labels, railway tickets, and other similar purposes, whether for printing or writing upon, as a substitute for paper, card-board, or other material usually employed for such purposes. *Patent abandoned.*

1726. J. Kinlock and T. Edmeston. *Improvements in looms for weaving.* Dated June 10, 1862.

This invention relates to an improved mode of regulating the yarn beam, so as to give the necessary equal tension to the yarn as the beam varies in diameter, and consists in fixing a cam or eccentric on the crank shaft of the loom; the cam or eccentric acts upon an arm, or lever, connected by a rod to a sliding stud, which slides downwards on a quadrant lever as the yarn is taken off the beam in the process of weaving. The said quadrant lever is a portion of a clip or strap passing round a pulley, and is tightened so as to maintain the requisite friction by means of a screw passing through the ends of the clip, the pulley being secured on the end of a small shaft, carried by a fixing on the loom side, instead of the original fixing for carrying the yarn beams. The end of the shaft is hollow, into which the pivot of the yarn beam is placed, and is carried by it. At the end of the beam is fixed a flange, in the outer surface of which are cut two slots or holes, a similar plate or flange being fixed on the small shaft, with two studs extending into the slots or holes, thereby securing the yarn beam to the small shaft, and also enabling it to be easily taken out and replaced. The small shaft is caused to oscillate by means of the cam or eccentric fixed on the crank shaft through the aforesaid clip, the cam or eccentric being fixed so as to relieve the yarn when the stud is open, and close it when the stud is closing. The sliding stud is attached to a lever by a rod passing down at the end of the clip, which lever is carried by a fixing secured to the clip; the other end of the lever is pressing against the yarn beam by the preponderance of the rod and sliding stud, and, consequently, moves downward as the yarn beam diminishes in diameter, thereby increasing the stroke or oscillation of the beam as required. The lever being attached to the clip, there is no friction at the point where the lever presses on the beam, as all parts oscillate from the same centre. The yarn is also allowed to pass along through the clip by the pulley slipping round, and the clip is a more regular friction than the present plan of weights and ropes. *Patent completed.*

1727. J. A. Pols. *An improved method of refining oils.* Dated June 10, 1862.

In the case of rape, olive, or cotton seed oil, the patentee mixes with it American potash, quick lime, and white vinegar, to a strength of 36 degrees Beaunie. After subjecting the oil to this solution, it is filtered through charcoal, sawdust, and salt. By this process the patentee produces a good oil for burning. For machine oil he uses a solution of chloride of lime of the strength of 20 degrees, with 2½ to 3 degrees of sulphuric acid. By this process, after filtration, he produces a bright oil, free from grit, and not to be affected by cold. *Patent completed.*

1728. N. Davis. *An improved propeller for ships or vessels.* Dated June 10, 1862.

This invention consists of a horizontal propeller to be worked at the sides of ships, and is composed of a series of oars or paddles united by a frame. To retain its horizontal position this propeller requires double shafts, to which it is adjusted by cranks, and the whole is to be protected by a box of proportionate size. The horizontal propeller, the paddles of which can be increased in number according to the length of the ship and force of the engine, enters the water nearly perpendicularly, and emerges from it in the same way. In every revolution it is submerged, and then rises above the water. In the former position it gives the impetus to the vessel, and in the latter the vessel is left partly to exhaust the speed imparted to it, without meeting with the peculiar obstructions which are known to exist in the rotary paddle and in the screw now in use. *Patent abandoned.*

1729. G. T. Jourdain. *Improvements in treating cocoa-nut oil.* Dated June 10, 1862.

According to this invention, cocoa-nut oil is boiled in water, in which is cyanide of potassium, or of sodium, or of calcium and such boiling is continued till the oil is deprived of smell. The whole is then allowed to cool and settle; the oil is then separated from the matters which settle from it, and washed. *Patent completed.*

1730. H. C. Jennings. *Improvements in the preparation of skins for driving bands and harness traces.* Dated June 10, 1862.

The hides or skins are, according to this invention, to be deprived of hair by the usual means employed by tanners, or by solutions of caustic soda or potassa. The pelts or dehaired skins are now to be pared and rendered smooth upon the flesh side, so as to make every part of equal thickness, and are now to be steeped for two days in a solution of soda ashes, or of crystals of soda of commerce, or of pearl ashes, the solutions to be saturated with the above-named carbonated alkalies, at the ordinary atmospheric temperature, and they must remain in the solution until perfectly impregnated, and swelled to the maximum thickness; after this, the skins must be drained for a few hours, and then immersed in a saturated solution of sulphate of iron, with about 2 or 3 per cent. of sulphuric acid; when the iron liquid has penetrated completely into the skins, they are to be soaked in a solution of carbonated alkali, until the sulphuric acid of the iron solution is decomposed, and again to be returned to the solutions of iron, and so on, alternately changing the skins from the alkaline solution to the ferruginous solution, until the skins become firm and solid, and the whole of the gelatine is transformed into an insoluble substance. This object attained, the skins are to be wetted with the alkaline solution, and then steeped in a mixture of rosin oil, rock oil, paraffin oil, or naphtha, or any liquid hydrocarbonate, and in which has been dissolved 15 per cent. of gum, colophane, or resin, frequently turning and moving the skins to insure the penetration of the oily composition. When a perfect combination has been effected, which will depend upon the thickness of the skins or hides, the skins or hides are to be dried in the air, and when dry are to be rubbed or pressed with a mixture composed of equal parts of boiled linseed oil and turpentine. The skins are now to be cut into strips or bands, of the desired breadth, and are to be rolled or pressed to condense and equalize the substance. Before the bands are sewn or rivetted into lengths, it will be advantageous to rub into the surface a mixture of soft soap and cod or neatsfoot oil, to give the bands the proper degree of suppleness, without, however, producing too great elasticity by employing too much of the mixture. *Patent completed.*

1731. J. Alison. *Improvements in harrows.* Dated June 10, 1862.

In constructing harrows, according to this invention, a series of parallel axles are applied at each end of a suitable frame. Each of these axles carries rows of radial tines, which, at their lower ends, penetrate the surface of the land. These axles are alternately held from rotating, and are then permitted to rotate a distance so that another row of the teeth of each axle may come into action, whilst the row of tines of each axle, which has been in action for a time, comes out of action, and deposits any accumulation which has taken place on such tines. This periodical changing of the tines of the several axles may be accomplished in several ways, but it is preferred that inclines should be applied to the side of one of the wheels of the implement, which are caused to act, from time to time, as the wheel rotates on a lever, which is in connection with stops applied, in suitable positions, to retain the tines on the several axles from rotating till such stops are removed out of the way. These stops then again come into action, after allowing the rows of tines which have been in action to pass, in order to stop the next rows of tines and their axles from rotating till the points of those rows of tines have been for a time drawn through the surface of the land. It is preferred that the frame of this harrow should be so arranged as to admit of two rollers being interposed between the set of axles with their radial tines at one end of the machine, and the set at the other end of the frame, and also to admit of drilling apparatus being interposed between the two rollers. *Patent completed.*

1732. J. B. Ingle. *Improvements in reaping and mowing machines.* (A communication.) Dated June 10, 1862.

This invention relates to sweep rakes in harvesting machines which traverse on a vertical axis behind the cutter bar, and have crank arms, which turn in horizontal bearings, for the purpose of lifting the rake and holding it above the grain, while it is moving forwards towards the cutters. The first part of the invention consists in communicating motion to the rake mechanism from the main driving shaft, or other suitable shaft of the machine, by means of a yielding clutch, so arranged by a combination of inclined teeth on the moveable part of the clutch, with a pin or pins, or opposite inclined teeth, fast to the driving shaft, and a spring to keep the two parts of the clutch together, that the clutch only operates to move the mechanism of the rake when the harvesting machine is drawn forward, the rake ceasing to operate when the machine is backed. The second part of the invention consists in communicating the traversing motion of the rake to the vertical turn post or traversing axis of the rake, from a crank turning on a horizontal axis, and geared to the main driving wheel by means of two connecting rods jointed to each other by a compound or universal joint, one of the rods being connected to the wrist pin of the driving crank, and the other to the horizontal arm of the vertical turn post, the end of the latter rod extending through an eye guide in which it plays back and forth with sufficient freedom to admit of the gyration of the crank end substantially, as described. The third part of the invention consists in combining with a rake arm, supported by, and turning in, horizontal bearings in a horizontal traversing arm, vibrating on a vertical axis, a lifting arm, projecting from the rake arm, a stop placed on the back part of the frame of the machine, and a self-acting, holding, or rotating mechanism attached to, and traversing with, the rake arm, and independent of the main part of the machine, substantially as described, for the purpose of lifting the rake at the end of its back motion after it has discharged the grain from the platform, and sustaining the rake in an elevated position above the accumulating grain on the platform while moving forwards towards the cutters. And this part of the invention further consists in tripping the latch by suitable means at the end of the forward motion of the rake towards the cutters, for the purpose of permitting the rake to descend to the platform at the proper time to commence raking, substantially as described. The fourth part of the invention consists in driving a sweep rake from the cutter bar shaft of a harvesting machine, by means of a worm on the cutter bar shaft, a worm wheel carrying a crank and rotated on a vertical axis by the worm wheel on the cutter bar shaft, and a connecting rod from the horizontal traversing arm which carries the rake to the wrist pin on the crank carried by the worm wheel or their equivalents, substantially as described. *Patent completed.*

1733. J. G. Appold. *Improvements in regulating the discharge of water and other liquids and air and other gases.* Dated June 10, 1862.

This invention relates to a novel arrangement of automatic apparatus, whereby the rate of discharge of water, air, or other fluids, supplied at varying pressures, may be equalized or made nearly uniform. This result the patentee obtains by mounting in a suitably shaped chamber, through which the water or other fluid is passed, a swing valve, the movement of which (under the excess of pressure of the water), from its vertical position, will contract the discharge passage, and thereby limit the discharge of water. *Patent completed.*

1734. J. Shand and S. Mason. *Improvements in steam boilers.* Dated June 11, 1862.

This invention relates to improvements in the construction of boilers or steam generators (applicable to steam fire-engines), such as described in the specification of a patent granted to the present patentees, dated April 11, 1831 (No. 889), wherein an external and internal cone are employed, the latter forming the fire-box and chimney. The patentees have found in practice that the upper part of the internal cone which passes through the steam space is liable to be over-heated, and the object of the present improvements is so to modify the upper part of the internal cone or chimney that the over-heating may be avoided, the extreme heat being transmitted to the water as it is supplied to the boiler. For this purpose they prefer to contract the internal cone or fire-box below the water line of the boiler, and above the horizontal annular tube, through which the hind axle passes (when the boiler is intended for a portable steam or fire-engine), so that the upper or contracted part of the internal fire-box forms a parallel tube, or nearly so. The contracted part of the chimney of the fire-box is surrounded by a casing which forms an annular space ascending near to the top of the boiler; into this space the feed-water is forced, and when full it flows over into the boiler. *Patent completed.*

1735. W. Lennon. *An improved safety stirrup.* Dated June 11, 1862.

The documents relating to this invention cannot at present be seen, an extension of time for filing the final specification having been granted.

1736. J. D. Wake. *Improvements in the construction of ships and vessels.* Dated June 11, 1862.

This invention consists, 1, in constructing ships with double or single wooden floors, with iron ribs or frames of T iron, or double angle iron riveted back to back to form T iron, also with reverse angle iron where required for ceiling. 2, In uniting the iron ribs to the wooden floors by either inserting them underneath the bottom of the floor of the double angle or T iron rib, or by bringing the ribs alongside of the floor, one side being underneath the floor, and acting as a shoe at floor heads, bolting the rib or frame to the floors either up and down or sideways, as convenient, the ribs or frames extending underneath the floor, and meeting in the centre line, and joining the two ribs or frames by a plank riveted together. 3, In the employment of a longitudinal iron plate as a sheer streak outside the frames from stem to stern, and an iron plate along the floor heads outside to connect the diagonal bracing. By these means the patentee entirely dispenses with all vertical timbers between the skins of the vessels. *Patent completed.*

1737. H. Bland. *Improvements in sewing machines.* Dated June 11, 1862.

This invention consists, 1, in constructing sewing machines horizontal instead of vertical, that is to say, the work to be sewn is held vertical, whilst the needles pass horizontally through same, and is designed especially for sewing leather or other material edge to edge, without turn-down or seam. The patentee proposes to use two needles, one at each side of the machine, so disposed as to cross each other at an angle in passing through the work. Each needle-holder slides freely between guides, and turns on a pivot, so that, as each holder aforesaid comes into contact with a small roller, the needles will be pushed forward, and thus advance the work another stitch forward, and so on in succession. In connection with the foregoing parts the patentee proposes to employ a "looper," or hook, to extend the loop and insure its passing the point of the opposite needle. 2, In constructing sewing machines upon the principle lastly above described, but vertical instead of horizontal, and in adapting thereto a simple feeding apparatus worked by a cam on the main driving spindle of the machine. The aforesaid feeding mechanism works between collars on the main driving spindle, and the length of stitch may be adjusted by a pin passing through a slot in the feeder rod; both needles are worked by one cam. 3, In constructing sewing machines, as follows:—He employs two straight needles, each connected to a holder, also connected to bent or curved arms or levers jointed together, one extending above the bed-plate of the machine, and the other below the said bed-plate, so that each needle in passing through the work to be sewn describes an arc of a circle; but as the point of each needle inclines outwards, it follows, therefore, that after said joints have passed through the work, and in consequence of each needle being inclined, the effect is to cause the said needles to press or force the work forward or away from the points of the needles, and thus the needles become feeders of the work thereto. He proposes, in conjunction with the above, to employ a holder for keeping the work steady as the needles pass through same. An important feature in this arrangement consists in attaching the aforesaid curved arms of the uppermost needle-holder to the outside of the bed-plate of the machine, and in so curving or bending the same that their opposite ends meet together at the centre of the said bed-plate, where they are connected together and to the needle-holder, which may be adjusted to any desired angle by a thumb-screw. A screw may also be employed to adjust the lowermost needle-holder and needle. The several parts are operated upon by a cam. If desirable, an ordinary feeding-bar may be employed, and worked in conjunction with the needles for advancing the work. Lastly, these improvements relate to a new and improved mechanical arrangement or contrivance for regulating or adjusting with certainty the proper degree of tension upon the sewing material employed. *Patent completed.*

1738. W. Holland. *Improvements in carding engines.* Dated June 11, 1862.

In carding engines it has been heretofore customary to employ a large sheet metal or tin trough to guide the fleece from the doffer to the cylinder rollers or drawing box, and the trough, as it has been heretofore employed, is found to be expensive and inconvenient. Now this invention consists in dispensing with the trough above referred to, and in guiding the fleece from the doffers to the calendar rollers or draw box by means of a simply shaped, less expensive, and more effective instrument, consisting of a guide plate placed before the calendar roller or draw box. When a trumpet-mouth or funnel is used, the patentee attaches the guide thereto, but when trumpet-mouth or funnel is used the guide may be fixed by means of brackets or other fixings to the carding engine in any convenient manner. The object to be attained by the use of this guide or guide plate is to cause the selvages of the fleece to curl on leaving the doffer, and thereby prevent the jagged edges of the fleece from falling down, which has not hitherto been effectually done. To effect this object he makes the guide or guide plate of a rounded or segmental shape in the centre, with protuberances or horns at each side, forming recesses (as shown in the drawings), and thereby causing the selvages of the fleece to turn in or curl under before the fleece reaches the calendar roller or draw box. *Patent completed.*

1739. W. Crook. *Improvements in looms for weaving.* Dated June 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1740. D. Crickton, W. Doubavaud, and D. Crichton. *Improvements in looms for weaving.* Dated June 11, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

1741. J. Marsh. *Improvements in the manufacture of lace.* Dated June 11, 1862.

The object of one part of these improvements is to obtain various ornamental effects to lace, by causing holes or parts of the fabric to incline or otherwise diverge from, or to be at angles to, the selvage thereof by the use of additional warp threads forming part of the fabric, or which may be used as temporary lacing threads, such additional warp threads being caused to pass through from one side of the fabric to the opposite, and there change relative position with other of the threads if desired, and their return by another hole or mesh. *Patent abandoned.*

1742. J. H. Johnson. *Improvements in cradles or swing cots.* (A communication.) Dated June 11, 1862.

This invention relates to a mode of rendering cradles or swing cots self-oscillating, and consists in applying to one or both of the standards or supports a clock mechanism, consisting of a barrel spring, which imparts motion to a revolving eccentric pin through a pair of spur wheels. The eccentric pin works in a suitable opening or slot in an escapement lever, which transmits the oscillating motion to the body of the cradle or cot so soon as the spring is wound up. Provision is also made for disengaging the clock mechanism when desired, and a stop or pin is used for stopping the oscillations when the cradle is required to be at rest. *Patent abandoned.*

1743. B. W. Gerland. *Improvements in the manufacture of sulphate of copper.* Dated June 11, 1862.

This invention relates to a process for obtaining sulphate of copper in a comparatively pure state, and also other substances (cobalt, silver, nickel, and uranium) from solutions of copper ores, or other compounds of copper. In order to carry out this invention it is necessary to convert the copper of the material used with sulphate of copper, if it does not already exist in that state. It is, in most cases, convenient to extract the copper and other metals from the ores or other compounds while in their native state, or, after some preparation with muriatic acid, by which means solutions are obtained containing the chlorides of silver, copper, cobalt, nickel, and uranium, together with, more or less, impurities. *Patent completed.*

1744. J. E. Holmes. *Improvements in machinery for cultivating or harrowing land.* (A communication.) Dated June 11, 1862.

The prongs or teeth of this harrow are, by preference, curved at their points, and are arranged radially round central bosses, which are mounted loosely on horizontal shafts, that are set diagonally, or at an angle, to the line of draught. Any convenient number of these sets of radially-arranged teeth, tines, or prongs, may be mounted on the diagonal shafts, and, from their position, the very act of drawing them over the surface of the land will cause them to rotate on their axes, and, in so doing, the weight of the implement will cause the points of the teeth, tines, or prongs, to dig into the ground, and tear up the same, and with it any weeds with which the tines may come in contact. The diagonal shafts are set at opposite angles, and, at one end, are brought nearly close together, while the other ends diverge, and are held in position by a segmental bar. The implement is drawn forward by a loop, hook, or eye, placed near the apex of the angle formed by the meeting of the two diagonal shafts. In order to take any undue strain off the diagonal shafts, the draught hook, or eye, is attached to a central draught bar, which extends from the front to the segmental bar at the rear of the implement. Fixed broad shares, cutters, scarifiers, or other analogous tools, may be adapted, if desired, to any convenient part of the draught bar, or the segmental bar. *Patent abandoned.*

1745. J. Hetherington. *Improvements in lubricating revolving surfaces.* Dated June 11, 1862.

This invention refers to an arrangement in which the lubricating material is carried within a chamber formed in the revolving part, and consists in arrangements whereby the patentee is enabled to renew the supply without the removal of such revolving part. For this purpose he adapts thereto a tube which revolves with it, and projects inward towards the centre of motion, so that the surface of the lubricating material is kept below the orifice thereof. Or, according to another plan, he forms a communication with the chamber through the shaft, which communication is capable of being closed by a screw, plug, or equivalent apparatus. *Patent completed.*

1746. J. Ingham and W. P. Wood. *Improvements in preparing colouring matters for dyeing and printing.* Dated June 12, 1862.

This invention consists in mixing red analine dye with caustic soda, or any other alkali (except analine), and subjecting the same to heat until blue or violet colour is produced, as required. The mixture or compound is then dissolved in spirits of wine, or any other suitable solvent. *Patent completed.*

1747. T. Spright. *Improvements in horse hoes.* Dated June 12, 1862.

This invention relates to a previous patent, dated 22nd Sept., 1859 (No. 786), and consists in suspending the shaft or bar to which the hoes are attached upon a bearing at its centre, instead of at each end, so that, when one end is raised by turning a handle or otherwise, as described in the specification of the former patent, the other end is lowered in a corresponding degree, and thus, when working over ridged or curved surfaces, or along what are called "lands," the depth or bite of the hoes may be regulated by the attendant with the greatest nicety. *Patent abandoned.*

1748. F. Tolhausen. *A new or improved surgical injecting apparatus.* (A communication.) Dated June 12, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1749. A. A. Lerenard. *Improvements in cement or mastic for making joints of steam, water, or gas pipes or chambers.* Dated June 12, 1862.

The patentee claims, 1, employing india-rubber, more or less vulcanized, to make a cement or paste fit for making joints of steam, water, or gas pipes, by combining and mixing, by a suitable trituration, the vulcanized or non-vulcanized india-rubber, in various proportions, with powdered mineral or earthy substances, among others, and especially with a powdered hydraulic cement, fire-clay, and flowers of sulphur. 2, The formation of sheets of various thicknesses by mixing in the cement some hemp or other textile material cut in small pieces, and cutting rings, square bands, or strips from the said sheets for making joints. 3, Using the same cement in a softer or more liquid state, that is to say, containing less powdered hydraulic cement and sulphur, to make joints with strips of hemp doubled up or coated with this india-rubber solution. *Patent completed.*

1751. H. S. Firman and W. J. Williams. *Improvements in lamps more particularly designed for burning paraffin or coal oil and other hydro-carbons of different grades, or any combustible material used for obtaining light.* (A communication). Dated June 12, 1862.

This consists, essentially, of a lamp body of the usual or other form, in the top of which is firmly fixed a block, through which the wick tube passes so loosely that it may be slipped up or down, yet sufficiently tight to retain its position. The block is surrounded by a conical case, which is surmounted by a dome-shaped deflector, the case being perforated with holes at the bottom, and the base of the deflector being also perforated. Between the case and the block is interposed any substance that is a slow or non-conductor of heat, but, by preference, a block of wood, which is intended to prevent the wick tube from becoming too much heated, and thus conducting caloric down into the oil, thus increasing the evaporation. This arrangement also tends to diminish the danger of explosion should the oil in the lamp be of an explosive nature. The inventors secure the deflector or chimney, or both, to the cap or top of the lamp by a spring. *Patent abandoned.*

1752. A. Salviati. *An improved mode of producing indestructible inscriptions and ornamental surfaces in gold and other precious metals.* (A communication.) Dated June 12, 1862.

These ornamental surfaces are composed of a combination of glass, enamel, or vitreous materials, with thin sheets of gold and silver, or both. According to one modification, the patentee takes a thin sheet of metal, either gold or silver, and having heated in an oven the piece of glass to be ornamented, so that it may be softened, he places the thin sheet of metal thereon. Or the thin sheet of metal having been laid on a table, the piece of glass having been previously softened by being heated in an oven, is brought nearly into contact with the metal, which will immediately attach itself to the glass, and then upon applying a very thin sheet of glass to the metal surface, the latter will be protected by a vitreous coating. *Patent completed.*

1753. B. George. *Improvements in the construction of portable beds, bolsters, pillows, and sofa and other cushions.* Dated June 12, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1754. W. Jackson. *An improved shield for the gums, to protect them from injury when cleaning the teeth.* Dated June 12, 1862.

This consists in the use of a thin metallic plate, which is made to fix over the gums close up to the necks of the teeth, leaving the whole enamelled surface of the teeth exposed. A separate plate is fixed to the upper and lower jaws, and the plates are kept in place when in use by spring attachment or otherwise. *Patent completed.*

1755. W. Smith. *Improvements in apparatus for cutting or dividing soap.* Dated June 13, 1862.

This consists in the combination of a stationary grooved stage or rest for the soap intended to be cut or divided, with a moveable frame working on moveable or fixed centres, and containing a set of adjustable knives or cutters. The stage or rest is fixed on a horizontal table, by preference in an inclined position, and the grooves are formed therein at suitable distances apart. The moveable frame, which carries the cutters or dividers, has its centres of motion also fixed (or by preference moveable), to the horizontal table, and is worked by a handle at the end opposite to such centres of rotation. The cutters or dividers consist of wires tightly stretched and fixed in the frame or blades, corresponding in number and relative distances apart with the grooves in the stage or rest. The adjustment of the cutters or dividers is effected by slots in the frame and tightening screws, or by other means. *Patent abandoned.*

1756. G. Haseltine. *Improvements in the construction and application of rails for railways.* (A communication.) Dated June 13, 1862.

The nature of this invention consists in dividing the metal used in making the ordinary single bar flange rail into two parts, which may be termed the "wearing rail" and the "supporting rail," and combining them together in distinct horizontal planes, or parallel with each other, by means of intermediary plates or blocks, in combination with clamping hooks, or their equivalents, arranged and secured at equal distances apart from each other, and also in such uniform relation to the previously determined distances apart of the cross ties or ground sills used for the foundation of the said combined rails, so as to bring the points of attachment, or application to the cross ties or ground sills, at such parts only of the supporting rail as will be mid-way between each pair respectively of the said combined plates and clamps. The invention further consists in securing each of the joints which occur at the abutting or contiguous ends of the said "weaving rails," by a longer intermediary plate, in combination with clamping hooks, or their equivalents, the said plate being arranged along between the supporting rail and the abutting or contiguous ends of the "wearing rails," so as to be together with the said joint midway between two adjunct cross-ties or ground sills, for the purpose of giving to this part of the track the same general elasticity, and at least the same equality of strength, which are characteristics of the other portions of the same. *Patent abandoned.*

1757. A. Longbottom. *Improvements in the manufacture of artificial stone.* Dated June 13, 1862.

This artificial stone is intended for cleaning and scouring, and other household purposes. It is composed as follows:— For every hundred parts of the compound, the patentee takes sixty parts by weight of the ordinary dehydrated sulphate of lime or gypsum; to this he adds twenty parts of oxide of calcium or caustic lime, ten parts of steatite, and ten parts of zeolite; or, by preference, eight parts of silica and two parts of hydrate of sodium. These substances are to be intimately blended by trituration, in any convenient apparatus. Water is now added in a sufficient quantity to form it into a plastic or semi-fluid mass, suitable for moulding it into any desired shape. The moulded compound when dry is white, but a colouring matter may be added. *Patent completed.*

1758. J. Wilson. *Improvements in the construction of ships for war purposes, applicable also to the mercantile marine.* Dated June 13, 1862.

Here the patentee arranges wood and iron or steel in alternate layers, either horizontally, diagonally, vertically, or otherwise, so that the force of the blow of a projectile shall not impinge against the side of a metal plate, but against the edge thereof. He proposes also, at a certain distance below the water line, according to the power of the projectiles to which any vessel might be exposed, to place and bolt firmly together alternately plates of wood and iron or steel, either horizontally to the keel of the ship, or perpendicularly to it, as may be found most advantageous. In either case it is not the side of the plate which could be subjected to the blow of a projectile, but the edge, and this constitutes the essential feature of this invention. He also proposes to place over all an external plating of iron and steel, so as to distribute the force of the blow over several of the iron or steel plates. *Patent abandoned.*

1759. J. H. Glew. *Improvements in sewing machines.* Dated June 13, 1862.

This relates to sewing machines in which two needles and two shuttles are employed, and consists in an improved arrangement of placing the shuttles, and employing a web or vertical plate in the middle of the shuttle race. The patentee places the shuttles face to face on each side of the web, by which means two rows of stitching can be obtained much closer than by any other method, the web being employed to form part of the guide or race for each shuttle. *Patent completed.*

1760. C. A. Tyler. *A new or improved holder for holding dinner and other plates and dishes, and for other like purposes.* Dated June 13, 1862.

This consists of two or more plates or blades connected or joined together by a spring-bow, or jointed after the manner of a pair of scissors, one of the blades being larger than the other. The under blade fits the under side of the edge of the plate or dish, and the upper blade the upper side thereof. *Patent completed.*

1761. T. W. Fleming. *Improvements in preparing charges for firearms.* Dated June 13, 1862.

Here, when preparing charges for fowling pieces, the inventor encloses the slot in a cylindrical case of paper or other thin and easily broken material; this case he makes of a diameter to correspond with the bore of the gun. To the rear end of this case he attaches the propelling charge, consisting of a cylinder of compressed gunpowder, with a hole in one end of it, and he provides the rear end of the shot case with a projecting peg, which he makes, by preference, by screwing up the paper of which the shot case is made. This peg he introduces into the hole in the compressed cylinder of gunpowder, which thus becomes attached. In order to protect the compressed cylinder of powder from injury, from being carried in the pocket or otherwise, he uses a cap of pasteboard, which fits over the cylinder of powder, and on to the projectiles. In making ball cartridge he papers the projectile in the usual way, and screws up the paper so as to make a peg at the rear of the projectile, and this peg he makes to enter a hole in a charge of compressed gunpowder, as in the case of the sporting cartridge; and thus he attaches the propelling charge to the projectile, *Patent abandoned.*

1762. J. Bormingham. *Improvements in the construction of vessels of war, which improvements are also applicable to the construction of vessels for commercial and other purposes.* Dated June 13, 1862.

The principal novel features here consist in constructing such vessels of a flattened oval form in section, with the timbers running in a longitudinal direction from end to end, like the staves of a cask, the timbers being bound together by wrought-iron hoops, shrunk or driven in. The interior of the vessel is supported at intervals by transverse vertical divisions or bulk heads, which may also serve to divide the vessel into water-tight compartments. The timbers of the vessel all run off to a fine point at the bow, which is terminated by a solid iron beak or prow. For vessels for warlike purposes, the hoops enclosing the timbers touch each other, and form an armour or plating from end to end of the vessel. If a vessel all constructed of iron be preferred, longitudinal iron plates may be substituted. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Nov. 6, 1862.

3003. F. Goodyear, Old Change, St. Paul's. A machine for plaiting straw and such like material. (A communication.)

Dated Nov. 20, 1862.

3123. J. W. Hjerpe, W. Holmgren, and A. V. Sunstedt, Stockholm, merchants. An improved composition or preparation of materials applicable for igniting matches.

Dated Dec. 6, 1862.

3279. R. E. Donovan, Court Duffe, Dublin, gentleman. Improvements in the means and apparatus for the prevention of railway accidents.

Dated Dec. 11, 1862.

3318. I. Spight, Glandford Briggs, Lincoln, iron founder and agricultural machine maker. Improvements in horse hoes.

Dated Dec. 12, 1862.

3330. J. Gaskell, Blackburn, and H. Walmsley, Great Harwood, near Blackburn. Improvements in regulating the tension of yarn in the processes of warping, winding, sizing, weaving, and other similar purposes.

3332. A. Mills, Seaham Harbour, Durham, boot and shoe maker. Improvements in reefing and unreefing, furling and unfurling sails of ships and other vessels, and an improvement in the rotary yards and the journals in which the sockets or ends of the rotary yards work.

Dated Dec. 15, 1862.

3345. M. J. Roberts, Pendarren House, near Crickhowell, esquire. Improvements in means and apparatus for preparing and spinning wool, cotton, and other fibrous substances.

Dated Dec. 18, 1862.

3385. E. Habel and E. Suckow, Manchester, machinists. Certain improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous substances.

3389. J. Pernod, Avignon, France. A production derived from madders, called "purpurine."

3390. J. Savory, Bond-street. A new or improved apparatus for the inhalation of medicinal powders or vapours for the treatment of diseases of the throat and lungs. (A communication.)

3391. J. Longland, Landport, Hants. Improvements in street lamps.

3393. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved apparatus for transmitting power. (A communication.)

3395. I. Holden, Bradford, York, machine wool comber. Improvements in means or apparatus for washing wool and other fibres.

Dated Dec. 19, 1862.

3397. W. S. Longridge, Alderwasley Iron Works, Ambergate, Derby, engineer. Improvements in machinery for rolling tyres, hoops, and rings.

3398. E. B. Wilson, 5, Parliament-street, Westminster, civil engineer. Improvements in machinery or apparatus for forging and pressing metals and other substances.

3400. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved machinery for attaching metal eyelets to cloth and other materials. (A communication.)

Dated Dec. 20, 1862.

3402. J. B. Morrison, East Springfield, United States. Improvements in washing machines. (A communication.)

3404. A. T. Blakeley, 24, Montpelier-square. Improvements in breech-loading ordnance.

3405. J. Nettleton, 34, Sloane-square, Chelsea. Improvements in stoves.

3407. J. Cowpe, Mill End, near Newchurch, Lancaster, waste breaker. Improvements in machinery for tearing, breaking up, and reducing rags, ropes, waste fabrics, and other similar fibrous materials.

3408. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in the manufacture of automatic toy figures. (A communication.)

3409. J. Platt, Oldham, and W. Richardson, mechanical engineers. Improvements in scutchers or beaters of cotton, machinery also applicable to other machinery in which shafts are caused to revolve at high velocities.

Dated Dec. 22, 1862.

3412. J. McLean, Broxburn, Linlithgow, manufacturing chemist. Improved apparatus or arrangements for obtaining oil and other products from shale and the like bituminous minerals.

3413. W. Francis, Burslem, grocer. Improved apparatus for cutting soap.

3416. E. R. Dann, Nottingham, manufacturer. Improvements in goffering apparatus.

3417. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in stoves or apparatus for heating and drying. (A communication.)

3419. J. B. Dalhoff, Copenhagen, goldsmith. Improvements in cutting files, and in machinery to be employed for that purpose.

3420. C. Farrar, John-street, Horselydown, chemist. Improvements in machinery or apparatus to be employed in treating certain fibrous materials.

Dated Dec. 23, 1862.

3423. R. A. Brooman, 166, Fleet-street, patent agent. A new or improved colouring matter or dye. (A communication.)

3425. J. Patterson, Beverley, engineer. Improvements in machinery or apparatus for grinding, crushing, cutting, cleaning, and hulling or shelling various kinds of farm or vegetable produce, also applicable to the crushing or grinding of minerals and other substances.

3426. E. B. Wilson, Parliament-street, Westminster, engineer. Improvements in apparatus to be employed in the manufacture of malleable iron and steel.

3427. G. Haseltine, 12, Southampton-buildings, Chancery-lane. Improvements in the mode of, and apparatus for, converting petroleum or coal oil into gas for lighting and heating, the said improvements being especially applicable to lamps and stoves. (A communication.)

3429. S. Russell, 27, Shaftesbury-crescent, Pimlico. Improvements in stereoscopes.

Dated Dec. 24, 1862.

3430. T. C. Hinde, Cardiff, iron master. Improvements in furnaces or apparatus for generating carbonic oxide.

3432. G. H. Birkbeck, 34, Southampton-buildings, Chancery-lane, engineer. Improvements in instruments for surveying and levelling. (A communication.)

3434. F. N. Gisborne, 3, Adelaide-place, London-bredge, engineer and electrician. Improvements in the means for indicating the speed of ships at sea.

3440. H. Twelvetrees, Bromley, manufacturer. Improvements in washing machines.

3442. R. Lakin, Ardwick, Manchester, machinist, and J. Wain, Manchester, mechanic. Improvements in machines for spinning and for doubling cotton, and other fibrous materials.

3444. J. Taylor, Castle Iron Works, Stalybridge. Improvements in engines for carding cotton and other fibrous materials.

3446. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in apparatus for stamping or marking paper and other materials. (A communication.)

3450. C. J. Denton, New Broad-street, City, merchant. An improvement in the process of revivifying animal charcoal.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

2419. J. Watt and T. S. Haviside. Treating flax.

2433. A. Johnston. Pressing cotton.

2436. F. C. Bakewell. Fire places and stoves. (A communication).

2441. R. A. Brooman. Tools for boring. (A communication).

2449. R. P. Coles. Permanent way.

2507. J. and F. Walker. Combing, carding, or hackling fibrous substances.

2509. T. Molineux. Pianoforte actions.

2530. W. G. Rawbone. Gun barrels, and producing insciptions, ornaments, and devices, upon gun barrels, locks, plates, and other metallic parts of small arms.

2910. A. Krupp. Breech-loading ordnance and firearms.

3100. N. Thompson. Stopping bottles, jars, and other vessels.

3206. J. C. Robertson and W. C. White. Tap or cock.

3279. R. E. Donovan. Railway accidents.

3311. M. Osborne. Manufacture or cast-iron fenders.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Jan. 6th., 1863.

1735. W. Lennan.
1957. T. Edwards.
1961. J. H. Johnson.
1962. C. B. Gruner.
1969. H. Wethered.
1974. H. S. Pontifex.
1975. J. Rhodes.
1977. H. Eschwege.
1980. T. Green and R. Mathers.
1984. E. Jaudeau.
1986. J. Mander.
1991. J. Leeming.
1994. J. H. Johnson.
1997. J. Waithman.
1999. J. Orr.
2000. J. Miller.
2001. W. Bliss.
2012. D. Bateman.
2013. H. Barber.
2014. The Honourable W. E. Cochrane.
2016. G. Lowry.
2027. R. Ridley and J. G. Jones.
2035. T. G. Ghislin.
2054. J. R. Abbott.
2065. W. E. Newton.
2079. P. F. Cassegrain.
2091. A. C. Vautier.
2108. W. Clark.
2155. M. Henry.
2156. G. Nock.
2175. A. V. Newton.
2216. W. Clark.
2325. T. H Falkiner.
2404. W. Upfill, W. Morton, and W. Asbury.
2569. J. Bouvet.
2951. J. G. Marshall.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2993. W. E. Newton.
2997. H. Munster.
26. P. J. Worsley.
3000. J. Eason.
121. J. Burrows.
14. D. and S. Bateman.
25. J. Walls.
44. L. F. Perrier.
67. W. T. B. Allday.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

9. W. Bullough.
71. J. Ashworth, jun.
36. E. H. Bentall.
27. J. Fowler, jun.
44. H. Bessemer.
356. H. Bessemer.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 16, 1863.

ON AN INTERNATIONAL ASSIMILATION OF PATENT LAW.

A TRUE and new idea, whether embodied in a mechanical or chemical combination, whether developed in a product of art, or expressed in a literary work, is an international benefit. Such benefits are not limited to clime or race, but embrace all humanity, while supporting it in its moral, intellectual, and physical war for the necessities and luxuries of human life. The enunciator of a true and new idea being thus an international benefactor, how is it that such benefactors have never been rewarded by the comity of nations?

When either the patent for an invention, or the copyright of a book, or of a work of art is expired, the invention, in whatever form it may be, becomes international commercial property. Then, how is it that, with few exceptions, as in some cases of copyright and trade marks, a new idea does not receive international protection? In an article on Patent Law Reform, in our number for January 2nd, we placed in juxta-position certain clauses of the patent laws of the different countries—those clauses, namely, that bear upon the *novelty* of an invention. We believe that we were able to show, to some extent, how these different patent laws reciprocally hang together. We hope, in fact, that we made it plain to our readers that a patent, invalidated from want of novelty in any given country, was just as invalid in almost all the others. There being already more than 200,000 patents in existence, and also innumerable records and descriptions in home and foreign libraries, it may even be said that it is a mere question of time to upset eighty patents in any given hundred. If *absolute* novelty be required, scarcely any patent is tenable in any country. All these laws are at present built on a foundation of sand. We will now examine what international encouragement is given to invention as applied to manufacture, and will place in juxta-position the clauses of the different patent laws referring to imported inventions. We shall see how much these laws differ from each other. The position of the proprietor of an invention is the same in all countries. These laws cannot all be right, and some, therefore, must be unjust, both directly to the inventor, and indirectly to the country that might be enriched by the importation of an invention.

The present English law (14 & 15 Victoria, c. 83, clause 25), is as follows:—"Where, upon any application made after the passing of this act, letters patent are granted in the United Kingdom, for or in respect of any invention first invented in any foreign country, or by the subject of any foreign power or State, and a patent or like privilege for the monopoly or exclusive use or exercise of such invention, in any foreign country, is there obtained, before the grant of such letters patent in the United Kingdom, all rights and privileges under such letters patent shall (notwithstanding any term in such letters patent limited) cease and be void immediately upon the expiration or other determination of the term during which the patent or like privilege obtained in such foreign country shall continue in force, or where more than one such patent or like privilege is obtained abroad, immediately upon the expiration or determination of the term which shall first expire, or be determined of such several patents or like privileges: Provided always that no letters patent for, or in respect of, any invention for which any such patent or like privelege as aforesaid shall have been obtained in any foreign country, and which shall be granted in the said United Kingdom, after the expiration of the term for which such patent or privilege was granted or was in force, shall be of any validity." The English law does not fix any obligatory time for the working of a patent.

According to the present American law of May 4, 1861, in which are embodied the old laws of 1836, 1837, and 1839, "Even although the applicant has in good faith actually made an invention, a patent therefor will not be granted him if the whole, or any part of what he claims as new, had before been patented, *or described in any printed publication in this or any foreign country*, or even if it had before been invented or discovered in this country (Act of 1836, section 7), or if he has once abandoned his invention to the public; or if, with his consent and allowance, it has been for more than two years in public use on sale." (Act of 1836, section 6; Act of 1839, section 7.)

6. "The mere fact of prior invention or discovery abroad will not prevent the issue of the patent, *unless the invention has been there patented, or described in some printed publication.*" (Act of 1836, section 7; also Act of 1836, section 15.)

61. "If an alien neglects to put his invention in public sale within eighteen months after the patent is granted, and to continue it on sale to the public on reasonable terms, his patent will cease to protect him." (Act of 1836, section 15.)

59. "The taking out of a patent in a foreign country does *not* prejudice a patent previously obtained here; nor does it prevent obtaining a patent here subsequently.

"When the patent is granted here after being obtained abroad, it will extend only *seventeen* years from the date of the foreign patent."

According to the law of July 8, 1844, at present in force in France and Algeria, art. 29, "L'auteur d'une invention ou découverte déjà brevetée à l'étranger pourra obtenir un brevet en France; mais la durée de ce brevet ne pourra excéder celle des brevets antérieurement pris à l'étranger." This is similar to the British law. But according to art. 32, paragraph 2, "Le breveté qui n'aura pas mis en exploitation sa découverte ou invention en France, dans le delai de deux ans, à dater du jour de la signature du brevet, ou qui aura cessé de l'exploiter pendant deux années consécutives; à moins que dans l'un où l'autre cas, il ne justifie des causes de son inaction sera déchu de tous ses droits."

Whenever any great International Exhibition takes place, the question of protection to intellectual property is thrust forcibly forward from the very nature of things. Thus the present English law resulted partly from the Great Exhibition of 1851; and the proposed reform of the Patent Laws is in some measure consequent on the International Exhibition of 1862.

There is no patent law at present in Turkey, but we should not be surprised if a law should issue from the approaching International Exhibition in Constantinople. International Exhibitions are becoming international institutions, and an international convention as to patent rights is getting to be a universally felt necessity. The protection found necessary to offer to exhibited inventions, during the time of an International Exhibition, is of itself a rough international law. While upon the subject of a Turkish patent law, we will repeat a suggestive extract alluded to before the Patent Law Commission of 1852:—"In Thornton's 'History of Turkey,' he gives an account of a Turk who had invented a mode of making cast-iron which should be malleable, like wrought-iron. The secret died with the man, and, after his death, Englishmen spent some money and time in trying to buy his utensils, and taking such steps as occurred to them, to find out the secret, but they did not, which shows that some inventions are lost." This secret, as is well known, has been recovered. After the Great Exhibition in Paris, of 1855, the patent laws were also much discussed, and the result was a "Projet de loi sur les brevets d'invention," resulting from the deliberations of the "Conseil d'Etat" on the amendments proposed by the commission of the "Corps Legislatif," charged with the examination of the laws, 28th April, and 5th, 10th, and 11th May, 1859. As regards foreigners, this proposed law seems to be similar to the present one. We publish, in this number, a letter from a correspondent abroad, giving an account of the Austrian and Prussian patent laws.

The Austrian law of the 16th August, 1852, is framed in a just and equitable spirit towards foreigners. In paragraph 29 *b b*, an imported patent taken out in Austria is invalidated if it is proved that the patentee be not the original inventor or proprietor (cessionnair). According to paragraph 9 *c*, a patent imported from abroad into Austria expires with the mother patent. According to paragraph 29, 2 *a*, a patented invention must be put to work within a year from the date of the grant, and it also expires if it should remain for two years out of use. The Prussian law is simply a mockery for both Prussians and foreigners. A foreigner cannot legally obtain a patent at all. And yet many Prussian subjects—as, for instance, Mr. Krupp—possess very remunerative English patents. Prussia affords a very good lesson to opponents of patent rights. Having been for years substantially without a law, she is now introducing one. In England and in France, in which countries patent rights have existed for centuries, factious minorities are talking of their being abolished. As we said before, a patent law is now being discussed in Prussia, and it is probable that both France and Prussia are, to some extent, waiting for England to take the initiative in patent law reform.

Patent right is also just now the subject of some discussion in Belgium. The present Belgian patent law of 1854 is similar to the French law. A patent imported from abroad, expires when the original patent comes to an end. A patent must be worked (*exploité*) in Belgium within one year from the time it is put to use abroad. If it has ceased to be worked in Belgium for a year, it is to be considered as expired. The Dutch law is similar to the Belgian law, but two years are allowed to put the invention to work. There is a curious clause in art. 8 of the law of 1817. According to this clause, a Dutch patent is forfeited if the possessor should acquire an exclusive right to the same invention in any foreign country! According to articles 122 and 133 of the Russian laws of 1833 and 1840, if a would-be patentee be the veritable inventor and proprietor of the foreign patent, the duration of his Russian patent can be for 10 years, but in every case the term of the Russian patent must not exceed that of the original foreign patent. The patentee is allowed one quarter of the term of the patent, to put the same into operation (art. 142). According to the Swedish patent law of

1856, a patent, imported from abroad, cannot last longer than the original foreign patent. The patent must also be put to work within two years, a time which may be limited to one year by the Swedish examining commission, as also extended to four, if judged proper by the same commission. The Spanish law of the 27th March, 1826 (art. 3), says:—"Letters patent, for inventions imported from abroad (Patents of Importation), are only granted for five years, and available only for the working of the invention within the kingdom." Art. 21.—3, "If patentees have not put their inventions into practice themselves, or by others, within one year and one day; 4, If patentees give up their inventions by interrupting their works during one year and one day; 5, If the invention is published in a book, or by prints, models, plans, or descriptions, existing at the Royal Conservatory of Arts, or if it is worked in another country whilst it is represented by the patentee as new and original, the patent is invalidated."

The patent law of 1855 for the Italian kingdom does not give any right to the original foreign inventor before anybody who may choose to import and patent the invention in Italy. A patent from abroad lasts only as long as the original patent. A patent for five years must be worked within the year, and a patent for a longer period must be put to work within two years. According to art. 14, of the Portuguese law of 1837, a patent from abroad can only last five years in that country. It must be put into operation before the expiration of one-half of the term for which the patent has been granted.

Our article for Jan. 2nd must again be borne in mind. We showed therein that *absolute* novelty was everywhere required. We will, however, suppose that a man is in possession of that "rara avis in terris," an absolutely new invention, and that he wishes to secure the patent right in several civilized countries. To do this, a vast machinery must be set to work, and a proportionate amount of capital must be expended. We will again suppose that he is also provided with these requisites, and that he is an English patentee, with a patent just completed. This patent being completed, he finds that it is described in the MECHANICS' MAGAZINE, which is circulated in several foreign countries. He is thus debarred from several patents, and this is more especially the case, if we happen to have illustrated the new patent. Patentees intending to apply for foreign patents, often come to our office and request us not to illustrate their inventions, for this very reason. Of course we always accede to this request, as we should be very sorry wilfully to cause an injury.

The intending patentee finds out that it is scarcely possible to get a patent at all in Prussia. He finds that a patent is absolutely refused him in some of the British colonies—Canada, for instance. To obtain a patent in any foreign country, he must be quick; he must lose no time; as in several countries interlopers are allowed; and in no case, except America, will a foreign patent last longer than his British patent. In fact, an English inventor, intending to apply for foreign patents, must make arrangements for this purpose, at least two months previous to his British specification being filed.

After having obtained the foreign patent, in whatsoever country that may be, he discovers that he is everywhere, except in England and America, obliged to put his patent to work within a time, generally varying from a year to two years. The foreign Legislatures seem to be possessed with the idea that a man will go to the expense and trouble of a foreign patent for mere pleasure. A delay in working a patent will often take place from reasons quite independent of the will of the inventor. He may be poor, or his invention may bear upon manufactures already in the hands of large companies, who, refusing to take the invention up, have only to wait a year or two for it to fall into their laps. We have shown, in our preceding article on this subject, the difficulty of getting a new thing quickly and truly appreciated. This cause also comes into play.

Upon the question of importing a patent, we will cite a portion of the evidence of Mr. A. V. Newton, before the Parliamentary Patent Law Commission of 1851:—"That is a great difficulty; (in introducing new processes) it requires a party who has a great interest in it to break down the prejudices, and that is more or less necessary in the introduction of every invention: the more trifling an invention may appear to be, the less difficulty there is in introducing it; the more really valuable and important it is, the more necessary it is that there should be one party who shall have a large interest in it, and be able to give the whole of his time and attention to pursuing it. I know of many inventions which I consider, as far as I am able to judge, of immense value, which have yielded nothing, and, perhaps, will never remunerate their inventors, owing to their totally neglecting them, and I question very much if they will yield anything to the public either. There is another reason why I consider the clause, which affects the importation of inventions into this country, to be so objectionable, and that is, that English patents, when granted for native inventions, may be invalidated by evidence brought from a foreign country, that the invention was not new at the time of granting the patent. I think that that is the strongest objection, or, at least, as strong an objection to this clause as any former objection. No man, in this country, patenting an invention can be sure that he has a valid patent; it is an impossibility to satisfy himself upon that subject; and I think that, if for no other reason, that clause will be extremely injurious, because the patentee will then have all the world against him, as it were; whereas, now, he has only the parties engaged in the same trade as himself in his own country."

Of course, an international convention for the securing of intellectual property would be very difficult to bring about. By one of those coincidences that only occur during a lapse of centuries, the three nations in the van of civilization, namely, Great Britain, France, and Prussia, are now engaged in reforming their patent laws. Never will such an opportunity again occur of bringing about an international convention as to the laws of intellectual property. America has just lately reformed her patent laws. The old law embodied a rough attempt at reciprocity. International treaties already exist as to property in art designs, trade marks, and copyright.

The British laws bearing upon copyright and patent right merge in a remarkable way into each other. Copyright, however, is not the same as patent right, inasmuch as the author of a book cannot forbid the world to borrow his ideas, although he may forbid people to copy his ideas in the tangible way into which he has put them. We mean that he may prevent his book being published. We will, however, cite what *The Times* wrote in 1851 about copyright, as the meaning adopts itself very well to an international patent right. *The Times* is just now the chief opponent of patent right, so that it is not inappropriate to quote it against itself, although *The Times* may thus find an application of the well-known lines:—

> "That Eagle's fate and mine are one,
> Which, on the shaft that made him die,
> Espied a feather of his own,
> Wherewith he wont to soar so high."

"The most hopeless subject of negotiation with the Governments of other countries has long appeared to be an international copyright law. Intellectual "produce" has been the only description of goods excluded from equitable conditions of exchange. With regard to hogsheads of sugar, bags of coffee, and bales of cotton, there could exist no rational doubt that, sooner or later, the commercial transactions of the world would be placed on a rational footing. The advocates of exclusion and monopoly invariably fabricated an economic system in accordance with their own views, and endeavoured to invest it with the most fascinating attributes of philosophy and justice. There was error in their calculations; but it was error under the colour of reason, and wrong under the semblance of right.

"The property in intellectual works has been regarded from a different point of view. The various Governments of Europe, and of the United States of America, have, from time immemorial, declared that a work of literature or art, the property of a single individual in a single nation, was a fair mark for piracy and theft. Genius has been outlawed. The property it should have owned, whether in its most splendid or most trivial productions, has, by the comity of nations, been treated in the same way as the goods of a convicted felon.

"All this has been done in the broad light of day, under the sanction of the most distinguished statesmen of the most civilized nations of the world. Ignorance must not be pleaded in bar of the indignation which such a policy is calculated to inspire in any mind not destitute of the first impressions of right and justice."

There are already international conventions for protecting intellectual property in literary and art produce. Now a patent often protects a product that embodies a triad of scientific, artistic, and practical merits. A true engineer has the brain of a scientific man, the heart of an artist, in inventing and putting his invention into an elegant shape, and lastly he stands on the strong legs, and works with the skilled hand, of the artizan. Every sound art stands on a mechanical trade for its basis.

Although it is the case, that the merit and difficulty in inventing are very great, nevertheless it is a great mistake in legislation to give a patent for any scientific combination as a reward of merit only. Every man in the possession of a sound patent is a kind of trade missionary, preaching and exhorting people to reform expensive and laborious ways of manufacturing.

We know, from very competent authority, that, during the last harvest of 1862, the scarcity of labour in Spain was so great, that the harvesters were paid extremely high wages—wages that would be enormous even in England. In fact, we should be afraid to state what these men got. In some districts much grain was spoilt. Nothing of this could have happened if a good reaping-machine had been already introduced into the country.

We believe that Mr. M'Cormick is now engaged in introducing his well-known reaper into Spain.

It is remarkable that the nations the most advanced in industry, such as Great Britain, America, and France, are at the same time the most liberal in their patent law legislation. The nations that are most in want of progress and of help, such as Turkey, and to some extent also Germany, are the most retrograde and narrow-minded in encouraging patent rights.

What we propose as the basis of future cosmopolite legislation would be that "*all inventions and discoveries should be accepted as new in any given country which had not been worked in that country for the last twenty years.*" A further clause, giving a preference to the original inventor or discoverer, could easily be inserted.

Such an international convention, or assimilation of patent right, throughout the different nations, would act as a bond between the most active and powerful spirits of the age. This would, indeed, be FREE TRADE in inventions. We will conclude this notice on an extensive subject, in the words of that Prince of Science and of men, who has just passed from among us. They were spoken by Prince Albert, at the famous Exhibition Mansion House banquet of 1850:—

"Nobody who has paid any attention to the peculiar features of our present era, will doubt for a moment that we are living at a period of most wonderful transition, which tends rapidly to accomplish that great end to which, indeed, all history points—*the realization of the unity of mankind.* Not a unity which breaks down the limits, and levels the peculiar characteristics of the different nations of the earth, but rather a unity, the result and product of those very national varieties and antagonistic qualities.

H.

SUCKING AND BLOWING THE MAIL.

JUST two hundred and eight years have elapsed since the then Burgomaster of Magdeburgh, Otto von Guericke, invented the air-pump, and astonished the Emperor of Germany at Regensburgh, by exhibiting the apparatus in action. By means of his contrivance he exhausted a tube wherein a piston was fitted and made to slide easily, and thus raised a heavy weight to a considerable height. Since the time of the ingenious and scientific Burgomaster—who, it is some satisfaction to say, had previously been a student at Oxford University—many efforts have been made to employ atmospheric pressure in the performance of mechanical, and industrial operations. These efforts have, for the most part, proved failures, commercially or practically, and we really have not succeeded to any extent as yet, in pressing the atmosphere into active service. Everybody remembers the various railway schemes on the atmospheric principle which, from time to time, have occupied the attention of our cleverest mechanics, and all know that they have been abandoned. Mr. Brunel tried the system in South Devon until the patience of the shareholders with whom he had to deal was exhausted more completely than the propelling tubes of the railway ever was by the application of his gigantic pumps, and then the whole of his costly apparatus was sold as old iron. The Kingstown-Dalkey atmospheric line maintained its ground longer than any other, but it at last yielded to the Locomotive, and has ceased to exist. These are certainly far from being encouraging facts, but they assuredly will not deter other inventors—worthy disciples of Otto von Guericke—from perseverance in the same direction. For their comfort, it may be mentioned, that in one remarkable instance, at least, atmospheric pressure has been made subservient to mechanical art, and is employed efficiently and economically. The Coinage of the British Empire is stamped entirely by its force. We have not space nor time at present to enter into a description of the beautiful arrangement of air-pumps, vacuum chambers, levers, springs, and valves, by means of which impressions are given at the Mint, with rapidity and precision, to the coins which issue from that establishment. It must suffice to say that the air we breathe literally coins the money we use, and that therefore there is yet hope for atmospheric engineers. It is now proposed to make the atmosphere our General Postman, as well as our Chief Coiner, and we cannot see any practical obstacle to its becoming so. The only doubtful point—and it is one which actual experiment can alone solve—is the commercial one. That atmospheric pressure may be made to transfer letters and parcels by wholesale from the Land's End to John o' Groats, is a certainty. That its employment, in lieu of other modes of transit, will effect advantages in a pecuniary sense, is another question. The Pneumatic Despatch Company, which has now been in existence some two years, answers the important query affirmatively; and on a comparatively small scale they are essaying to demonstrate the truth of their views.

On a piece of waste ground, the property of the North-Western Railway Company, and to the right of the carriage entrance of the Euston station, the would-be atmospheric letter carriers have erected their first pneumatic apparatus. An engine-house—for steam is the prime mover after all—has been built on the spot named, and this shelters an engine of some 20-horse power, with boiler and appurtenances, together with a gigantic disc of some 21 ft. in diameter, and which is hung upon the horizontal crank shaft of the engine. This disc, which is hollow and of wrought iron, is virtually an air pump, and it is divided into a number of small chambers. When the disc is in motion, these, like so many mechanical fans, gather air at the centre and emit it at the circumference. It is intended that this centrifugal disc shall make 300 revolutions per minute; and as its centre is to be in direct communication with the interior of the conveyance, or vacuum tube, it is clear that this latter may be exhausted to an extent governed by the speed of the disc, and the weight on the relief or regulating valve opening into the tube. The tube itself consists of a series of cast-iron socket-ended pipes in 9 ft. lengths, jointed together with molten lead, and resembling in sectional forms the old-fashioned waggon-ended boiler of Watt. The height of the tubes, from floor to roof, so to speak, is 2 ft. 8 in., and their width also is 2 ft. 8 in. The upper part or roof is semicircular, whilst the lower part is nearly flat. Along the two sides of the base of the tube run narrow longitudinal flat surfaces formed in the castings, and these constitute the tramway upon which the carriages are to travel.

The carriages themselves are made of stout boiler-plate. They are about 4 ft. 6 in. in length, have a deep hold for the reception of their cargo of letters, parcels, merchandize, and are each mounted on four small wheels of cast-iron. The carriages are of the precise form of the tube, and though they by no means fit its interior closely, they yet may be said to represent pistons. About a quarter of a mile of this tubing has been laid down, and it connects the engine-house at Euston with the North-Western District Post-Office in Eversholt-street, Camden-town. At each end of the conveyance pipe, as we may henceforth term it, an iron cover of sufficient area to seal its mouth is hinged. These covers have been faced in the lathe, and, when lying on their diagonal seats, form air-tight joints. Such are the main features of the apparatus of the Pneumatic Despatch Company, as at present established, and almost perfected for trial at the place indicated.

It will now be understood, if our explanation is sufficiently lucid and minute to make it so, that it is quite possible to pump the air from the conveyance pipe. Well, then, supposing it be desired to transfer a loaded carriage from the Post-office to the railway station, it will be simply necessary to push it (the carriage) forward on rails corresponding with those in the inside of the tube, close the engine house end, start the disc, remove the air from the front of the carriage, and allow the external atmosphere to push it forward to its destination. The speed at which it will travel will depend on the extent of the vacuum, which is again determined as we have described. This operation may be justly termed "sucking" the mail.

It may seem strange to some that the carriages do not fit the pipe, and the possibility of forming a vacuum at all, under such circumstances, might well be questioned; but the answer is, that the area of the end of the carriage is great, the vacuum low, and the air-space or windage, consequently, not sufficiently large to allow of the "killing" of the vacuum by the rush of air through it. The atmospheric pressure will not, as a rule, exceed 5 lbs. on the square inch.

At the head of this paper we speak of "blowing" the mail, as well as sucking it. This operation the Pneumatic Despatch Company propose to do by inverting the action of the disc, and causing it thus to force or blow air *into* the conveyance pipe, instead of pumping it *out*. It is evident that it is as necessary to be able to send parcels, &c., from Euston to Eversholt-street, as to despatch them from Eversholt-street to Euston. This can only be done by erecting an engine and accessories at the Post-office, as well as at the station, or by *blowing* the carriages one way, and *sucking* them the other. We are of opinion that in the *blowing* part of the process failure awaits the company's exertions. The power required to displace the air in front of the carriages, and move them at any speed, will be very great, and the cost of doing it excessive—at least, we think so. It would be much more advantageous to continue the conveyance pipe to a greater distance—say, some four or five miles, even to the General Post-office, and then erect "sucking" apparatus at both ends. No doubt the transport of the Camden-town machinery from Battersea-fields, and its re-erection, have been attended with considerable expense, as we know they have with much difficulty. The laying of a large tube at a depth of four or five feet below the surface of a street—that street being already occupied by a net work of gas and water mains, with their connections—is in itself no trifling task. It is to be trusted that final success will repay the shareholders for the labour and the money which have been expended. It may be stated, finally, that the nonfitting of the carriages enables them to pass freely over steep gradients and sharp curves, which is fortunate, for these will have frequently to be encountered in laying conveyance pipes through the great thoroughfares of London. Messrs. Rimmell and Clarke are the engineers, and James Watt and Co. constructed the engine and machinery.—*Building News.*

Dr. Hutton estimated that the first force of gunpowder is equal to 30,000 lbs. on the square inch, and Robins computed that the velocity of expansion is about 7,000 ft. per second.

LONDON FIRES.

Captain Shaw, the successor to poor Mr. Braidwood, as Superintendent of the London Fire Brigade establishment, has just issued his annual report to the General Committee of the twenty-eight Fire Insurance Offices in union for the Suppression of Fires in the Metropolis. The document is very important and instructive; would that we could say, also, with some of our contemporaries, that we think it "satisfactory." It is, on the contrary, difficult for us to find anything at all in Captain Shaw's report which would justify such an expression. It seems that during the year 1861 no less than 1,303 fires, some of which were of an extremely destructive character, occurred in the Metropolitan Districts. This gives an average of rather more than three fires per night, twenty-five per week, or one hundred and eight per month. Surely this is not "satisfactory!" If we institute a comparison between the number of fires in some previous year, say, 1833, for example, we shall find that even taking altered circumstances into account, the results will be very *un*satisfactory. In the year last named, the number of fires in the same districts, as reported by the then superintendent of the brigade, was just four hundred and fifty-eight. This gives an average of little more than one fire per night, nine per week, or thirty-eight per month.

Is not this simple fact an overwhelming proof of the totally inadequate means at our disposal at present for the suppression of fires? It will, perhaps, be said that the house, area, and the population of the Metropolitan Districts have grown very considerably during the intervening thirty years, and that, therefore, a larger number of fires may now be reasonably expected to take place. This may appear, at the first blush, to be a tenable, if not a feasible, explanation of the sad increase in the number of fires recorded in the year which has just passed. A cursory examination of the argument will probably demonstrate its groundlessness. It is perfectly true that the progress of building in and near London since 1833 has been very extensive, whilst the last Census demonstrates the existence of a vastly increased population. This growth, however, has been gradual, and patent to all. Ought not, then, the numerical strength of the corps organised to combat with the "destructive element," and the means and appliances with which they are armed, to have grown in a proportionate ratio?

Since the year 1833 enormous strides have been made in mechanical knowledge. Steam power has become almost universal in its application, while science has opened up its "ample page" and enabled us to imbibe lessons which have been turned to much practical account. Should not these advantages have placed us in a far more favourable condition for overcoming fires? If the metropolitan districts are more completely built upon, and more densely peopled, ought not corresponding precautions to have been taken against the increased risk? At least, we ought not to be in a worse position in those respects than we were thirty years since. The per centage of fires, to houses and population in 1861, is much higher than it was in 1833, and this with all our boasted improvements in the construction of dwellings and warehouses, increased mechanical skill, and extended knowledge of the laws of Nature. Surely, then, there must be a fault somewhere. There must be a reason or reasons for the deplorable and alarming state of insecurity in which the inhabitants of London now find themselves in regard to fires.

The Seasons seem, according to Captain Shaw's report, to have little to do with the increase or diminution of the number of fires in London. It was once the popular belief that winter was most fruitful of those disasters. The tabulated monthly summary of fires for last year dissipates that delusion. Destructive fires are now in season all the year round, and in 1861 the greatest number, 136, took place in the month of August, whilst the minimum, 86, was attained in October.

Without going at present more minutely into an analyzation of the document in question, it must be permitted us to say that it constitutes, as a whole, one of the most convincing arguments that could be adduced in favour of a total reformation of the London Fire Brigade, and a transference of its management to other hands.

It is true that the Superintendent points exultingly to some changes which have been effected since his Accession to power, and those changes have certainly tended in the right direction. They are, nevertheless, but inklings and foreshadowings of the great and sweeping changes which are to come.

We are told that "in the steam department a considerable increase has been made, and that, at least, one land steam-engine is available at almost every fire. Telegraphic communication has been established between the Central Station and those occupied by the firemen of the districts." This arrangement, we remember, was strongly urged, in June, 1861, in the Mechanics' Magazine, by Mr. Newton, of the Mint; and we are glad to see that it has been so promptly carried out. Captain Shaw testifies to its value in the following words:—"It is impossible to over-estimate the advantage of the telegraphic mode of communication, which, though it has only been a few weeks in operation, has already been the means of saving a large amount of property, and, moreover, assists me very materially in carrying on the daily and hourly duties of an establishment which is, necessarily broken up into a number of fragments and distributed over a large area." The numerical strength of the brigade has been increased by the addition to its ranks of 14 men, and it now numbers, in all, 130.

In conclusion, we can only trust that during the coming session of Parliament the recommendations of the Select Committee of the House of Commons, which reported last year in favour of a great extension of the Fire Brigade, and the placing it under the control of the Metropolitan police authorities, will be adopted. It has been a serviceable institution in its day, and may yet form the nucleus of a much-extended and more perfect one—one organised, controlled, and in all respects appointed so as to meet the wants, and satisfy the just expectations, of the residents of the Metropolis of the World.

Proceedings of Societies.

◆

ROYAL SCOTTISH SOCIETY OF ARTS.

The third meeting for the session of the members of the Royal Scottish Society of Arts was held on Monday night, at Edinburgh. Dr. Stevenson Macadam, president of the society, in the chair.

Mr. **George Russell**, engineer, St. Vincent-street, Glasgow, gave a description of an improved riveted joint applicable to iron ship-building, girders, bridges, &c. The improvement proposed by Mr. Russell was to arrange the rivets in the form of an equilateral triangle form each side of the butt, making the covering plates of the form of a parallelogram made up in form of two equilateral triangles, having a common base. The paper was remitted to a committee.

Mr. **J. M. Balfour**, C.E., gave a description of a simple improvement on reflectors for light-houses. The improvement consisted in the use of a plain horizontal reflector, in combination with another of a parabolic section. The reflector was fitted with an auxiliary tube, and from experiments which he had made, he had observed a considerable increase in brightness and in the apparent size of the light. This paper was also remitted to a committee.

The report on Mr. Warner's "Stereometric Tablet," for facilitating the computation of the solid contents of railroad excavations and embankments, was to the effect that the committee considered it an ingenious and scientific attempt to lessen the heavy labour of railway computation.

The committee which was appointed to consider Mr. D. Campbell's communications on sulphuret of iron, as a cement for fixing iron railings, &c., reported that, to the best of their knowledge, Mr. Campbell's use of sulphuret of iron for this purpose was quite new, and, at the same time, a great improvement on all former cements used for the same purpose. The committee recommended Mr. Campbell's communication to the favourable consideration of the Prize Committee.

The following gentlemen were admitted members of the Society:—Messrs. David Craig, papermaker, Portobello; James Andrews, C.E., George-street; R. W. Thomson, Moray-place; Peter M'Lagan, of Pumpherston; J. A. Mackay, of Blackcastle; and George Blanshard, wholesale druggist, Carlton-terrace.

ROYAL GEOGRAPHICAL SOCIETY.

The Atlantic Telegraph.

An interesting meeting of this society was held on Monday evening last; Sir Roderick I. Murchison, president, in the chair.

Dr. **G. C. Wallich** read a paper on the question of a Survey of the Physical Condition of the Atlantic, preliminary to the laying down of another electric cable connecting Europe with North America. Dr. Wallich began by pointing out that both the amount and kind of information we now possessed regarding the deep-sea bed of the Atlantic were altogether inadequate to meet the requirements of oceanic telegraphy. Referring, in proof of this, to the line of soundings taken by Captain Dayman, in 1857, on board her Majesty's ship "Cyclops," he observed that these, though as perfect as circumstances then allowed, furnished data necessarily incomplete; inasmuch as only 41 soundings were taken at depths exceeding 250 fathoms, across an area of 1,300 miles of ocean, leaving a mean interval of 32 miles between each two soundings. Having assigned his reasons for disbelieving that the entire central basin of the Atlantic is, as many have supposed, a vast plateau, unbroken by alternations of level as great as those existing on land, he observed that in the intervals between the previous measurements of the depth of the ocean-bed some of the largest mountain ranges might very well be included—a matter obviously most important, as bearing upon the safe laying of a telegraphic cable. True, no such submarine slopes had hitherto been detected in the mid-Atlantic, but the *data* on which it was assumed that they did not exist there were, he maintained, purely arbitrary. A sounding of 100 fathoms had been taken by Lieutenant Sainthill, R.N., within about 32 miles of one of 3,000 fathoms, taken by Captain Dayman. Dr. Wallich then enumerated the various kinds of observations that he thought essential to a trustworthy telegraphic survey, among which was a method of probing the deposits of the sea-bed, with a view to determine their geological character. He exhibited an ingenious instrument, designed by him to effect this object, besides other new apparatus for raising specimens of water from any desired depth, and for gauging the pressure at all depths. Passing to the means requisite for carrying out his survey, Dr. Wallich recommended that the Government should equip two steam-ships for the work; the great novelty of his plan consisting in the two vessels sailing in parallel courses, removed only 2 miles from each other, and the soundings being taken alternately on each line of the longitudinal belt thus defined. While, therefore, there would be an interval of 5 miles at the utmost between any two soundings on the same line (that was, taken by the same ship), there would be an interval of only 2½ miles between those on alternate lines. Having indicated how a minuter inspection of doubtful or dangerous areas might easily be effected, he suggested that Captain Dayman's line of soundings should form, as it were, the base of operations, and be taken as the centre of the 2-mile longitudinal belt which he proposed to have surveyed. The entire work might, he thought, be finished in five or six months. Summing up the advantages of his plan, he remarked that it would furnish no less than 640 reliable observations, extending across the entire deep water of the Atlantic, and affording a basis upon which its whole sea-bed might ultimately be mapped out. In conclusion, he said the task was unquestionably arduous. Its execution might prove costly and tedious. But there it was, staring us in the face—a task which we must either manfully grapple with and master, or leave unfulfilled to our successors the accomplishment of the grandest international project that human sagacity had heretofore suggested. The paper was listened to with marked interest, and repeatedly applauded.

The **President** reminded the meeting that Dr. Wallich accompanied Sir Leopold M'Clintock in his North Atlantic explorations, and had since published a valuable work on the natural history part of the exploration. In his elaborate paper he had thrown some light on the nature of the animals existing at the bottom of the sea, and on the varieties of soils, and even subsoils, that were to be found there; for with the ingenious apparatus which he had explained, he was able not only to tap the soft strata, but even to bore into the solid rock. The survey which he proposed was a preliminary one, and essential before any attempts were made to lay down a telegraph cable across the Atlantic. At all events, whether any adventurous persons chose to undertake that preliminary survey, it became us, as a great maritime nation, to ascertain as accurately as possible the condition of the bed of the ocean between England and America, with the view to telegraphic communication being established.

Sir Edward Belcher, R.N., as the senior surveying officer present, thought it is duty to answer some portion of the paper. Such a project as Dr. Wallich proposed would answer very well across the Irish Channel; but from his experience in searching for shoals even within 100 yards of his own ship, for six weeks and fourteen hours a day, he knew the difficulty of finding a rock, not much larger even than the President's chair. Any such survey, therefore, would cost an immense sum of money, would incur more labour than the men would like, and would be attended with innumerable difficulties, which would render the carrying out of such a project absolutely impossible. For a telegraph cable, it was not the deepest water that was wanted, but a line of bottom which would give mud and avoid mountains; nor did he think many scientific men were of opinion that it was desirable to carry a cable straight across the Atlantic. If they carried the line from the Hebrides or the Orkneys to the Faroe Islands, and so on in that direction, a simple mode of being sure of what they were about would be secured; they would know, with such small lines, positively what bottom the cable would lie upon. To carry a cable from point to point might be done at a small expense, and in that way they could feel their way across the ocean. With reference to the apparatus explained by Dr. Wallich for sounding the bottom of the ocean, he might state that in the soundings which he carried on, in 1835 and 1836, a very accurate instrument was used, not only for sounding, but also for determining the temperature at different depths, and bringing up the water. He explained the construction of that instrument, and stated that it was in use for a period of twelve years, without the slightest derangement of even the delicate thermometers that were attached to it. He thought, before the Government was moved to incur the cost and labour of carrying a line of soundings across the Atlantic, the opinions of scientific men should be taken as to whether it would not be better to have several stations for the cable, instead of one long line.

Admiral Elliot doubted whether the survey proposed by Dr. Wallich would render them any wiser with regard to the laying down of the Atlantic cable, because it was impossible to thread their way across the ocean in the way Dr. Wallich supposed, and avoid mountains and hollows that might be found to exist. Nor did he think such a method of sounding practicable: and to keep the laying of the cable in abeyance till it was accomplished would be inexpedient.

Professor Tyndall said, as far as the physical objects indicated in the paper were concerned, he did not think they were of sufficient importance to justify any great outlay. He confessed he had arrived at a conclusion somewhat in accordance with that of Sir Edward Belcher and Admiral Elliot. Even if Dr. Wallich's survey were carried out, it could not, with five mile intervals, give an accurate view of the bed of the ocean; knowing what we did of the variations that occur within five miles on the earth's surface, how easily such a projection as that of the Matterhorn might be missed.

Captain Selwyn, R.N., said the diagrams of soundings taken by Captain Dayman, R.N., not having been thoroughly understood, had given rise to the supposition that there was a precipice off the shores of Iceland. He had been engaged, in company with an officer of the Admiralty, to measure the exact distance between the soundings and the depths, and they ascertained that the fall on the bank in question was not greater than that of Holborn-hill. No one would imagine that a cable would be injured by such a descent as that, nor that there were precipices so abrupt as to hold the cable on the stretch between them. Again, it was utterly impossible to find out whether abrasion would be caused, and it would be combatting with theoretical difficulties to delay laying the cable until the exact character of the bed of the ocean between England and America had been thoroughly determined. With respect to the best route, he could suggest a shorter one by 300 miles, by taking the cable to the Flemish banks, 300 miles this side of Newfoundland, where the depth varied from 30 to 200 fathoms. He also thought that the proper method of survey would be to adopt the system of triangulation.

Mr. Webster argued that the laying of the cable would of itself enable us to obtain a knowledge of the bed of the ocean much more effectually than by any survey.

Dr. Wallich briefly replied, defending his plan from the objections that had been urged against it, and adducing further reasons against the adoption of the counter telegraph-route suggested by Sir E. Belcher.

The meeting was then adjourned to Monday, the 26th January.

SCOTTISH SHIPBUILDERS' ASSOCIATION.

On Monday week this association held their usual monthly meeting in the Queen's Rooms; J. G. Lawrie, Esq., vice-president, in the chair.

A letter was read from the Deputy-Chairman of Lloyd's Committee, requesting the association, as a body, to favour the committee with their views on "Lloyd's Rules for the Construction of Iron Ships," preparatory to an amendment which is now considered necessary, from the increased experience of shipbuilders and the committee in the construction of iron vessels. The committee has, already, requested the shipbuilders individually all over the kingdom to submit any suggestions that they might consider advisable; but, for the purpose of meeting the request of the committee to the association in a friendly spirit, and furthering the object contemplated, the association appointed a committee to draw up and submit such suggestions as the association may deem most advisable for the improvement of the construction of iron vessels.

Mr. R. Duncan, of Renfrew, then read a paper explanatory of an improved slip dock, and also of a self-acting tide-gauge, by which the exact rise and fall of tide for any height, from 1 foot to 100 ft., could be registered with the greatest precision for any length of time. Mr. Duncan's models received honourable mention from the jurors of the International Exhibition; and having in the handsomest manner presented them to the association, he kindly consented, at the request of the council, to favour the association with a description of the principles and improvements embodied in them.

Dr. James Gray next exhibited and described a plan for cleaning the bottoms of iron vessels, and preventing fouling. It consists of an ingenious application of pulleys, lines, and brushes, for sweeping the bottom from the water edge to the keel, whether the vessel were at rest or at sea.

Considerable discussion followed the reading of both papers; and the thanks of the association were awarded to Mr. Duncan and Dr. Gray for the able and earnest manner in which they had studied and treated their respective subjects and laid them before the association.

ENGINE ROOM TELEGRAPHS.

We informed our readers, some two or three years ago, that an order had been issued from the Admiralty to the effect that all vessels of war, except gun-boats, were to be fitted with engine-room telegraphs. We also remember drawing attention to a series of experiments in 1858 and 1859, which had been instituted by the late surveyor of the navy and the Admiralty, and which extended over a long period, no expense having been spared in the matter. These experiments were made under the direction of one of their Lordships' most experienced officers, Capt. Halsted, and other officers of the steam reserve at Sheerness, in order to procure the most efficient and reliable means of communicating the orders of the captain from the bridge, &c., to the engine-room. Makers of such instruments were called upon to fit each one his own apparatus to certain ships, to be tested according to a series of moves and workings as to the relative mechanical efficiency and workmanship. It may not be out of place to mention the names of the several competitors (see *Mechanics' Magazine* of May 27, 1859). The greatest number of perfect marks and working was attained by Mr. T. Suffields, of Bermondsey-wall, who obtained 600 marks. Mr. A. P. Hows, and Mr. Hornseys came next; and, lastly, Messrs. Allen and Crispens obtained about 150 marks. Of those that were indifferent or bad, Suffields alone registered none.

The late surveyor, coinciding with the expressed opinions and reports of the officers of Sheerness yard, issued orders for a number of the most successful telegraphs to be fitted to line-of-battle ships. Now, however, strange to relate, after a lapse of three years, in order, as it is termed, to "economise," and "other reasons, to be afterwards named," their lordships seem to have adopted several of the most unsuccessful instruments. These measures have, therefore, been naturally causing some comment, not only only from the officers concerned, but from practical naval engineers.

Evidence can be produced of the failure of an instrument constructed on the principle of common cranks and wires, &c., by which means the Admiralty are now endeavouring to communicate those important orders that are interchanged between the captain to the engineer. Every householder knows the liability of his bells, cranks, and wires to failure. Then what must we expect when such apparatus are fitted to line-of-battle ships, &c., labouring and working at sea? No wonder the officers express surprise at being compelled to rely upon what they know to be so liable to error. One of these instruments, at a late trial, completely failed in the presence of a high official at the Admiralty, which failure was, however, hushed up.

The Lords of the Admiralty, says the *Times* of Tuesday last, "have directed plans to be prepared by which boats' falls may be led in board and secured to bollards, so as to ensure a rapid and uniform lowering (of boats) when required." So much for the encouragement of mechanical science at Whitehall! While the use of blocks and falls have long since been discarded at every dock, wharf, or building-yard in the county for lowering goods or merchandize, from the constant liability to accident arising from the large quantity of rope or chain they employ, the Lords of the Admiralty are now setting their officers to work to improve these primitive contrivances, which the rest of the world has long since superseded by others altogether superior in mechanical action. We need no stronger official admission than this of the inability of the detaching hooks, in conjunction with the falls, (lately ordered to be fitted exclusively in the ships of the royal navy, as commissioned), to accomplish the ends it has been pretended they effect, viz., a safe and rapid lowering of the boats. The principle commonly employed for lowering all other heavy weights must hold good for lowering boats, and the one single part of rope or chain must eventually supersede the quadruple combination of former days, that their lordships are now uselessly setting their officers to puzzle their brains to make the best of, and which, if accomplished, will only exhibit the naval world behind all others in its application of mechanical science, to overcome simple mechanical difficulties. "How not to do it" never had a better illustration than the tortuous process the Admiralty has employed of late years for finding out the correct principle by which to lower ships' boats safely. When more victims have been sacrificed, "their Honours" may at last discard the blocks and falls, and poor Jack have the safer and readier system of lowering his boat, with its living freight of human beings, that every builder or wharfinger has long since used for the greater security of his logs of timber or his flour barrels.

On Thursday fortnight a mixed train started on the Great Eastern Railway from Newmarket for Cambridge. It had not proceeded far on its journey when it was ascertained that one of the goods' trucks was on fire. The guard *being unable to communicate* with the driver, three miles were traversed before the train stopped. The guard then contrived to uncouple the burning truck, and the engine dragged it swiftly away to the next station, but before it arrived there it was nearly consumed. Unfortunately, a passenger carriage had been attached to the truck, and the passengers were for some time in an alarming position.

GRIFFITHS' IMPROVED PROPELLER.

Mr. Robert Griffiths, of the Mornington-road, Regent's-park, has just patented an improvement in screw propellers for ships, which consist, first, in constructing the propellers with the blades and centre boss of similar form and construction (or the blades may be cast on the boss) to those described in a former patent, dated 20th February, 1858, but having four blades (or two sets of blades), which are to be fixed either to the same boss, or to separate bosses on to the screw shaft, and so fixed that one set (or pair of blades) is placed before the other set, the first set or pair of blades next the shaft to be of larger diameter than the after set, so as to get a greater hold on the water for propelling the ship.

Fig. 1 of the accompanying engravings shows a screw propeller arranged as above described, the two pairs of blades *a* and *b* being affixed to separate bosses, the boss *a* of the pair nearest the stern of the vessel being fixed upon the screw shaft, whilst the boss *b* of the hindermost pair of blades is loose thereon, and is coupled with the boss *a* by projections, which enter grooves or recesses formed around the boss *a*.

The second part of this invention relates to side wheel propellers, which is constructed of discs of suitable diameter, having the centre parts constructed with arms and centres similar to those generally used for paddle wheels, but having the outside rims of such discs corrugated or in a zig-zag form, instead of being flat, in order to offer sufficient resistance when driven through the water to propel the vessel. Either one or a series of these discs or wheels can be used on each side of the vessel as may be required to propel the ship, or the outside rims may be made flat, and the inside rims only be made corrugated or in zig-zag form.

Figs. 2 and 3 show a side view and plan of a side wheel propeller so constructed. *a*, *a*, are two corrugated metal rims combined and rivetted together, having narrow spaces between them, and supported between the two flat outer rims *b b*, attached by arms to the centre boss fixed on the main shaft or axis *c*.

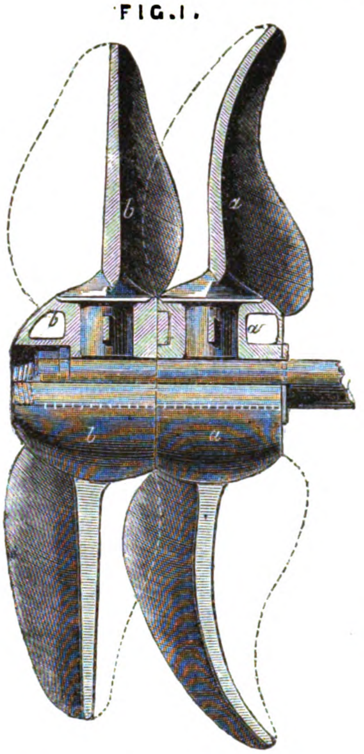

FIG. 2.

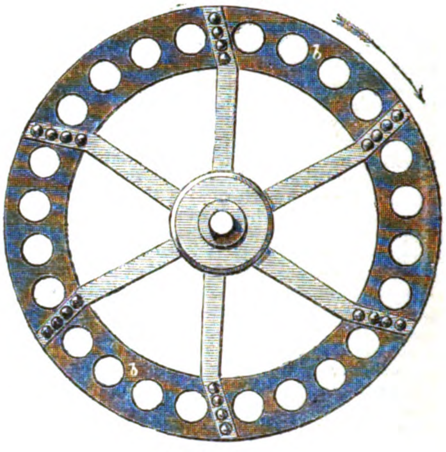

FIG. 3.

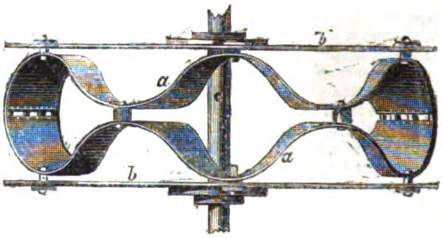

HORNSBY AND SONS' NEW TURNIP CUTTER.

Provisionally protected December 4th, 1862.

We gave last week some illustrations and a description of the root pulper, first exhibited by the above well-known Grantham firm, at the last Smithfield Club Cattle Show. They also exhibited a turnip cutter at the same show.

The new turnip cutter of Messrs. Hornsby and Son, shown in the engravings, is composed of a revolving disc wheel, having angle knives (commonly known as Gardner's) fixed on a bar, which is so curved, that the knives in cutting the roots tend to draw them to the centre of the disc, and as each knife strikes the roots in regular succession, the wedging between the knives (where they are placed in a V form) is thus obviated.

The disadvantage of the cut pieces having to pass through a cylinder before falling, and thus becoming discoloured, is avoided by the disc wheel, which is of sufficient size and weight to render a fly wheel unnecessary. The peculiar form of the hopper conducts the roots steadily to the cutting surface, and the grating allows the dirt or small stones to pass through before they come in contact with the knives.

By means of a patented flange on the disc, combined with a vertical board placed underneath the hopper, at such a distance that the knives will just pass clear, the last piece will be returned to the feeding hopper, so as to insure its being properly cut.

The machine is mounted on a strong wood frame, with improved iron hopper, and the working is equalized by the improved arrangement of the knives or cutting wheel, while, at the same time, it effectually cuts the last piece.

The knives are fastened to a bar which is bolted to the disc, so that they can be taken out either singly or collectively for sharpening. The usual knives for cutting pieces for sheep can be removed at pleasure, and slicing knives for cattle substituted when desired.

Fig. 1. A. Face side of disc.
B. The bar to which the knives G are fastened with a screw, each one separately.
C. The three bolts which fasten the bar to the disc.
D. The face plate or guard which the teeth F of the disc approach near enough to prevent the escape of the last piece.
E. The last piece.
B. E. and F. of Fig. 2 are the same as on Fig. 1.

HORNSBY AND SONS' NEW TURNIP CUTTER.

FIG. 1.

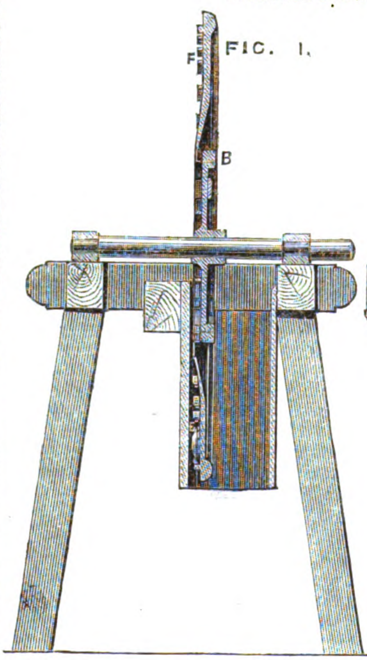

FIG. 2.

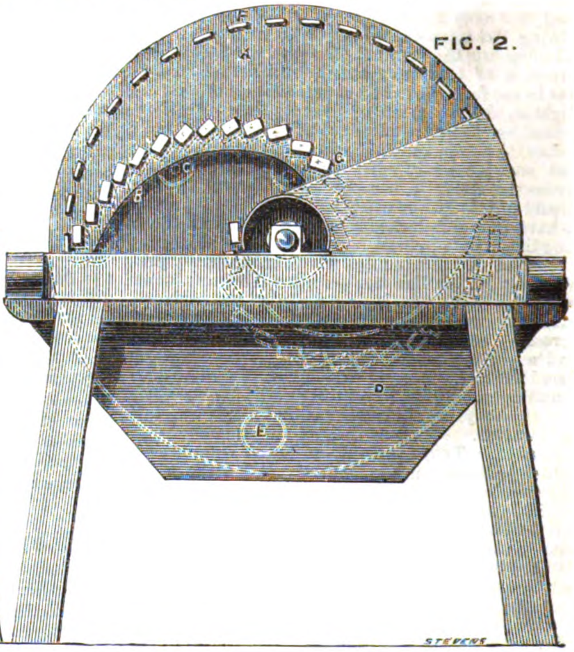
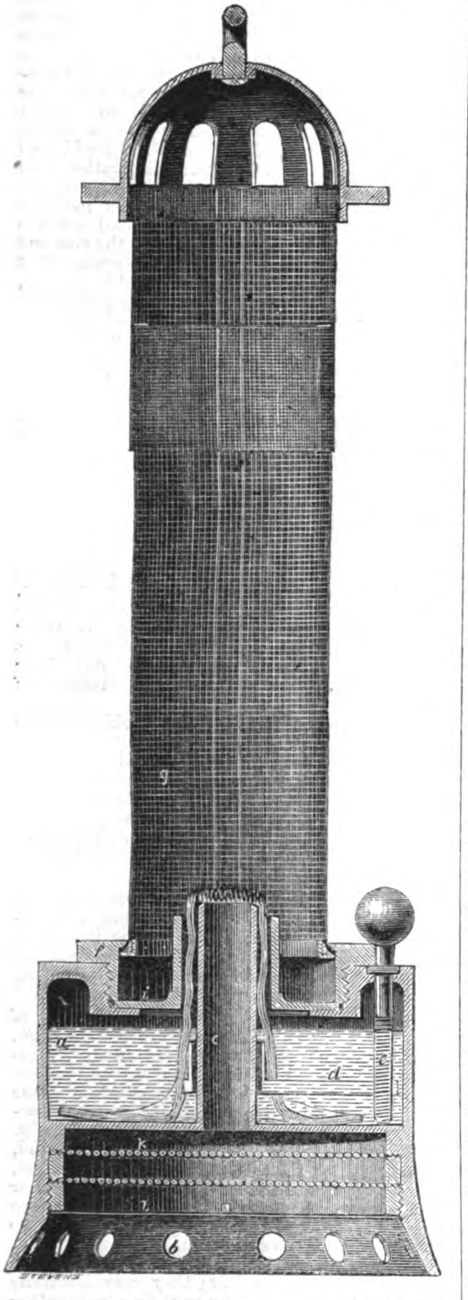


We last year published a review, and have since given extracts from Truran's valuable work on the iron manufacture. At Dowlais Ironworks, where Mr. Truran was employed, the weekly make of iron is about 130 tons, and the ordinary weekly amount of slag, 250 tons. The materials delivered weekly at the top of the furnaces would occupy 1,066 cubic yards. The air delivered in the same time by the tuyeres (*i.e.* the nozzles of the blast apparatus) weighs 1,695 tons and measures 50,550,400 cubic ft. Each ton of iron is reduced by 43·5 cwt. of carbon, and 388,800 cubic ft., or 13 tons of air. The weight of air is to the weight of material added at the top, as sixteen to seven. For each ton of liquid matter obtained (that is, including both iron and slag), no less than 129 cwt. of gases are evolved from the furnace.

HOWDEN AND THRESH'S SAFETY LAMP.



From our own experience we are inclined to assert that a great danger of the ordinary safety lamp consists in its giving such a poor light that the miner is continually tempted to open it, and obtain a light without the intermediate wire gauze. In the following lamp, as shown in vertical section, a hollow wick, upon the famous Argand principle, is used, whereby, of course, a much brighter flame is produced.

Instead of the ordinary solid wick, a tubular wick is used, making an air supply through the oil-chamber or reservoir as in the ordinary Argand lamp. Below the central opening in the oil-chamber are placed wire gauze diaphragms, set at a short distance apart, for the purpose of cutting off the communication between the interior of the lamp and the outer atmosphere. In other respects the lamp is very similar to those generally in use.

a a is the oil-chamber, the sides of which are continued downwards to form the foot of the lamp. A ring of holes, *b b b*, is made around the foot of the lamp to ensure access of air to the interior; *c* is an open tube extending upwards through the oil-chamber to near the level of the wick. Concentric with this tube is a wick-holder *d*, which is raised and lowered as desired by an adjusting screw *e*, which is supported by a shoulder fitting into the top of the oil-chamber. The middle part of the top of this chamber is recessed, and the edge of the recess has a screw cut upon it to enable it to receive a screwed collar *f*, which carries the upper part or cover of the lamp that surrounds and encloses the flame. This cover is composed, as usual, of a wire gauze cylinder *g*, with strengthening rods, and a cap *h*, to which the suspending ring is attached. Between the collar *f* and the top of the oil-chamber the nozzle *i* is secured, which with the tube *c* forms an annular space for the wick to pass up. The wire gauze diaphragms are shown at *k k*, situate immediately below the oil-chamber, and divided from each other by a loose metal collar. These diaphragms are held securely in place by means of a threaded ring *l*, which screws into a thread cut on the inner face of the foot of the lamp. Access is gained to the wick and oil-chamber by detaching the upper part of the lamp from the lower in the usual manner.

It will now be understood that the air to supply combustion will, when the lamp is standing on the ground, enter the holes *b* at the foot of the lamp, pass through the diaphragms, and up the central tube *c* to the flame. An ample supply of air will thus be ensured to the flame sufficient to keep up a large bright light, while at the same time the possibility of the flame igniting fire-damp outside the lamp is effectually avoided.

RANSOME'S IMPROVED TRENAIL FOR FASTENING RAILWAY CHAIRS.

This invention, recently patented by Mr. A Ransome, of Ipswich, has for its object improvements in the manufacture of and in fastening railway chairs with wood trenails. For these purposes wood trenails are made, compressed, and are allowed to cool or set in moulds or dies, in which they are compressed as heretofore; they then drilled longitudinally from the head towards the point, but the lower part or point is left solid in order to admit of its being driven into a sleeper without injury. It is preferred that the hole thus drilled into a wood trenail should be cylindrical, in order to its receiving a cylindrical metal spike, which should fit the interior of the hole closely without requiring any considerable force to drive it in, it being desirable that the spike should derive its principal holding by the expansion of the trenail after it has been driven. It is desirable that the wood trenails made with solid points or lower ends as above described should be driven by the aid of a tool with a hollow face (corresponding with the curvature of the upper surface of the head of the trenail), which is placed on the top of the trenail when it is being driven. This tool is made with a projection on its under side, which fits the upper part of the hole in the trenail. In using these trenails to fasten railway chairs to sleepers the trenails are driven in through the holes in the base of each chair into the sleepers, the spikes are then introduced into the hole formed in the trenails, so that when the trenails expand in use the spikes will be more and more securely held, and the chairs will be better fastened to the sleepers than when using metal spikes alone, or wood trenails alone.

Fig. 1 of the accompanying engravings shows a longitudinal section of a trenail constructed according to this invention. *a* is the wood trenail bored to a sufficient depth to receive the metal spike *b*, the lower part of the trenail being left solid.

Fig. 2 shows a longitudinal section of a wood trenail, and the method of driving the same into the sleeper before introducing the spike. *a* is the wood trenail; *c* is the tool having a hollow face corresponding with the curvature of the upper surface of the head of the trenail, and a projection *d* on its under side, which fits the upper part of the hole in the trenail.

RANSOME'S IMPROVED TRENAIL FOR FASTENING RAILWAY CHAIRS.

FIG. 1.

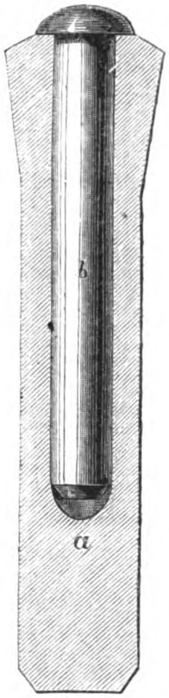


FIG. 2.

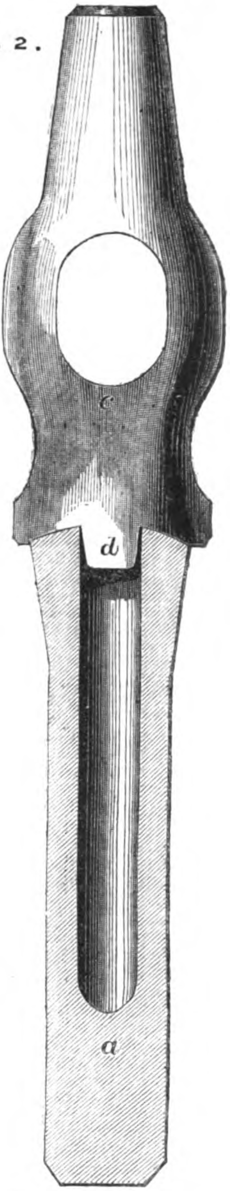

Messrs. Laird Brothers have just completed for Messrs. Cruse and Downham a new tug-vessel, called the "Columbus," fitted with a pair of their disconnecting diagonal engines, 90-horse power nominal. Speed being now a great object with tug-boats, as with all other ships, the "Columbus" was built to combine great speed with first-rate towing qualities, and on her first trial in smooth water she attained a speed of 14 knots, her engines indicating 7¼ times the nominal, or 650 effective horse-power. Her final trial took place on Thursday and Friday last, when she went to Holyhead and back. She accomplished the run, although she had considerable sea and wind to contend against, at an average rate of 12½ knots per hour, with a very moderate consumption of fuel. Messrs. Laird Brothers have built several vessels, and fitted them with engines of the same description as those on board the "Columbus." Some are at work in China, in Russia, and other parts of the world, and on the river Mersey. From their simplicity, these engines are kept in repair at a very moderate cost, and they are also very economical in fuel, and for these reasons they appear likely to be very generally adopted.—*Liverpool Daily Post.*

We are surprised not to see Mr. William Fairbairn's name amongst the newly baked batch of baronetcies. The honours of knighthood have been offered both to himself and to his son, and what is baronetcy but knighthood raised to the second power?

Meetings for the Week.

MON.—*Royal Inst.*, Special Meeting of Members, at 2 p.m.
London Inst., "On Sculpture," by R. Westmacott, Esq., R.A., at 7 p.m.

TUES.—*Inst. Civil Engineers*, "Discussion upon Mr. Preece's Paper on Railway Telegraphs, and the Application of Electricity to the Signalling and Working of Trains," at 8 p.m.
Royal Inst., "On Animal Mechanics," by Prof. Marshall, at 7 p.m.

WED.—*London Inst.*, Conversazione.
Soc. of Arts, "On Colonization and Convict Labour in the Hudson's Bay Territories," by A. K. Isbiter, M.A., at 8 p.m.

THUR.—*Royal Inst.*, "On Chemical Affinity," by Prof. Franklin, at 3 p.m.
Royal Soc., at 8.30 p.m.
Antiquaries, at 8.30 p.m.

FRI.—*London Inst.*, "On the Chemistry of the Non-Metallic Elements," by F. Field, Esq., at 7 p.m.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to M. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 6 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of his good faith.

RECEIVED.—Capt. C. C., J. N., T. S. S., Captain R. J. B., J. W., W. H. S., R. R., Admiral F. G. H., J. P., N. P. E.

COSMOPOLITAN (Chelsea).—"On Guns and Projectiles," will appear next week.

F. A. P.—The only way to protect an invention is by taking out a patent. After you had obtained the provisional protection, your invention would be then pretty well secured for six months.

J. D.—The secretary of the Northern Institute of Mining Engineers, is Mr. John Daglish, of Hatton.

F. S. (Brighton).—Thanks for your letter of the 11th and the information therein contained.

J. Y. BETTS (Coventry).—Your plan of constructing "the engine, so that its forepart should be of a wedge shape, as also the hand part of the guard's van," would not prevent a collision, nor would it much diminish the shock. More damage is often done by a train being thrown off the line than by a collision.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our Correspondents.*]

◆

STRENGTH OF IRON AND STEEL.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—As you have deemed my former remarks on Mr. Kirkaldy's work worthy of publication in your scientific journal, I am emboldened to make others on the same subject. I observe, that in a discussion which took place in the Institution of Scottish Engineers, on the 29th October last, as reported in your issue for January 2nd, the members present appear to have been at a loss to understand the effect of frost on iron, viz., how it happens that iron is more brittle in frosty weather than in summer.

There has never appeared to me any difficulty in accounting for this. Iron melts at a certain temperature; it is easily hammered into any shape at a lower temperature when colder still; it yet retains a portion of its ductability, but is not, by any means, so readily worked. In short, the less heat is added to it, the less ductile and the more brittle does it become.

Herein is the whole simple explanation, why, in frosty weather, iron tires so readily snap. A brass or gun metal band ¼ or ⅛ in. smaller than the extreme size of the iron wheel might be put on. Reasoning by analogy, we would arrive at the conclusion, that there is a point of low temperature where iron would lose all cohesive force and crumble to pieces; and if iron, then why not everything else on this earth which becomes brittle by want of heat.

I am, &c.,
CHAS. BATHOE.

28, York-place, Portman-square,
Jan. 10, 1863.

REPAIRING THE "GREAT EASTERN."

SIR,—I noticed in your journal of Jan. 9th, a long account, extracted from the *Scientific American*, of the plan employed in repairing the damage done to the "Great Eastern," whilst afloat, and I also observe that it is termed an "extraordinary feat of hydraulic and mechanical engineering."

It may, perhaps, be interesting to the writer in the *Scientific American*, to know that this identical contrivance was described just 40 years ago, and if he will refer to vol. 40 of the "Transactions of the Society of Arts," he will find an engraving and description of it.

It was invented by a Mr. W. Hookey, to enable the under-water portions of a ship to be repaired whilst the vessel was afloat, and thus avoid the loss of time caused by docking. It is amusing to see the resuscitation of this plan after an unknown existence of 40 years.

I am, &c.,
CHAS. F. T. YOUNG, C.E.

7, Duke-street, Adelphi,
Jan. 10, 1863.

INTERNATIONAL AGRICULTURAL EXHIBITION AT HAMBURG.

SIR,—An International Agricultural Exhibition is to be opened at Hamburg on the 14th of July, 1863, for the space of one week.

The very accessible situation of Hamburg, both by land and sea, renders it a most convenient place for an exhibition of this nature, and it is hoped that English agriculturists and manufacturers of agricultural implements will heartily co-operate towards the success of the undertaking.

The committee are making exertions to induce all steam navigation and railroad companies to convey at reduced rates of freight live stock, machinery, agricultural implements, and produce, that may be destined for the Exhibition. Their endeavours have not yet terminated, but, so far, every encouragement to this end has been held out to them, and they will not fail to make generally known their arrangements as early as possible for the information of exhibitors.

The articles exhibited will be exempted from duties, and the usual Customs' regulations will, in their case, be suspended.

The committee have secured the hearty co-operation of the German Agricultural Society; they are liberally supported by the Hamburg authorities and other Governments; indeed, so many agricultural societies in different countries, especially the Royal Agricultural Society of Great Britain, have evinced such a warm interest in this the first undertaking of the kind in Germany, that the committee are encouraged to use their most strenuous efforts to render the Hamburg International Agricultural Meeting of 1863 memorable for its importance.

All prizes are open to general competition.

Applications must be made on or before the 1st of May, 1863, to the Secretary,

GERHARD HACHMAN, LL.D.,
Hamburgh.

Hanseatic Consulate General,
12, Austinfriars, London.

THE AUSTRIAN AND PRUSSIAN PATENT LAWS.

SIR,—Having read with great interest an article on "Patent Law Reform," that appeared in your Number for Jan. 2, perhaps the following observations on the working of the Austrian and Prussian patent laws may not be deemed inacceptable to your readers:—

The Austrian law of 1852 was framed by men possessing an intimate knowledge of the then state ot the empire, and who were desirous of prefacing the intended introduction, in 1860, of the freedom of trades and of labour. From 1852 to 1860, the law was of the very greatest benefit to the industry of the empire, from the facility of obtaining a patent, its extreme cheapness, and the fact of its rendering the holder free of the Guilds and of their heavy taxes. Since 1860 the number of patents granted yearly has increased, as trade and manufactures in Austria have, since 1860, also increased in an accelerated ratio.

On the other hand, the protection against piracy is still too slight, and, in most cases, a patentee prefers *not* to prosecute at all, rather than to risk the costs of an action in a province distant from the capital, or from that part of the country where he is himself residing. This arises, not so much from the *wording* of the law (which is very stringent as to putting down piracy, but, nevertheless, gives no damages unless the piracy be repeated), but from the fact of any piracy having to be judged by experts chosen by the court of law; which experts seldom understand the nature of the invention itself, and often decide more from local partiality, rather than according to the merits of the case. I repeat, the wording of the law and its effects upon industry have been excellent, but the law is carried out too laxly. The patents being granted at the risk and peril of the applicant, it often happens that inventions are patented over again. Again, medicines and edibles are stated as not patentable by law, yet medicine and food patented in other countries are advertised daily in the newspapers. It is true, however, that the College of Medicine brings frequent actions to stop such sales, and the vendors, very generally, have to pay a fine.

A very large number of the patents granted are worked out I should say, about 40 per cent., and of these, from 16 to 20 per cent., pay; in some cases very well.

Nearly 60 per cent. of the Austrian patents are for inventions connected with mechanics.

The Registration of Samples and Designs, which was instituted in Austria in 1858, affords, for the small charge of five florins, a protection for three years. This is merely for a novel design, pattern, or form, of something in general use, and the registration is made at another office, and is under another administration than that of the patent office itself, which is a branch of the Ministry of the Interior. It was, formerly, under the Ministry of Finance.

The following account of the working of the Prussian patent law was mainly translated from the letter of a valued correspondent in Berlin:—

I must first state, that no special law concerning patents exists in Prussia, but all patents are judged and determined according to a decree (Publicandum), dated Oct. 14, 1815, from Paris. This Publicandum, given below, is not even inserted in the collection of laws (gesetzsammlung).

The way of transacting the business is this:—A permanent committee of five members is entrusted with the examination of the invention. They are assisted in their work by reference to a first-rate library, and the use of every existing periodical on commerce, mechanics, and science.

The granting a patent depends upon the novelty of the invention, whether the principle itself (prinzip), the improvement, or even the arrangement, especially in the case of machines, be considered as new.

The committee lays before the Minister their opinion of the invention, which is, as a rule, accepted by the Minister, and carried out accordingly.

The committee acts with extreme caution; and, as they consider themselves, to a certain extent, answerable for their votes, no small invention, or minor improvement, ever obtains a patent. As no higher court of appeal exists, any applicant has to rest satisfied with the decision.

Foreigners, in particular, feel most severely this utter want of a proper law; they very naturally secure their inventions first in their own country; it happens, therefore, very often that the invention comes to the knowledge of the committee sooner than the application for a Prussian patent, either by means of periodicals, a description of foreign patents, or more particularly by the publications of the English Patent Office. And, as novelty in invention is the only thing which can be patented, it follows that a patent is at once refused, and without power of appeal.

My experience tells me that this defective state of the law, and which was not even suited to the last century, acts most deleteriously on our industry. No one will take the trouble to make or carry out inventions, unless they can look forward to some reward or profit; and if, notwithstanding this, there are still parties who apply for patents in Prussia, it is only those who have not as yet endured the annoyance of a refusal. Consequently, no one endeavours to make or carry out inventions or improvements, but, having one of importance, takes it to foreign countries. Very often I have heard foreigners say, that they would come to Prussia or Berlin itself, to establish themselves, as soon as the patent for their invention be granted. The patent being refused, the foreigner remained in his own country, where the rights of intellectual property are under better protection than in Prussia, which, notwithstanding, is considered the seat of intelligence, *par excellence.*

I am, &c.,

Vienna. EDWARD ALFRED PAGET.

N.B.—Prussian patents are only granted to resident members of the Guilds.

THE WATER-GLASS BAROMETER.

SIR,—This simple apparatus, which I have myself used for nine months, and which is described by Mr. Copland, in the *Times,* was invented upwards of two hundred years since! I have found it, in general, more correct than the barometer.

1. The water rises *higher* with *cold* winds than it does with those which are *warm.*

2. The water rises *higher,* and then falls *lower,* before *snow* than it does before *rain.*

3. The water rises for some days (but always for some time) before the *change* of the weather, whether for snow or rain.

4. If presently *falls* again, even before the rain or snow falls.

5. When the *rain* is likely to be of a long duration, and accompanied with *heavy gales,* the water will be very *low* in the tube, and will be *indented* or *concave.* This generally takes place *eight* hours previously.

6. When the water is *high* in the tube. I invariably find that if the *hand* laid on the top of the bulb does *not* cause the water in the tube to *descend,* that no change in the weather will follow for twelve hours or more.

N.B.—The changes in this water-glass barometer will be beneficially studied by invalids, and more especially by those afflicted with epilepsy, and other nervous disorders, which are always more prevalent with a low state of this barometer—*anti-periodic* medicines being called for when this is observed. My glass is graduated similar to Mr. Copland's, and is furnished, moreover, with a very small thermometer attached to a *float,* which rises and sinks with the water. I am, &c.,

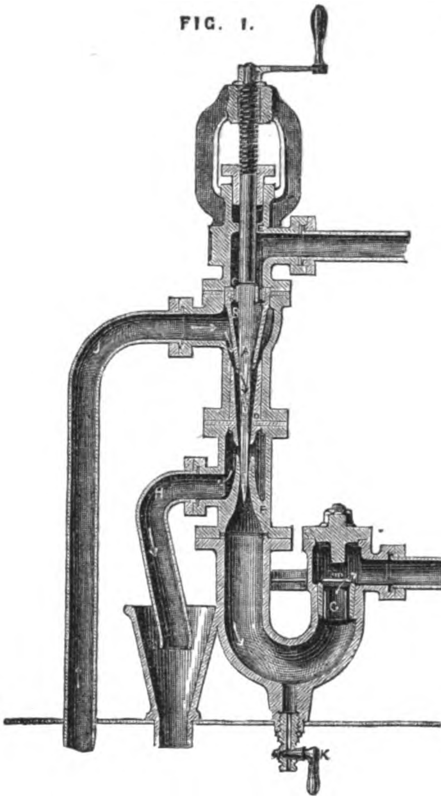
JAMES BRUCE.

1st January, 1863.

PS.—The following is a description of this weather-glass taken from a very old and scarce work:—"Procure at the glass-house a globular glass, with a tube or pipe thereto proportionable, whereof there are many sizes; but be sure let not the head be too big, nor the pipe too short, lest there be not rise enough in the winter, or fall enough in the summer. You must also have a small glass, or vessel, at the bottom, that may contain water enough to fill the tube, or more. Then, having fixed them in some frame made for that purpose, *heat the globe of the glass with a warm cloth, to rarify the air within it,* and then put the end of the tube into the lower vessel, and it will attract the water, more or less, as you warmed the head. You may also add numbers on the glass, to shew you the degrees. The water you may colour blue, with Roman vitriol boiled, or red, with dried rose leaves, and imbibed in fair water, wherein a little oil of vitriol, or spirit of salt, is dropped. With this water fill the under vessel, which, being rightly placed on the *north* side of your house, where the sun rarely, or never, shines against it, and in a room without any fire in it, lest the sudden access of heat, or accidental alteration of the air, might impede your observations. The air included within the globe, or ball, of this glass doth admit of dilation and contraction equally with the ambient air, that whensoever the ambient air is dilated or expanded, either through the heat of the season, or before the fall of rain, &c. The air in the glass is the same, and as, by its expansion, it requires more room, so doth it let the water in the tube descend gradually; or, as it is more dense or contracted, either through the coldness of the season, or the serenity or inclinability to draught of the ambient air, so also doth the air within the glass contract itself in a less compass, and sucketh up the water in the tube gradually, as it condenseth or contracteth; whence you may at any time know the very degree of rarity or density of the ambient air, by that which is included in the glass, and thereby inform yourself what weather is most likely to suceeed at any time. Be sure to quadrate or contemporise your observations or numbers of degrees with the season of the year; for that degree of rarity which signifies rain in the winter, may be such a degree of density that may signify fair weather in the summer. The differences betwixt the highest rise and the lowest fall in one day in the summer, is much more than in the winter; for you shall have a cold night and very serene air, which contracteth the air in the glass into a small space. after which usually succeeds a very hot day, which dilateth it very much; when in the winter no such great difference happens in one day. Yet in the winter, in several days, will the difference be as great as in several summer days. Although the air appears serene and cold to your senses, yet trust not to that, if the glass signify otherwise."

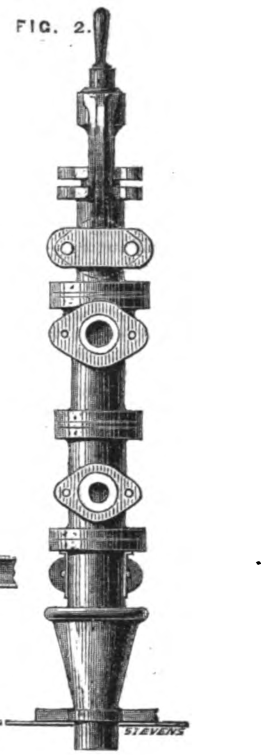
PRADEL'S IMPROVED INJECTOR.

FIG. 1.



SECTION.

FIG. 2.



END VIEW.

AN IMPROVED INJECTOR.

THE accompanying engravings show a modification of that remarkable feed apparatus, the Giffard injector. This plan has been introduced on to the injectors used on the Lyons Railway, France, by Monsieur Pradel, the "Sous-chef de traction" of that line. The engravings show to one-twelfth scale, an injector intended to feed 120 litres of water per minute. The steam entering by the pipe *b*, circulates round the cone *a*, whence it issues in the shape of a circular jet into the chamber *d*. The steam, by its motion, carries with it the air contained in the pipe *j*, and consequently draws up the water, which, surrounding the cone *b*, condenses the steam on its arrival. The water then passes successively through the chamber *d*, and through *f*, and lifting up the clack valve *g*, the water enters the boiler. The pipe *h* is for receiving the condensed water formed on starting or stopping the apparatus.

Gossip.

M. Regnault has described a method of recording the temperature and pressure in balloon ascents, without observation of the aëronaut. The apparatus consists of a series of tubular reservoirs, with capillary tubes proceeding from them; at the end of each capillary tube a larger tube, filled with chloride of calcium, is fixed, so that only dry air can enter the reservoir. These constitute the thermometric system. The barometric consists of a similar series, with their reservoirs immersed in melting ice. In order to insure the temperature of the ice remaining constant in the extreme cold of the upper regions, it is recommended to surround the vessel containing the ice with another vessel containing warm water at starting. The tubes are numbered to correspond in each series. To determine the temperature and pressure at any moment, it is necessary to close the stop-cocks of one tube in each series simultaneously, the balloon not being in rapid motion at the time. The density of the air contained in the tubes is afterwards determined, from which both the temperature and pressure at the time of closing can be deduced.—*Popular Science Review.*

At the last November meeting of the Franklin Institute, Philadelphia, Mr. Howson exhibited a family Bible, in which, adjacent to the pages usually bound in the book for the registration of births, deaths, &c., were arranged in sheets any convenient number of card cases, such as contain the ordinary photographic albums, and in which could be inserted the photographs of the different members of the family.

Several French papers assert that the French Emperor is bringing out an electro-magnetic engine. It is being made at a well-known Parisian engine builders' shop, and sanguine hopes are entertained that it "will give out a double or treble force to that of the steam-engine." We suspect that Napoleon will find that it is easier to upset a republic, or uphold a Pope, than to dethrone King Steam.

The cotton wads with which engineers clean their machinery are afterwards worked up into some descriptions of shoddy. Cotton waste, often used for the same purpose, is manufactured into writing and printing paper; whilst in America it is made into an imitation of papier maché.

Louis Gover, 40, electro-plater, was indicted for feloniously having in his possession certain instruments for the manufacture of counterfeit coin.—Brennan, inspecting officer to the Mint, went, accompanied by several police officers, to the residence of the prisoner in a retired place known as Leslie's-gardens, Bermondsey. The house consisted of three rooms, one above another, and on Brennan reaching the top room he found two galvanic batteries properly charged with acids, ladles with white metals recently fused, files, plaster of Paris, antimony, sand, and all the usual implements used by the makers of counterfeit coin.—The jury found the prisoner guilty, but the Common Serjeant deferred passing sentence, in order that the opinion of the Court for Crown Cases Reserved might be taken as to whether the galvanic batteries found on the prisoner's premises came within the definition of the 24th section of the 24th and 25th Victoria, viz., "a machine" for the making of counterfeit coin.—Sentence was accordingly deferred.

On Wednesday week the last rivet in the Londonderry Iron-bridge, was secured by the chairman of the bridge commissioners, assisted by Mr. John Hughes, C.E., resident-engineer, and Mr. Matthew Pitts, representative of the contractors. This bridge is 4,200 ft. long, and has been twelve months in erection. Messrs. Butler, of Stanningley, were the contractors.

An extensive series of experiments is about to be made in France with the typo-telegraph invented by M. Bonelli, by which 500 despatches, of 25 words each, can be printed within an hour. Should the experiments prove satisfactory, it is intended to introduce this telegraph on the principal railway lines in France.

Among the many new companies that the plethoric state of the money market is creating, one of a most novel and curious nature is talked of. The object is to construct a gigantic reflecting telescope, of far greater dimensions than Lord Rosse's celebrated 6 ft. reflector, with which it is expected wonderful planetary sights will be revealed.

Mr. Robert Aytoun, the inventor of a well-known safety-cage for miners, has proposed a new safety-break for railway trains to the Scottish Society of Arts. He suggests to fix to the sleepers, between the rails, a longitudinal strip of timber, 5 in. square, to be compressed by a pair of compound bladed springs, of any requisite amount of power affixed beneath the break-van, and under the command of the guard. This would be rather an expensive plan for a long line of railway.

A phenomenon, observed within the last few days at Varages (Varr), would seem to indicate that the recent sudden changes in the weather in the south of France have been accompanied by some disturbances below the surface of the earth. A fine spring, which from time immemorial had supplied the above-named village with water, last week suddenly poured fourth a stream of water entirely black and extremely nauseous. This continued for three days, when the water began to clear, and is now as limpid and as sweet as ever.

The mill-owners in England, generally, have ordered their mill-girls to leave crinoline outside the walls. It is said that gentlewomen lose their lives at the rate of 750 per annum through their skirts catching fire. If the ladies will not render their dresses fire-proof by means of chemistry, why don't they take to mechanics, and "box off" the fire with wire guards?

In the Geological Museum there is a lump of silver—about as much as would make 40s.—which has been taken from the stomach of a mule in Mexico. It appears to be a common occurrence to find quantities of silver in the the stomach and intestines of the mules working in the Mexican silver mines, and its presence is accounted for by the mules eating mud, which contains much silver, for the purpose of obtaining the salt which is mixed up with it also. The silver is said to accumulate to a considerable extent without proving injurious.

Of oakum made from old ropes, Mr. Simmonds states that 1,400 tons, valued at £28,000, are sold annually in Liverpool. The total imports of codilla or tow (the waste fibres which occur in the cleansing of hemp and flax), amounted in 1857 to 13,000 tons, valued at £373,000. It is manufactured into bags, yarn, &c.

A gun built entirely of steel, and composed of several tubes of that metal, put together in the method introduced in France by Colonel Trenillee de Beaulieu, but better known in England as "Blakeley's" plan, and which secures the simultaneous action of all the tubes in resisting the bursting force of the powder, has been recently tried in that country. The gun weighs only 4¾ tons and a few pounds, or nearly 3 tons less than the Armstrong gun rifled on the Whitworth plan. The French gun is rifled with three grooves, less than a quarter of an inch deep. The twist of the rifling is uniform, one turn in 30 calibres, being a slightly quicker turn than that used by Armstrong, and a little slower than that used by Cavalli and Whitworth. The gun, when last heard of, had been fired 800 times without injury. The shell weighs 45 kilogrammes or between 99 lb. and 100 lb. The service charge of powder is 12½ kilogrammes, or about 28 lb., although in some cases 15 kilogrammes, or 33 lb. of powder, were fired. With reference to the question of the introduction of flat-headed projectiles, it is scarcely perhaps necessary to mention that they were first brought into public notice by Captain Norton in 1852, and were described by him as "punch-headed iron shells." The gallant captain, with more modesty than other inventors, did not, however, claim for his shell the advantage of novelty, but only the method of rendering it applicable to modern artillery. The Austrians are said to be using for their cannon an alloy called Aich metal, from the name of the inventor, and composed of copper 600 parts, zinc 382 parts, and iron 18 parts. Its tenacity and toughness are said to be very great.

The trade in petroleum or American rock oil continues to increase with extraordinary rapidity, and promises to become of so much profit and importance to the country as to render it essential that the commercial public should not allow the business in it to be needlessly restricted by vague alarm as to danger attending its storage. According to a circular of Mr. Macrae, a Liverpool dealer, although the American oil was almost unknown in 1860, a total of 9,000,000 gallons was imported into Europe in 1862, and not one disaster happened in connexion either with its transit or storage which would not equally have occurred to any other article of production. Recent advices from Belgium assert that the Minister of the Interior has just taken occasion expressly to declare that this oil is not to be considered as one of the articles of inflammable merchandise which must be treated by special regulations as essentially dangerous.

A Trieste letter in the *Frankfurter Journal* says:—"The first merchant steam vessel built here has just been completed. It measures 1,000 tons, and has been constructed by M. Tonello, who has the intention of building five others still larger, and competing with the English line of steamers between Liverpool and Trieste. M. Tonello affirms that there are few maritime places in Europe where the construction ot vessels can be carried on at less expense than at Trieste."

M. Brachet has proposed as an improvement, in applying the electric light, to inclose the light within a globe of uranium glass, and that again within a second glass globe, of such a colour as to correct the greenish tone of the resulting light: and the proposal has been referred to MM. Regnault and Babinet for consideration.

ALUMINIUM BRONZE.—In the supplementary number to vol. 24 of the *Philosophical Magazine*, just published, we find a remarkable article, by Lieutenant-Colonel A. Strange, F.R.A.S., on the properties and present value of aluminium bronze, an alloy consisting of ten parts of aluminium and 90 of copper. Its tensile strength is stated at 73,185 lb. per square inch, being more than double the breaking strain of gun-metal, and 1,185 lb. more than the avarage tenacity of cast steel. Its resistance to compression is 132,416 lb. to the square inch; that of cast iron being 115,542 lb. As to malleability, this alloy may be drawn out under the hammer almost to a needle point at a red heat. Its rigidity is about three times that of gun-metal, and 44 times that of brass; it is less affected by change of temperature than either of the latter; it may be cast with extraordinary facility into any shape; it does not clog the file, and yields fine elastic shavings on the lathe. It tarnishes much less readily in the air than any other metal or alloy used for astronomical instruments, and will receive the finest graduation possible. It is extremely elastic, can be rolled into sheet metal, or also hammered and drawn, and seems admirably adapted for the tubular parts of astronomical instruments. Its specific gravity is 7·689, nearly the same as wrought iron. To make this alloy extremely pure copper should be used; the best is copper deposited by electricity; but, since that kind is very expensive, the next best is copper from Lake Superior, which makes an alloy of an excellent quality. The ordinary coppers of commerce generally fail, owing, it is said, chiefly to the presence of iron, which appears to be specially prejudicial. Another precaution is to remelt the alloy two or three times. The first melting, in the proportions above stated, produces an alloy of extreme brittleness; but each successive melting, up to a certain point determined by the working, and particularly the forging properties of the metal, improves its tenacity and strength. The present price of English made, 10 per cent. Aluminium bronze is 6s. 6d. per lb., or four or five times the price of gun metal; but as a much smaller quantity of the new alloy would give the same strength, the cost of ordnance made of it would not be very considerably increased.—*Galignani's Messenger.*

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 1789.
BOILERS AND FURNACES, 1769, 1779, 1805.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1809, 1795.
SHIPS AND BOATS, including their fittings, 1782.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 1784, 1788, 1793, 1799.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1765.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1772, 1781, 1797, 1806, 1808.
BUILDINGS AND BUILDING MATERIALS—*none.*
LIGHTING, HEATING, AND VENTILATING, 1774, 1777, 1783, 1785.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1768, 1771, 1775, 1791, 1794, 1804.
METALS, including apparatus for their manufacture, 1767, 1787, 1790.
CHEMISTRY AND PHOTOGRAPHY—*none.*
ELECTRICAL APPARATUS, 1778, 1801.
WARFARE, 1763, 1764, 1792, 1796, 1798, 1807.
LETTER-PRESS PRINTING—*none.*
MISCELLANEOUS, 1766, 1770, 1773, 1776, 1780, 1786, 1800, 1802, 1803.

1763. W. E. NEWTON. *Improvements in firearms, and in the attachment of bayonets or swords thereto.* (A communication.) Dated June 13, 1862.

This relates, 1, to breech-loading firearms, and consists in effecting the connection of a moveable breech, which opens and closes by an upward and downward swinging movement on a pin passing transversely through the arm, with a lever mounted under the stock by means of two pins, one of which is attached rigidly to the bottom of the breech, and is arranged lengthwise of the arm. A sliding collar is also applied on the first pin, and is pressed forward against the second one by a spring placed in rear of it, such spring holding the breech open after it has been opened by the movement of the lever, and while the arm is being loaded. The second part of the invention relates to the mode of applying and operating a device for withdrawing the discharged cartridge cases in a rearward direction from the barrel of the firearm. The third part of the invention consists in applying the hammer, the tumbler, and the spindle or arbor to which they are attached in the metal frame of the stock of a firearm, whereby the lock is enabled to be made very strong without cutting away and weakening the stock to such an extent as is done in many firearms. The fourth part of the invention consists in the attachment of a bayonet or sword to a firearm by means of a pivot joint, which permits it to be brought from the position known as "fixed" to a position close under the stock. *Patent completed.*

1764. W. E. NEWTON. *An improvement in elongated bullets.* (A communication.) Dated June 13, 1862.

This consists in the combination with an elongated expanding bullet of a headed pin, and a concave expanding disc, the disc having its concave side against the base of the bullet, and the pin entering the cavity thereof, and operating to produce the flattening of the disc, by which the latter is caused to expand against the walls of, and enter the rifle grooves of, the gun, for the purpose of preventing windage, and obtaining for the bullet a rotary motion on its axis. Also in making the pin and the cavity of the bullet of a conical form, in order to reproduce the expansion of the cylindrical portion of the exterior thereof at the forward part. By making the front end of the pin conical, the cylindrical portion of the bullet will be first expanded, thus causing the friction against the bore of the gun to begin as far forward as the bullet shall bear against the bore, by which the bullet will be more quickly and perfectly upset, its friction will be more easily distributed, and its centre of gravity made more evenly to coincide with the centre of the bore of the gun, all of which conditions are necessary to accurate shooting. *Patent completed.*

1765. J. IVES. *Improved apparatus for expressing juice from fruit and other vegetable substances.* Dated June 13, 1862.

This consists principally in the use of elastic rollers for crushing the fruit, &c., and expressing the juice. *Patent abandoned.*

1766. J. ROBINSON. *Improvements in machinery or apparatus for sawing wood.* Dated June 13, 1862.

This relates to machines called timber and deal frames, and consists in so constructing and arranging them as to cause the whole of the feed to take place during the upward motion of the same. *Patent completed.*

1767. J. LANCELOTT. *Improvements in the manufacture of ornamental chains from sheet metal.* Dated June 14, 1862.

This relates to the forming of chains from punched blanks of peculiar construction, each link being formed of two separate blanks of different form, which blanks are afterwards soldered together and so united. The invention is not described apart from the drawings. *Patent completed.*

1768. T. Williams and H. Cox. *Improvements in churns, partly applicable to washing machines.* Dated June 14, 1862.

Here the patentees provide the lower part of the case or body of the churn with a chamber or chambers distinct from the interior of the churn, the said chamber or chambers having an opening or openings communicating therewith, so as to admit of cold or hot water or liquid being poured therein; an orifice with plug for stopping the same as is used for drawing off this water or liquid. To withdraw the milk there is an orifice as at present sometimes used in churns at or near the bottom, the same being stopped by a plug when not used for drawing off, the butter being taken out from the top. In the interior of the churn they use beaters adapted thereto, which they prefer to set slantwise, so as to churn with greater effect. These beaters are framed together, and they prefer to secure the same to the base by pivots, one of these pivots passing through a stuffing box, the same being an axle pivot, and having attached thereto special arrangements for working the beaters. *Patent completed.*

1769. J. Sawyer and G. Padgham. *Improvements in steam boiler and other furnaces, applicable in part to grates of various kinds.* Dated June 14, 1862.

An important feature in this invention is the use of firebars each of which is curved in the upper as well as the under surface thereof, each of such bars having projections at each side, so that when one bar is put in position by the side of another, these projections may fit or nearly fit against each other, leaving openings between them, producing in effect a number of air tubes or passages, admitting the air to the fuel in the furnace to assist in the more effectual combustion of the said fuel. The invention also comprises improvements in the fire-bridge and furnace door. *Patent completed.*

1770. J. G. A. Dallot. *A new portable circular saw.* Dated June 14, 1862.

This saw is mounted on points, as also the shaft of the saw and the fly-wheel, and by this means less power is required than if mounted on bearings. The points may be made either on the shaft or on the screws on which turns the shaft of the saw. Motion is communicated by a crank to a toothed wheel, thence to a second wheel, which communicates it to a fly-wheel placed on the saw shaft. This is the method the inventor prefers, but the fly-wheel may be placed on the driving shaft, and the driving gear be more or less complicated. This description of saw is set on a frame or table, the toothed gearing on the side at one end, and the fly-wheel on the side in the centre, and commanding the saw which is in the centre of the table, and placed so as to present nearly half its diameter above the level of the table. On the top of the table is an iron or wooden regulator for directing the wood, so as to give the size desired. The top of the table is moveable, and is raised either at one end by a screw, or horizontally by screws, with rag chain, or otherwise. The lifting of the table top or board gives the facility of making rebates, grooves, tenons, and similar work. Saws may also be constructed on this method with two cranks, rag wheel, and chain-driving band or toothed gearing. *Patent abandoned.*

1771. J. F. Miguel. *An improved pessary.* Dated June 14, 1862.

This is composed of caoutchouc, or other elastic material; it is oblong, and varies in lenth from 2 in. to 5 in.; it is longer in the middle than at its ends, which are cut straight, their edges, and all the edges of the pessary, being rounded; the thickness also varies between about ¼ in. and 1 in. The centre of the pessary is pierced with an elliptic hole, varying in diameter according to the state of the parts which it is to lift and fix, and each extremity is furnished with a handle of strong silken thread, varying from 7 in. to 8 in. in length. This retentive apparatus is introduced by one of its extremities into the vagina towards one of the sides, and the other is pushed against the opposite side, so that it rests in front of the ischunin. There are other details. *Patent abandoned.*

1772. J. H. Johnson. *Improvements in Jacquard machines.* (A communication.) Dated June 14, 1862.

This relates to a peculiar construction and arrangement of certain parts of Jacquard machines, and to a mode of operating the same, whereby a considerable economy in the number of cards is effected by causing each card to serve four strokes of the cylinder or prism, in lieu of only one. According to this invention, the prism, or cylinder, is so built up or constructed as to admit of that portion which carries the card pins or studs being slid laterally by a rod or spindle acted upon by an eccentric or otherwise, and inserted into one end of the cylinder, suitable springs being used inside the cylinder for returning the pins to their places again when the action of the rod ceases. The surfaces of the cylinder, or prism, are provided with a series of grooves, or channels, made transversely across each face, in substitution for the perforations hitherto used. The cards have each four different sets of holes punched therein, and, after the first stroke of the cylinder, the ends of the needles are slightly elevated, so as to bring them opposite a second set of perforations for the second stroke. Previous to the third stroke, the card is moved longitudinally along the cylinder, or prism, as before stated, which has the effect of bringing the third set of perforations opposite the needles, and the fourth set of perforations are brought into action by lowering the needles again to their original position before making the last stroke, after which the cylinder is rotated one quarter turn, so as to bring a fresh card into action. *Patent abandoned.*

1773. W. Bouch. *Improvements in cranes.* Dated June 14, 1862.

This invention applies chiefly to those machines known as "accident cranes," and which are fixed on trucks for use on railways. This invention consists in constructing cranes as hereafter stated:—The patentee connects the inner end of the jib to an axis, on which it is free to be moved, to alter its inclination, without altering the angle of the castor wheel. He attaches to the top, or outer end of the jib, by universal joints, two legs, one on each side of the jib. When the crane is out of use, these legs are laid and carried horizontally; but when the crane is required for lifting or pulling heavy weights, they are brought to the ground, and afford support to the jib. He connects swinging bars and carrying bars to the rear of the crane, and fits to the latter, by means of rollers, or wheels, a counterbalance weight, the position of which is adjusted so as to bring it nearer or farther from the crane on the carrying bars, by means of a chain coiled upon a barrel, and worked by a worm and wheel. When the counter-balance is not required, it, together with the swinging and carrying bars, are drawn up into a vertical position. He attaches two short legs by universal joints, similar to those at the outer end of the jib, which are placed on each side of the truck, or vehicle, carrying the crane; these are to be used for affording support to the crane when lifting from the side. He also applies similar legs to each end of the crane, carriage, or truck, to prevent its moving when the crane is lifting or pulling from either end. *Patent completed.*

1774. R. A. Brooman. *Improvements in coking ovens in collecting and utilizing the products resulting from the distillation or carbonization of coal and other matters producing coke, and in apparatus employed therein.* (A communication.) Dated June 14, 1862.

This invention consists in the construction, arrangement, and working of coking ovens in manner hereafter described, whereby the following products are obtained during the manufacture of coke:—1, Coke suitable for metallurgical, railway, and other purposes, in greater proportion than when manufactured in the ordinary manner. 2, Gas suitable for burning and heating. 3, Tar, and different oils obtainable from it; and, 4, Ammonia and ammoniacal salts. The apparatus about to be described is not only applicable to ordinary coal, but also to anthracite, coke dust, peat, wood, and other combustible materials of vegetable or mineral origin, whether treated separately or mixed with rich coal, resins, or tars. Nine chief features are comprised in this invention. They consist, 1, In particular arrangements of carbonizing or coking ovens, capable of manufacturing coke from all kinds of coal. 2, In the application to these ovens of a continuous exhaust or draft for drawing off and collecting all volatile products resulting from the distillation of combustible matters. 3, In a method of condensing such of those products as are capable of being liquified, and in the proservation of each of such products, so as to utilize them. 4, In the application of gas produced in the ovens, whether to the heating of the furnaces of the coking ovens themselves or of other furnaces, or to the reduction of oxydized ores, or to any other purposes for which carburetted hydrogen can be employed, especially for lighting purposes. 5, In pulverising certain coals which would otherwise produce coke of a bad appearance, and ill adapted for metallurgical and railway purposes, whereas after pulverization of the coal, coke suitable for locomotives and other uses may be produced, and that without washing being necessary. 6, In mixing rich coal, tar, or resin, with poor coal, anthracite, coke-dust, peat, and other combustible materials, which do not by themselves produce good coke. 7, In the employment of steam thrown on the coke when at its highest temperature for desulphurizing it. 8, In the employment of apparatus, as hereafter described, for loading the apparatus with coal, and for removing the coke, whereby these operations are effected much more speedily and economically than in the ordinary manner. 9, In producing, in the same ovens as those used for the manufacture of coke, common tar, such as that obtained from gas works or other tars richer in oils, and in utilizing them in various ways.—*Patent completed.*

1775. W. Wighton. *Improvements in apparatus for regulating watches and other time keepers.* Dated June 14, 1862.

In carrying out this invention, the patentee attaches by arms to the ordinary regulator hand, a toothed quadrant, and causes a worm on a spindle to gear into the teeth of the quadrant. The spindle carries also a click or ratchet wheel for dividing the shifts, into the teeth of which a spring is made to drop at each shift with an audible click; the spindle terminates on the outer end in a square, and is moved by an ordinary watch key or other suitable instrument. He prefers that the teeth on the quadrant should be similar to those on a worm wheel. *Patent completed.*

1776. R. Hicks. *Improvements in the manufacture or preparation of paints, pigments, and colours.* Dated June 14, 1862.

The object here is for the useful employment of the debris or debritus obtained in slate quarries or slate works, in combination with any one of the known carbons or charcoals, such as lamp black, and such like matters, or of any of the substances containing sufficient carbon. These ingredients or schists or schistose substances, with the addition sometimes of oxide of iron or hematite iron ore, are intimately mixed together and subjected to the action of heat, whereby their chemical constitution becomes modified, so that when subsequently pulverized, they may be advantageously used as a paint, pigment, or colour. *Patent completed.*

1777. C. E. Courtillier. *Improved inhaling and saturating apparatus.* Dated June 16, 1862.

This consists in apparatus intended for inhaling vapour charged with medicinal substances; its utility is peculiarly conspicuous for the treatment of pneumonic diseases. It may also be of use as a purger of foul air in rooms. The apparatus consists of two recipients, which communicate together by an india-rubber pipe, supported by joining metallic tubes, and supported with cocks, the purpose of which, is to regulate or close any communication between both the receivers. The former, which the inventor calls a "generator," is placed above the flame of a spirit lamp, or upon any blaze or fire, and contains the water or medicated liquor to be vaporized; the steam passing through the india-rubber pipe gets into the latter, which he calls a "saturator;" it is of glass or metal, or any ceramic matters, and contains the medicinal mixture through which the steam devolves. On coming out of the medicated liquid, the vapour is sucked up into another india-rubber pipe or shank, tipped with a mouth-piece, allowing the sick person to inhale the steam saturated with medicinal principles. To the joining tube rising from the generator is adapted a small valve, which opens inwards to allow a small quantity of air to be introduced at every aspiration into the tube, in order thereby to facilitate the absorption into the stomach. *Patent abandoned.*

1778. T. M. Lanoa. *A geodetic and topographic instrument called Diastasimetre, intended to replace every one used in surveying.* Dated June 16, 1862.

The object of this invention is to combine in one all the instruments now used in surveying, and the instrument may be used for measuring distances from the shortest up to 500 yards or more, according to the power of the glasses or telescopes, for registering (with double register by rotation of the instrument or inversion of the glasses), for measuring inclines, and also for measuring horizontal angles, becoming in one moment, and without being dismounted, a graphometer and telescopic ring or circle. The improved instrument is composed of two glasses or telescopes—one fixed, the other moveable—a level, with air bubble and face at top and side, a graduated ring or circle, an alidade or cross staff set perpendicularly to the moveable telescope, adjusting apparatus to advance or retire the telescopes, adjusting screw for inclining the instrument, vice, and adjusting screw for advancing or retiring, and fixing the alidate, a socket supporting the instrument, the lower part of a rotula which permits the horizontal rotary motion being immediately above it, a screw serving to set the two parts of the horizontal movement, and a thumb nut to retain the instrument in a horizontal position. The instrument, which may rest upon a foot with three or six branches, possesses three distinct movements, namely, inclination backwards or forwards, right and left, until perpendicular, and horizontal rotation on its socket. *Patent abandoned.*

1779. J. F. Allan. *Improved furnace arrangements to prevent smoke and economise fuel.* Dated June 16, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1780. G. A. Birkbeck. *Improvements in the construction of presses for extracting liquids from various substances.* (A communication.) Dated June 16, 1862.

For the purposes of this invention, the body of the press in which the substances to be pressed are placed, is so constructed, that the use of bags or strainers may be dispensed with. This part of the press is of cylindrical, or other suitable form, with perforated sides enclosed by a strong ribbed frame, and closed by a moveable bottom, which, during the operation of pressing, is fixed in position, and, being also perforated, allows the liquid to pass away as the pressure is applied. The perforated bottom is, by preference, supported by a plate with channels to conduct the liquid to a central orifice. When the pressure of the piston is released, the moveable bottom can be readily withdrawn sideways by means of a screw lever, or other mechanical means, and the rake or residue of the pressed substance can then be readily discharged from the bottom of the press on to a platform, or into a suitable receptacle or carriage placed below to receive and remove it, thus saving considerable time in this operation. *Patent abandoned.*

1781. J. Evans. *Improvements in self-acting mules.* Dated June 16, 1862.

In carrying out this invention, the inventor, 1, Turns the twist shaft by means of a vertical shaft and pair of bevel wheels and catch or coupling box, instead of the driver, or counter straps at present employed. 2, He gives positive motion to the centre shaft by fixing on the end of the twist shaft a spur wheel gearing into a spur wheel on a horizontal shaft, which carries a bevel wheel gearing into a bevel wheel on the centre shaft. The wheel on the horizontal shaft traverses to and fro with the mule carriage, and gives the required revolution of the spindles with greater certainty than the ordinary grooved pulleys and rim bands. *Patent abandoned.*

1782. W. J. Curtis. *An improvement in the construction of screw propellers.* Dated June 16, 1862.

The patentee claims so constructing screw propellers that they will admit of being mounted in such a position on their driving shafts that the centre of gravity of the screw propeller will always be in a line drawn through the centre of the pintles of the rudder, the screw propeller being at the same time free to swing on its shaft at the option of the steersman. *Patent completed.*

1783. H. Bright. *Improved apparatus or arrangements for screening fires in stoves and grates, with the view to avoid accidents.* Dated June 16, 1862.

This screen or screening apparatus is to be made either of wire or open work, and caused to wind upon a roller attached to the top of the stove or fire-place, or to the sides thereof. Or it may be attached to the fender, to the mantel, or to the wall near the same. Or it may be made in parts, hinged or looped together, so as to fold up and be kept against the sides, the bottom, or top of the stoves, grates, or fire-places. Or it may be pushed up together like a bundle of rods, be drawn together like Venetian blinds, or expanded or contracted in any other manner, or drawn forwards, pushed back, upwards, or downwards, so long as, when not in use, it can be packed away clear of the fire, and yet, when required, can be drawn over the fire, screening or guarding the same to prevent accident. *Patent abandoned.*

1784. J. E. Holmes. *Improved machinery for digging or cultivating land.* (A communication). Dated June 17, 1862.

This invention relates to that description of machinery in which the land is operated upon by means of digging instruments, which act somewhat in the manner of spades. These instruments, which the inventor calls spades, are secured to shoulder-pieces or blocks, which support and strengthen them from behind. These blocks or shoulder pieces are fixed to wheels, which are mounted on a crank part of the axle-tree of the running-wheel or wheels whi rotate or roll over the surface of the land as the machine is drawn forward. To the peripheries of these latter are secured straight bars, which extend across the machine, and act as scrapers for the spade. As the machine progresses over the land, these spades are thrust out between the bars, and made to enter the earth, and dig or lift up a portion thereof, which, when the spades are drawn back within the peripheries of the large wheels, will be forced or scraped off by the scraper bars. Motion is communicated from the piston-rod of the engine to the crank-shaft, on which is mounted a pinion that gears into, and drives an intermediate wheel, whereby a large toothed-wheel secured to the arms of the running-wheels is driven. When it is desired to prevent the spades from working or entering the ground, the cranked part of the axle-tree is moved round part of a revolution, and the spade-wheels will then be lifted up. This movement is effected by causing a dog or trip lever to enter between the teeth of the large toothed-wheels, and be driven or carried forward thereby. This dog or trip lever is under the control of the engineer, who, by means of a lever and connecting rod, can easily throw it in or out of gear. *Patent abandoned.*

1785. S. H. Huntley, *Improvements in the construction of furnaces for effecting the more perfect combustion of fuel.* Dated June 17, 1862.

This invention consists in constructing inside the fire-box, or in the place over the fire-grate, of furnaces, air flues, or passages formed in fire-clay, or any other suitable material, and provided with perforations, holes, or slits, through which atmospheric air is caused to pass, and to impinge in small jets on to the top of the fire, by which a more perfect combustion of the fuel is effected.—*Patent completed.*

1786. A. Crestadora. *An improved mode of utilizing a certain well-known agent as a power to drive machinery, or to perform other work.* Dated June 17, 1862.

According to this invention the patentee obtains motive power from rarified air, and from aeriform fluids, by taking advantage of the two vital functions which are essential to the existence of combustion—the inhaling function and the exhaling function. As to the first, the improvement is based upon the chemical fact that the supply of a certain quantity of atmospheric air is necessary to effect and to carry on combustion; he therefore utilizes the atmospheric pressure consequent on the partial vacuum which is formed by what may be called the air-sucking property, by applying such pressure to the purpose of driving machinery, or of performing such other work as may be performed by the motive power thus obtained. As to the other vital function of fire, the exhaling action which is exerted through the chimney, he utilizes it by transferring to the chimney-shaft the apparatus and arrangements (described in the specification) applied to the pipe which leads to the ash-pit. *Patent completed.*

1787. J. Hunt. *An improvement or improvements in bronzing or colouring articles of copper or alloys of copper.* Dated June 17, 1862.

This invention consists in treating articles of copper or alloys of copper with a solution of bichromate of platinum, whereby a film or coating of metallic platinum is deposited on the article, and its surface thereby bronzed or coloured of a bright steel colour, or of a grey colour, the depth and character of the colour depending on the state of the surface of the article treated. If the article has been burnished previously to being treated with the solution of bichloride of platinum, it assumes a blue or dark steel tint, which varies with the length of time it is immersed, and the strength and temperature of the solution. The patentee prefers to use a weak solution of bichloride of platinum, and to heat it to the boiling point, but he does not limit himself to any particular temperature, as a cold solution may be employed with good effect. *Patent completed.*

1788. W. Sinnock. *Improvements in the manufacture of compound fabrics, and in the arrangement of apparatus for manufacturing same.* Dated June 17, 1862.

Provisional protection has not been allowed for this invention.

1789. A. W. Makinson. *Improvements in locomotive and stationary engines.* Dated June 17, 1862.

The object of this invention is to lessen the liability of the driving-wheels of locomotive engines, or of the paddle-wheels of steam-boats, to slip. This is effected by reducing the maximum rotative power, as it is termed, of the steam, without reducing the power of the steam to produce in the locomotive or the steam-boat progressive motion, so that an engine to which this invention is applied, when compared with an ordinary engine of the same power, will not make the same demand upon the adhesion at the rail in the case of the locomotive, or upon the resistance of the water in the case of the steam-boat, and, consequently, in the former case, the load upon the driving-wheels may be reduced, and in the latter case the area of the floats may be reduced. *Patent completed.*

1790. J. Nield and T. A. Nield. *Improvements in moulding or manufacturing pipes, columns, or other similar articles of cast-iron or other metals.* Dated June 17, 1862.

This invention relates to the moulding or manufacturing of faucet pipes, with a faucet either at the top or bottom, with or without snugs, and flange pipes, with or without margins or brackets, and also cylinders, rollers, columns, or shafts, solid or hollow, and either round, square, or of any other form. The patterns are placed half-way through a frame constructed for the purpose, which frame stands in a vertical position, and is fitted with pins to guide the moulding-box to its place; the pattern or patterns are held by hinges, or adjusted to their places by pulleys and slides, or other contrivance, so as to be drawn out by hand or machinery, the said patterns being held in their places by pins fixed for that purpose during the process of ramming. The frame may be so constructed as to admit of pipes, or articles of different diameters, being moulded, and one or more articles at the same time. The boxes are made to hold one or more pipes, or other articles, and are cylindrical, or of any other required form, but they are made in halves longitudinally, and are perforated to allow the escape of gases and steam, and have flanges at the top, bottom, and sides. In the inside of the boxes are flanges, or ledges, to keep the sand from falling out. The flanges on the sides are to fasten the half boxes together, and the flanges at the bottom are to fit on the seating plate, which plate can be made to answer for different sizes, either of socket or flange pipes. The bottom flanges are moulded in the recesses of the plate, which recesses are perforated, hoops being made to fit the seating for different sizes of pipes. The part of the frame boxes and seating which come in contact are forced to fit true to each other. The core barrel has a hoop at each end to enable the cores to be made true, the hoop at the bottom being tapered to fit the seating. This system may be applied to either dry sand or green sand moulding. *Patent completed.*

1791. A. Pringle. *Certain improvements in locks.* Dated June 17, 1862.

This invention consists in the use of six bolt checks, each check being complete in itself, by having its own self-acting spring, and if all the checks were brought into their proper position, they could not be retained so as to let the bolt pass with any instrument or instruments but its own key, a shield passing before the checks, cutting off all communication with the keyhole, thereby making it impossible to pick the lock, and in case of a key being lost or stolen, the checks can have their position changed, thereby making the lost key useless. *Patent abandoned.*

1792. W. Turner and E. T. Loseby. *Improvements in small arms and ordnance, and in sights for the same, parts of which may be used for measuring distances.* Dated June 17, 1862.

The object of the first part of this invention is to enable plain or smooth-bored guns to discharge shot, whether spherical or other shaped, with the accuracy of rifle-bored guns, and to allow of the part which spins the ball being quickly renewed at a small expense. This is accomplished by a twisted rod, or "spit," passing down the bore of the gun, which is secured at the bottom of the breech in such manner that it can be removed when required. This rod may be either square, polygonal, ratchet, or any other form suitable for causing the ball to follow the twist of the rod, and to spin on the gun being discharged. The second part of the invention relates to small arms, its object being to remove certain defects which exist in rifles as usually constructed with the wooden stock, which, extends along the barrel, and is bound to it by bands, or other fastenings. The defects of this arrangement are that, as the barrel and wood expand unequally, both with change of temperature and with moisture, the barrel becomes curved downward by heat, and upward by wet; whereby the ball is thrown out of the path indicated by the sights. The inventors overcome these defects by substituting metal for the ordinary wood support of the barrel. The object of the third part of the invention is to prevent the vibration to which rifle barrels are liable when "short stocked," on account of the barrel not having the wood to stop vibration by acting as a damper, as in the long-stocked rifles, and also diminish vibration in ordnance. This may be effected in different ways, to suit the different kinds of arms. One plan, which the inventors prefer in small arms, is to place a metal rib, or girder, under the barrel, so as to occupy the position of the wood in the ordinary long-stocked rifles. Another plan is to make the gun with two barrels, and place one above the other. A third method is to envelope the barrel in a metal casing. Whatever plan is used, either for small arms or for ordnance, the metal serving as the damper is *not* united to the barrel so as to form a part with it, but is left with the surfaces of the barrel and damper touching each other, so that they may stop vibration, the points of contact along the barrel being so selected as to destroy vibration in the most perfect manner. The fourth part of the invention consists in the construction of a telescopic sight, for ordnance and small arms, which may also be used for measuring distances. The telescope has a narrow band, extending across the cylinder, on the edge of which fine pointed teeth are cut, with deeper notches, to distinguish the fives and tens; this band is placed in the focus of the eye-piece, so that an observer can see the teeth distinctly as opaque points, and be enabled to make any parts of an object in the field of the telescope to coincide with one or more of these points. The telescope is attached to a frame, which allows it to be elevated to suit the range by a screw movement. The frame, including the telescope and other parts of the sight, may be detached from the cannon or small arm, and placed in the pocket. To aim with the sight, the telescope is adjusted to the proper elevation for the range, with the notches horizontal, and the object brought to coincide with the proper point along the scale, to allow for the effect of wind on the shot. To use the sight for measuring the distance of an object, the size of the object must be known; and the number of teeth over which it extends then gives its distance. It is preferred to place the telescopic sight at the side of the ordnance and small arms, so as not to interfere with their ordinary sights. When used for ordnance, it is made to swing so as to keep it vertical. The fifth part of the invention consists in the employment of a screw motion, for elevating the sliding bar of the ordinary back sight, in the use of a spring catch, to fasten the guard on the foresight; and of a hollow square for key, to obviate the projection of a solid square; also in the employment of a globe sight. *Patent abandoned.*

1793. S. Varley. *Improvements in reaping machines.* Dated June 17, 1862.

This invention relates, first, to the cutting instruments used, and consists in the application of a stationary cutter, which has A shaped or angular projections, forming a series of apices forward to the crop to be cut, and somewhat similar to the ordinary reciprocating cutters. The inventor disposes a double-edged lever cutting blade between each of the apices before-mentioned, and pivots it centrally in the rear of each V at the centre of each fixed cutter, and employs a screw as a fulcrum, by which the pressure can be regulated to press the lever cutters on to the stationary cutters, and cause them to cut like a pair of shears. He also uses a bearing point or fulcrum behind the fulcrum proper to form a rest or bearing point to hold up the rear part of the lever cutters, and so insure the proper effect of the regulating screw to keep the cutting edges together. The several cutting levers are jointed, and cut on both edges, while the tails or free ends are each connected by short connecting rods, which connect them with a reciprocating bar, by which a reciprocating motion is communicated to them from the motion of the machine, as usual in reaping machines. The second part of the invention relates to the means and apparatus for the delivery of the cut crop, which he effects by means of a rake or rakes, mounted on an endless chain or chains, wire ropes, or straps, moving in a vertical plane transversely to the forward motion of the machine.—*Patent abandoned.*

1794. W. Clark. *Improvements in the manufacture of buttons, and in apparatus for the same.* (A communication.) Dated June 17, 1862.

This invention relates to the manufacture of buttons of porcelain, bone, india-rubber, and all other substances capable of being moulded and stamped either in a heated or cold state, and whether in a soft paste, or dry and pulverized, or in a mass. These buttons are furnished with a bar or bridge piece contained within the button itself, and of the same material, serving to secure the button in any desired position by passing thread round the said bar. This bar may be formed with the button in various ways. *Patent completed.*

1795. G. Haseltine. *Improvements in roofs for railroad cars, and hurricane decks of vessels.* (A communication.) Dated June 17, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1796. J. Kellow and H. Short. *Improvements in the manufacture of blasting powder.* Dated June 17, 1862.

The patentees manufacture their improved powder thus:—They take nitrate of potash, chlorate of potash, and nitrate of soda (preferring crude nitrate of soda, and using the two nitrates in a state of solution), and with them they combine sawdust, tan, and sulphur. They sometimes, however, dispense with the nitrate of potash, or with the chlorate of potash, or with both the chlorate and nitrate of potash, and sometimes they use either sawdust or tan, instead of both the sawdust and tan. They sometimes manufacture this powder by what they call their "first method," according to which they combine the nitrates and the chlorate, and make into a solution, which they boil and absorb by tan or sawdust, or by both tan and sawdust, and after mixing the materials thoroughly, they add sulphur and dry the compound. The powder produced according to this "first method," is one that will explode suddenly, and is suitable for filling fissures (in blasting cliffs), and other purposes in which tamping or ramming is not required, the powder being, when so prepared, liable to explode during the tamping or ramming. The patentees recommend, when the "first method" is adopted, that the proportion of chlorate of potash should not exceed 25 parts by weight to every 100 parts by weight of the compound to be produced. To produce a strong powder, and with a view to avoid or reduce liability to explode under tamping or ramming, the following, which they call their "second method," can be adopted:—The two nitrates are made into a solution apart from the chlorate, which is made into a separate solution. The solution of nitrates is boiled, and while boiling it is combined with and absorbed by tan or sawdust, or tan and sawdust. Over this mixture they pour the solution of chlorate of potash in a boiling state, and mix well, so that the said solution may be absorbed, and they then sprinkle the compound with flowers of sulphur, and dry it. In this method the nitrates are not boiled or fermented with the chlorate, the object being to avoid danger of explosion during the ramming or tamping. They also manufacture, according to this invention, an improved powder of slow action, by what they call their "third method," in which they do not use the chlorate of potash in a state of solution or liquid, but employ it dry, and in a state of powder, using also a solution of nitrate of soda and nitrate of potash, which they absorb with tan or sawdust, or with tan and sawdust, and add sulphur. The nitrate of potash may sometimes be dispensed with. They sprinkle the chlorade of potash in a state of powder over the tan or sawdust, or tan and sawdust, after the same has been added to the boiling solution of the nitrates, and has absorbed it; and after mixing, they add sulphur, and dry the compound. In this method the chlorate not being dissolved, retains its full strength, and the powder will not be liable to explode during the tamping or ramming. *Patent completed.*

1797. J. Wheater. *Improvements in self-acting and other mules for spinning cotton or any other fibrous substances.* Dated June 18, 1862.

This invention has for its object the prevention of waste in cops spun by self-acting or other mules, and consists in systematically pasting, starching, or sizing, by machinery, the bottom of cops, by having a brush fixed in a box or cover containing paste, starch, or size, which brush, with box or cover, is driven by the friction of the spindles or otherwise along the bottoms of the cops, being conducted on wires placed at suitable distances from the spindles. *Patent abandoned.*

1798. J. H. Johnson. *Improvements in projectiles.* (A communication). Dated June 18, 1862.

This invention relates to various constructions and arrangements of projectiles for ordnance, and consists in a peculiar mode of applying a soft metal zone or belt to elongated projectiles, whereby such zone or belt is not only expanded by the explosion of the charge of the gun, so as to fit more accurately the bore of the gun, but at the same time expresses a certain amount of lubricating material contained in an annular groove or cavity in the surface of the projectile, and, consequently, lubricates the bore, and prevents the rifle grooves from "leading," *Patent completed.*

1799. J. WARREN. *Improvements in ploughs.* Dated June 18, 1862.

In order to attach the share to the body of the plough a screw bolt has, in some cases, been employed; it passes through corresponding holes in the share and body in a direction perpendicular, or nearly so, to the two surfaces it held in contact. This arrangement, however, has disadvantages; unless the share fits the body well, it is not firmly held by the bolt, which only serves for a centre for it to work upon, besides which, the nut, being vertically under the share, is in a part of the body where there is but little space, so that it is somewhat difficult to get at. Now, according to this invention, the patentee makes the bolt, which is bent at its forward end, to pass through the body in a horizontal or nearly horizontal direction, the hole in the share and that in the body being so formed as to admit of this arrangement. The screwing up of the bolt tends to draw the share on to the fore part of the body, until it finds firm bearing points; besides which, the bolt being necessarily longer than before to enable it to pass from the share through the fore sheaf or frame of the body, the nut comes to a part of the body where there is more room for it, and where, consequently, it will be more easily got at. The head of the bolt is bevelled on the face to correspond with the upper surface of the share, and the hole through the upper surface of the share is inclined or bevelled in such manner as to admit of the bent end of the bolt being received into the bevelled hole in the share. The mould board is fixed to the fore sheaf or frame of the body by means of a screw bolt, the head of which is sunk into a recess in the fore end of the mould board; a circular nut fixes the bolt in its place, such circular nut being received into a recess in the frame on the land side of the plough. A land side plate is applied, the fore end of which is bevelled off so as to enter a bevelled recess in the fore part of the frame, so as to produce a level or flush surface, and the plate is retained in position by means of a turn button or buckle. The patentee also, according to this invention, makes the beam of the plough in the form of an inverted trough of wrought-iron; this trough he makes of the required form, and with sides varying in depth in different parts, according to the strain likely to fall on the said parts. Another part of this invention is applicable to compound ploughs, arranged to work in both directions without turning, such ploughs having two shares and mould boards, arranged back to back, or turned in opposite directions. *Patent completed.*

1800. F. COLTMAN. *Improvements in apparatus for discharging coals, minerals, or other substances.* Dated June 18, 1862.

This invention has for its object the diminution of breakage in the discharge of coals, minerals, and other substances, and consists in causing them to be discharged in a direction towards the pit, instead of from it, as usual; that is to say, towards the higher part of the shoot or inclined plane, on to which they are usually discharged, instead of towards the lower part thereof. *Patent abandoned.*

1801. W. E. NEWTON. *Improvements in electrical brushes.* (A communication.) Dated June 18, 1862.

This invention consists in a novel combination with a brush made of wire of an electro-magnet, the poles of which are connected with the projecting wires of the brush, so that when the latter is passed through the hair, or over the surface of the body, a current of electricity shall be conducted to the body, and allowed to act as a remedial agent. *Patent completed.*

1802. W. CLARK. *An improved manufacture of boxes.* Dated June 19, 1862.

This invention relates to that class of boxes known as dry goods boxes, not being applicable for containing fluid matters, and these improvements consist in manufacturing such boxes of paper, card, or millboard, and combining several parts by hoops of metal, which, in addition to securing the parts together, strengthen the boxes and keep them in form. The paper stuff of the boxes may be further combined with cloth, such as is used for book covers, or it may be cheaper woven material, which imparts tenacity to the paper stuff. *Patent abandoned.*

1803. J. L. SMITH. *A universal fire alarum, with discharging apparatus.* Dated June 19, 1862.

This universal fire alarum is formed by attaching, suspending, or fastening a band, strip, line, or any form of gutta percha, india-rubber, or any other substance that is capable of expansion or breaking by the application of heat, to a weight, lever, or spring, so that, on the approach or application of heat, the band, strip, or line of gutta percha, india-rubber, or any other substance capable of expansion or breaking by the application of heat, may expand, stretch, or break, so that the extension, stretching, or breaking of a band, strip, or line, or any form of gutta percha, india-rubber, or other substance, may release or discharge an alarum, either by the immediate action or contact of a spring, weight, or lever, or at a distance by means of a line, wire, chain, tube, or any or all combined. *Patent abandoned.*

1804. G. SPEIGHT. *An improvement in the manufacture of head ornaments.* Dated June 19, 1862.

This invention has for its object a mode of manufacturing head ornaments in order to render them less heavy and less brittle than hitherto. For this purpose, the inventor takes strips or pieces of paper of the required size, and cements them, or otherwise causes them to adhere, to opposite sides of a piece of cloth, calico, or other textile or felted fabric, so as to obtain sufficient body or substance, or the paper may be cemented or caused to adhere to one side only of the fabric. He then dyes or stains the compound material so produced in such manner as to resemble tortoise shell, turtle shell, or other shell. He next embosses it with the desired device in a die and lace perforator, or heats it in such manner as to remove the raised portions and obtain open parts. He afterwards varnishes the substance to get a glossy surface, and bends it into shape by hand or otherwise. He lastly sews, or otherwise attaches it to artificial hair, ribbon, or other material intended to be worn on the head. *Patent abandoned.*

1805. A. HOWAT. *Improvements in the construction of water gauges and blow off taps for steam boilers and other purposes.* Dated June 19, 1862.

This invention consists in constructing the plugs of water gauges and blow off taps, with a longitudinal groove, or with a scraper, the edges of which, when the plug is turned partly round, scrape and loosen the sediment which may have collected in the body of the tap or in the plug. *Patent completed.*

1806. H. RUSHTON. *Improvements in plaiting machines to plait cotton, yarns, silk, or like fibrous materials.* Dated June 19, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

1807. W. STOKES, C. W. JAMES, and J. STOKES. *New or improved machinery for stocking and screwing guns and pistols.* Dated June 19, 1862.

This invention is carried out as follows:—On the bed of the machine a compound slide or saddle works, the said slide having both longitudinal and transverse motions in a horizontal plane. On the said compound slide the stock to be operated upon is fixed by an eccentric clamp, and parallel with the stock a pattern or model is fixed, the said pattern having the figure to be produced in the stock. The said compound slide is moved along the bed of the machine by a rack and pinion, the rack being on the bed of the machine, and the pinion on the lower part of the slide. The upper part of the slide is made to move transversely on the lower part by means of a rack and pinion. Over the bed of the machine, and extending from end to end of the bed, is a dovetail, in which a slide carrying the cutting tool and a fixed guide works. The guide, which consists of a pointed rod, is fixed to the said slide in a vertical position, and the cutting tool, which rotates on a vertical axis, is fixed parallel to the guide. Besides being capable of a horizontal motion in the dovetail, the cutting tool and guide are capable of rising and falling together in a vertical line. The cutting tool and guide are moved by hand, both horizontally and vertically, by means of an arm or lever. Rotary motion is communicated to the cutting tool by means of a pulley and band. The inventors employ about six of the cutting tools, guides, and pulleys on the dovetail slide, each of the said cutting tools being of a different size from the rest, and the stock is brought under one or other of the cutting tools to operate upon different parts. The slide carrying the stock and model can be moved from end to end of the bed of the machine, but the horizontal motion of the slide carrying the cutting tools is very limited. The stock to be operated upon is turned, and the barrel is fitted to it in the ordinary manner before it is operated upon by the new or improved machinery. After the stock and model have been fixed in the slide on the bed of the machine, the rotating cutting tool and guide are brought down upon them respectively, and the slide carrying the stock and model are moved about until the part of the stock being operated upon has been cut to the figure of the model. The position of the stock is changed, and different models are employed from time to time in order to operate upon all parts of the stock where portions have to be cut away. *Patent abandoned.*

1808. R. STANSFIELD and JOHN DODGEON. *Improvements in looms for weaving.* Dated June 19, 1862.

This invention consists, first, in an improved stopping motion for stopping the loom when the shuttle is not in the box. The inventors employ in each shuttle-box that description of swell which is acted upon by the top of the shuttle, but brings the end of the swell to the back of the box, so that, when the swell is held up by the shuttle, its end shall come in contact with a lever on the stop rod, and hold up the stop rod finger; but when the shuttle is not in the box, the end of the swell shall not be in contact with the lever, and thereby allow the stop rod finger to be depressed and come in contact with the frog and stop the loom. Secondly, in an improved arrangement of buffer or check strap. The inventors coil one end of the strap round a concentric or eccentric boss fixed to the slay or lathe, instead of fixing it to the end of the strap itself, by which means there is greater elasticity and prevention of wear and tear than in any other method. Thirdly, in an improved mode of stopping the loom when the weft thread breaks, or when there is no weft. The inventors place the weft fork on the opposite side to the setting on rod, and instead of placing the hammer on a stud, they fix it to a shaft or tube, having upon it a lever which is acted upon by the absence of the weft, and also at the other end another lever which operates upon the setting on rod or spring handle and liberates the brake, so as to stop the loom at the breakage or absence of the first pick of weft. *Patent abandoned.*

1809. C. CARTWRIGHT. *Improved means of stopping or retarding trains on railways* Dated June 19, 1862.

This apparatus is intended for stopping railway trains in the event of a threatened collision or accident, and consists, principally, of two strong vertical iron bars working or sliding in elongated stirrups attached in juxta position to the bottom of each railway carriage. On the upper portion of these bars are spiral springs, kept on by collared nuts with linch pins, which nuts are turned up round the rims (as also are the bottom of the stirrups), to prevent the springs from expanding and slipping off. The other or lower ends of the sliding bars are to be formed as hooks, being perforated at about eight or ten inches from the hooks to admit guiding rods adjusted at the bottom of the carriage. Under these hooks, and working upon the guiding rods, and kept up by spiral springs, having collared nuts and linch pins, is a strong iron bar (which the inventor calls the "director") working upon the guiding rods, having a strong stop joint in the middle to allow of its falling in a straight line. The bar or director, when not in use, is drawn up towards the bottom of the carriage by a chain passing over a roller or sheave fixed to the bottom of the carriage, and, running under another roller or sheave fixed on the bottom at the back of the carriage, is jointed to a sliding bar working on guides fixed to the back of the carriage, and rising a little above the roof, having a perforation to admit of a spring bolt, which is fixed on the roof, and by which bolt the whole apparatus is held up clear of the wheels. The spring bolt is attached to a connecting wire running along the roof of the carriage from back to front, and is joined by a chain to a similar wire running along the roof of the preceding carriage, which wire is also joined by a chain to the spring bolt on the top of the next carriage, and so on to the first carriage of the train, on which the wire is a little shorter, and is fixed by a flattened chain passing over a roller mounted on a lever attached to the front of the carriage, to prevent the wire from being bent by its being raised or depressed. In case of a threatened collision, or danger, or whenever the engineer wishes to stop the train suddenly, after shutting off the steam, he depresses the last-named lever, and thus withdraws all the spring bolts at once, and the sliding bars descending allow the directors to fall into a straight line, and directing or thrusting the hooks of the sliding bars between the spokes of the wheels, the latter are prevented from revolving, and the train is stopped. The spiral springs on the sliding bars and guide rods then come into action, and prevent or diminish the jerk which might otherwise be seriously felt. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Sept. 12, 1862.

2520. G. Bedson, Manchester, manager. Improvements in rolling wire and other rods or bars of metal.

Dated Nov. 14, 1862.

3070. H. Morgan, Liverpool, iron turner, and J. Parkinson, machine fitter. Improvements applicable to weighing machines, part of which may be used to measure liquids.

Dated Nov. 15, 1862.

3077. A. and H. Illingworth, Bradford, York, spinners. Improvements in washing wool and other fibres.

Dated Nov. 18, 1862.

3096. E P. Houghton, Liverpool, Lancaster, wine and spirit merchant. An improved method of applying breaks or apparatus for stopping or retarding railway carriages.

Dated Dec. 5, 1862.

3266. P. Cowan, Hammersmith-bridge Soap Works, Barnes, manufacturer. An improved method of purifying gas.

Dated Dec. 6, 1862.

3270. H. A. Bonneville, Paris. Improvements in the manufacture of stockings and socks. (A communication.)

3280. J. Joce, Colchester, surgeon. An improved composition or compositions for producing artificial sea water, or the odour or effects of sea water.

Dated Dec. 10, 1862.

3308. L. A. Lesage, 2, Rue Sainte-Appoline, Paris, merchant. An improved method of preparing jellies and jams.

Dated Dec. 15, 1862.

3350. M. Hyams, 55, Bath-street, City-road, cigar and pipe manufacturer. Improvements in the manufacture of cigars, cheroots, and cigarettes, and in the treatment of tobacco.

Dated Dec. 17, 1862.

3375. F. De Wylde, Great College-street, Camden-town. Improved means for the protection and preservation of lead surfaces exposed to the action of water, and for the protection of such surfaces from decomposition by atmospheric action. (A communication.)

3376. L. Latter, Leigh, near Tunbridge, farmer. Improvements in ploughs.

Dated Dec. 18, 1862.

3392. S. C. Lister, Manningham, York. Improvements in preparing, combing, and spinning, flax, silk, and other fibrous material.

Dated Dec. 24, 1862.

3448. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved construction of skate. (A communication.)

Dated Dec. 26, 1862.

3454. E. T. Loseby, 124, Wood-street, Cheapside, horologist. Improvements in the construction of instruments for ascertaining the pressure, and the moving force of the atmosphere.

Dated Dec. 27, 1862.

3556. W. H. Samson, Underhill, Wittersham. Improvements in certain machinery for cultivating land by steam power.

3458. J. and S. Freemantle, Gosberton, Lincoln. Improvements in apparatus for propelling vessels.

Dated Dec. 29, 1862.

3460. M. Ker, 14, Camden-street, St. Pancras. An improvement in wardrobes or other pieces of furniture or fittings, with glass silvered doors or panels used for toilet purposes.

3462. J. H. Riddell, 155, Cheapside, hot water engineer. Improvements in cast metal or other pipes or tubes for conveying gases, fluids, or vapours, and in the mode of connecting such pipes or tubes.

3466. G. Haseltine, No. 12, Southampton-buildings, Chancery-lane. Improvements in cartridges, and in the mode of charging small arms and ordnance (A communication).

3468. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in preserving organic substances from decay. (A communication).

Dated Dec. 30, 1862.

3472. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in ingot moulds employed in the casting of steel and other metals. (A communication.)

3476. W. Mould, Belmont, near Bolton, dresser. Certain improvements in machinery or apparatus for plaiting or folding and measuring fabrics.

3478. W. Richards, Birmingham. Improvements in cannon and other firearms, and in apparatus connected therewith.

Dated Dec. 31, 1862.

3488. F. Jaques, Nelson-terrace, Stoke Newington, gentleman. Improvements in cases for pipes, mouth-pieces, cigars, and other analogous articles.

3490. W. Maltby, De Crespigny-park, Camberwell, gentleman. Improved means of extinguishing fires by the use of substances not hitherto so applied.

Dated Jan. 1, 1863.

2. W. H. Brown, Sheffield, iron master and steel manufacturer. Improvements in battery plates.

6. R. Faulds, Glasgow, waggon builder. Improvements in traction engines or common road locomotives.

8. J. Jones, manager, Rhodes, Lancaster. Improvements in finishing or stiffening textile fabrics.

10. W. Robinson, Birmingham, manufacturer. An improvement or improvements in glasses for lamps used in ships, railway carriages, and for other like purposes.

INVENTION PROTECTED FOR SIX MONTHS BY THE DEPOSIT OF A COMPLETE SPECIFICATION.

Dated Dec. 31, 1862.

483. F. Applegate, Bradford-on-Avon, cloth manufacturer. Improvements in the manufacture of a kind of woollen cloth, known to the trade as deerskin.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

2392. G. Cooke. Securing or fastening doors.

2418. E. G. Fitton. Machinery for winding yarn or thread on to bobbins or spools.

2434. C. Garton. Applying heat in the manufacture and refining of sugar.

2438. W. H. Atkinson. Studs or fastenings.

2439. W. Clark. Musical instruments. (A communication.)

2440. E. Dyson. Throstle, spinning, and doubling machines.

2443. P. J. Bossard. Stoppers. (A communication.)

2447. J. Platt and W. Richardson. Burning of bricks and tiles.

2348. H. L. Emery. Ginning cotton.

2450. J. Platt and W. Richardson. Manufacture of bricks and tiles.

2451. W. Slater and W. R. Harris. Self-stripping carding engines.

2453. H. W. Hart. Argand and other burners.

2459. J. R. Johnson and J. A. Harrison. Taking photographic panoramic pictures.

2460. S. H. Huntly. Cooking apparatus.

2461. J. Snider, jun. Increasing the durability of, and for preserving cloths.

2462. S. Pudney. Manufacture of sulphuric acid.

2463. H. Hughes. Fluting or goffering machines.

2464. E. L. Duncan. Manufacture of splints.

2469. F. D. Artingstall. Balances.

2471. J. Whitehead. Looms.

2472. J. Hartshorn and W. Redgate. Manufacture of lace fabrics.

2474. G. W. Belding. Wringing machine. (A communication.)

2481. W. Hirst. Manufacture of paper or linen spool tubes.

2487. W. Rothera. Rivetting boiler plates.

2489. J. Vigouroux. An inoxydable white metal, suitable for making taps or cocks.

2493. A. Rigg, jun. Carrying and tipping coal and other minerals.

2497. G. Weeks. Constructing frames, trays, pots, or holders for flowers, plants, or shrubs.

2500. J. Hemsley. Fabric or material for scarfs, ties, handkerchiefs, and neckerchiefs.

2501. R. A. Brooman. Cultivating the soil. (A communication.)

2510. A. Whytock. Coated and uncoated sheet-iron boxes.

2512. J. B. Smith. Washing and mangling machines.

2514. J. R. Johnson and J. S. Atkinson. Printing types.

2518. A. J. Moreau. Reducing or melting pulverized metals or metallic ores.

2520. G. Bedson. Rolling wire and other rods or bars of metal.

2535. J. Webster. Manufacture of nitric and nitrous acids, and other nitrogenous compounds.

2542. W. Clark. Treatment of peat and peat tar. (A communication.)

2550. J. Simpson. Composition for coating or covering moulded or other surfaces.

2557. P. H. Whitehead. Support or stand.

2576. C. Chinnock. Construction of cork screws.

2646. J. Bucknall. Construction of horse hoes.

2650. W. and W. Carrick. Felting apparatus.

2653. J. L. Hughes. Producing ornamental patterns.

2792. G. T. H. Pattison. Embossing or finishing woven fabrics.

2793. G. T. H. Pattison. The imparting of an improved surface or appearance to fabrics woven with mixed materials.

2940. D. Spink. Propelling.

3068. W. H. Andrew. Scissors and shears.

3234. G. T. Bousfield. Apparatus for discharging guns or ordnance. (A communication.)

3257. J. Biggs, J. Johnson, T. Richardson, and T. Arnold. Manufacture of warp fabrics.

3427. G. Haseltine. Converting petroleum or coal oil into gas. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 23, 1863.

ON SAFETY LAMPS FOR MINES.

FEW still unsolved problems have more exercised man's ingenuity than that of safely illuminating the mines of bituminous coal, subject to the irruption of fire-damp. In the beginning of this century, a contrivance called the "steel mill," as also the phosphorescence of some kinds of decayed animal matter, were in use for the purpose. The steel mill consisted of a notched steel wheel revolved against a piece of flint by a boy, while the miner plied his trade by the resulting dim light.

Baron Humboldt and several other men of science, in the beginning of this century, directed their attention to the discovery of some safe means of illuminating "fiery" mines. This was before Sir Humphrey Davy, the chemist, and George Stephenson, the engineer, simultaneously, in 1815, brought out the present safety lamp. It may perhaps be said, with propriety, that Davy first *discovered* and published the scientific principle on which is based the comparative safety of the lamp, and that Stephenson first *invented* a practical lamp. It certainly was an extraordinary instance of a man of science and a man of practice meeting each other half way in an important and original invention. Be that as it may, neither "Davy" nor "Geordy" lamps entirely fulfil the conditions of safety. Numerous patents and contrivances have since been brought forward, with more or less success, to render these lamps safer, and to increase their illuminating power. Last week we illustrated one of these inventions. It is a common sense application of the hollow argand wick to the miner's lamp. The tubular wick, while it affords a better light, at the same time gives additional security, as an argand wick requires much less trimming than the flat wick. We have not seen a hollow wick employed in a miner's lamp before, and this is another instance of a very simple idea, or application, having to wait for years to be put to special ptactical use.

Induced electricity is now being tried by MM. Dumas and Benoit, the French chemists, as a safe light for mining operations. The apparatus consists of a Ruhmkorff's coil, an element of a pile, and, lastly, one of Geysler's glass tubes, the whole being so arranged as to give a light sufficient for working. The light produced does not heat the tube, and it cannot be reached by the gas. The apparatus is said to be completely isolated, and its construction is as strong as the present ordinary safety lamps. We hope to hear further about this scheme. The awful annual destruction of life in Great Britain, through fire-damp, is a disgrace to science. There does not seem to be so many lives lost in the Belgian and foreign mines generally as with us. The Government supervision in those countries, while it certainly impedes the free and unrestrained development of commercial enterprise, seems, at the same time, to give more security to the lives of the men employed.

The commonly received opinion, and the theory upon which Davy based his safety lamp, is the following:—A mixture of carburetted hydrogen (or common lighting gas) and atmospheric air is not inflammable without the *presence of flame*. It is, therefore, supposed that a red hot iron would not light the gaseous mixture. The combination of the carburretted hydrogen and atmospheric air must also undergo a high temperature to get inflamed. An explosive mixture can thus enter a lamp surrounded by a wire gauze or a perforated cylinder, and can there get lighted, but it is isolated from the mixture outside by means of the heat absorbing powers of the cylinder.

The Belgian engineer, Ponson, in his "*Traité de l'explirtation des Mines de la Nouille*," gives the following as the results of general experience with the Davy safety-lamp:—

1. A wire gauze cylinder, the meshes of which are properly proportioned as to size and number, affords, for a certain time, complete security in a mixture of fire-damp and atmospheric air. This is only in case the fire-damp is not in motion, and is not mixed with other inflammable gases.

2. The wire-gauze cylinder of a good lamp keeps the flame from spreading for only 20 minutes, sometimes even less. The wire-gauze is destroyed by the combustion of the gas inside the cylinder.

3. The inside of the chimney always shows the state of the air of the mine. It does not merely indicate the presence of the gases, but also their average proportion to the atmospheric air that is present.

If the proportion of fire-damp is small, the flame of the lamp shows the presence of fire-damp by its greater length and size. If the carburetted hydrogen should form 1-12 of the whole volume, the gauze cylinder is then filled with a light blue flame, the intensity of which increases with the quantity of the gas. If the fire-damp forms 1-6 or 1-5 of the mixture, the blue flame is then so powerful that the flame of the wick entirely disappears.

Should the atmospheric air increase, the flame of the wick reappears, but it is completely extinguished, if the fire-damp be in the proportion of 1-3 to the centre volume of air.

4. Many experiments have shown that when the lamp is placed in a *current* of pure hydrogen, an explosion is transmitted through the meshes to the outside. If, however, the current consists of ½ or of ¼ of carburetted hydrogen gas, and the remainder of pure hydrogen, the explosions are then confined to the interior of the gauze cylinder.

5. The flame of the lamp is not conducted to the outside, even if several meshes become united, or if there be holes 3 to 5 millemetres diameter (⅛ to ¼ bare) in the gauze, *if only these faults be about* 0·06 *metres to* 0·08 *metres* (2⅜ *to* 3⅛ *inches*) *above the flame of the wick.* In this case the flame appears to twist itself within the cylinder. This remarkable fact recalls to mind the theory upon which George Stephenson proceed in constructing his lamp. "Stephenson related to the Committee of the House of Commons, which sat on the subject of Accidents in Mines in 1835, that he imagined that if he could construct a lamp with a chimney at the top, so as to cause a strong current, *it would not fire at the top of the chimney*; as the 'burnt air' would ascend with such a velocity as to prevent the inflammable air of the pit from descending towards the flame; and such a lamp, he thought, might be taken into an explosive atmosphere without risk of exploding."

Should there be, however, an opening of even less than two millimetres (0·078 in.) at about the height of the wick, an explosion takes place. This is particularly the case if the stream of gas, or of the detonating mixture, be directed towards the bottom part of the cylinder. The following deductions result from experiments;—That the flame of all safety lamps has a tendency *towards* the blast of the gas, and not *upwards*, in the direction of the consumed gases in the lamp. According to this, any injuries at the top of the cylinder do not much diminish the safety of the lamp.

6. The safety of a Davy lamp is diminished by increasing the size of the gauze cylinder.

7. The wire gauze gets red hot when placed in an inflammable mixture of air; but this does not take place, and the gauze remains black, if the gases be of an explosive kind.

8. Davy soon found that a stream of explosive gas, when directed *against* the flame, could pass through it, and cause an explosion. A velocity of 300 ft. per minute was sufficient to produce an explosion.

9. The illuminating power of a Davy lamp is much less than that of a candle or an uncovered lamp. Various schemes have been tried to obviate this. Parabolic reflectors of copper have been placed in the inside of the lamp. Plano-convex lenses have also been applied to concentrate the flame on the point required to be illuminated. Most of these plans have, however, been abandoned.

It has also been proposed to place inside the wire gauze tube several thin spiral wires of platinum, in order that the miner should have light, even when the flame had been extinguished. It was supposed that a mixture of fire-damp contained a certain amount of pure hydrogen, and that the decomposition of this gas, when under the influence of the platinum, would keep the platinum at a white heat, and thus afford sufficient light to the miner. On the lamp arriving into a purer atmosphere, the heated platinum would then light the mixture of gas, and thus re-light the wick.

This plan, however, has not been successful, for obvious reasons. We have now alluded to the generally received opinion that red hot iron could not inflame fire-damp. It is probable that this opinion is liable to some modification. The combustion of a quantity of fire-damp requiring a certain temperature, the required temperature would be obtained by the presence of a large mass of hot iron, or by the fact of a current of gas being in motion at a high speed against a smaller mass of hot iron. We will quote the following out of the "Transactions of the Northern Institute of Mining Engineers" for 1853. Mr. Greenwell stated that:—

"On Friday, May 27th, 1853, he, in company with Mr Simpson, made some experiments at Townley Colliery, in order to ascertain the effect of placing red-hot iron in contact with light carburetted hydrogen gas. The gas, which may be termed 'washed gas,' as it passes through a drowned drift in the three-quarter seam of this colliery, is conveyed by means of a pipe in the shaft to the surface; it then passes through naptha into a gasometer, and thence to various burners in the shops and elsewhere. There is also a cock between the top of the shaft and the naptha vessel, whence, when opened, the gas issues in its natural form. The first experiment consisted in placing a bolt, about two inches in diameter, heated to a cherry red, in contact with the napthalized gas, in the smith's shop. The gas was immediately inflamed; in a short time, however, the iron, still at a good red heat, ceased to possess the power of exploding the gas.

"Precisely the same effects were produced when the iron was applied to the cock between the pit and the naptha vessel.

"The next experiment consisted in applying a Davy gauze, similarly heated, to the issuing gas. An immediate explosion, *inside of the gauze*, was the result, and this was repeated several times; the flame, however, did not pass through and ignite the external gas.

"From this it appears that the *mass* of hot iron applied to the gas was the occasion of its explosion, acting in the first instance by heating the gas, and in the next by igniting it when so heated; *for when iron in the condition of wire gauze, although equally hot, was applied to the current of gas, instead of the iron in the first place heating the gas to such an extent, the gas operated in cooling the iron externally after; however, the gas had passed through the gauze into its interior; it had acquired a sufficient degree of warmth to enable the opposite side of the cylinder, still red hot, to explode it.*

"If the above theory be correct, it follows that when the rapidity of the current of gas is such that the whole of the quantity passing into the gauze (supposing it to be red hot) cannot be consumed within the gauze, the surplus in a heated state must pass through, and be very liable to explode."

In the discussion that followed the reading of the above paper, Mr. Nicholas Wood, the president, recalled the fact that the gas experimented upon had passed through water, and he raised the question whether this had not given any additional inflammability to the gas.

"The gas, when tested by a heated Davy gauze, did not fire at the first wires, or in passing into the lamp; the wires, it appeared, had the effect of heating the gas as it passed through, and then, when it came to the other side of the lamp and approached the red-hot wires, it exploded. Mr. Greenwell explained that the experiments with the gauze were made with gas after it had passed through *naptha*; but in the experiments with iron there was no difference between passing the gas through naptha, and not doing so. Mr. Greenwell also stated that the gas was at the ordinary pressure, and that the explosions occurred in about a second after the gas passed through the wires, while there was the same apparent degree of heat in the whole of the experiments."

It will be seen by the above that the so-called Safety lamps gives very insufficient safety to our brave miners. The safety is dependent upon the chance chemical composition of the gases. It is further dependent upon time; a period of time limited by the destruction of the wire gauze under the influence of heat generated by the combustion of the gas within the cylinder. A current of fire-damp exceeding a certain speed, and directed against the wire gauze cylinder, will cause an immediate explosion. The size of the cylinder of the common Davy must be kept within certain limits. A very small rent in the gauze at the level of the flame will cause an explosion. The maximum space between the meshes, consistent with a limited safety appears to be less than 0·078 inches. So that a literal Damocles' sword of fire is suspended by a thread above the heads of those working in a fiery main. The "Geordy," or George Stephenson's lamp, consists of an ordinary lamp with a tall glass cover, the whole being again covered by a double casing of plate perforated with holes, through which holes the air passes to feed the combustion inside. A great security is afforded by the "Geordy," from its extinguishing itself when placed within a highly-explosive atmosphere. The wire gauze of the "Davy" gets red hot under the same circumstances.

It appears that George Stephenson was of opinion that a combination of his own glass tube with Sir Humphrey Davy's gauze cylinder would give the greatest safety, and the best light. An unprotected glass ring, however, must be a source of some danger. This has been tried, and many lamps are used made in this way. In George Stephenson's lamp, and other lamps, where the air required for combustion descends from the upper part of the lamp, great security is given from the flame getting extinguished when the lamp is placed in an inflammable atmosphere. When the fire damp gets lighted in the casing, the resulting gaseous products, not having time to escape, remain in the cylinder, and mingle with the fire-damp as it enters the casing. While this is going on, the carbonic acid gas accumulates at the bottom of the cylinder, and these united agencies render it impossible for the flame of the wick to continue in a state of combustion. It is thus out of the question for the most careless man to continue working, and a solemn warning is given him that fire-damp is present.

A miner's safety-lamp is something like a steam boiler safety-valve. The security given by a good safety-lamp in a mine is like the kind of security given by a safety-valve on a boiler. A safety-lamp shows the proportion of explosive gases in a mine, just as a safety-valve can be made to show the steam pressure in a boiler before that pressure gets to be dangerous. Neither of these two apparatus afford absolute safety, but, handled with ordinary care, under ordinary circumstances, they both prevent disastrous explosions.

The dreadful destruction of valuable life in the mines of Great Britain result from many causes. The most prominent cause, however, is fire-damp; and in many cases the irruptions of this gas are so sudden and voluminous, that scarcely any amount of ventilation can dilute the carburetted hydrogen sufficiently to prevent it igniting at a naked light. A truly safe lamp is thus an imperative necessity; and there still exists a deplorable, and even disgraceful, degree of uncertainty as to the one best mode of constructing such a lamp.

We have often heard working miners express much surprise that more had not been done to give them a better and safer light. We will venture to assert that £50 in the hands of an ingenious man of science, experimenting for this object, would do more lasting good than the same money spent in the charitable subscriptions resulting from the thrills of pity and horror at the mining disasters that continually electrify the country.

Men of science, meditating by a good coal fire, still owe an unliquidated debt to the brave hearts and hands labouring to furnish society with such absolute necessities as heat, light, and power.

H.

SHAND AND MASON'S FIRE ENGINE MANUFACTORY.

We have lately inspected with some interest the new workshops belonging to the above mechanical engineers, lately erected in the Blackfriars-road. New workshops are always more or less interesting to a mechanic, as they are necessarily always more or less up to the mark as regards new tools and new arrangements. Messrs. Shand and Mason's factory appears to be completely furnished with new machinery, chosen with very little regard for expense. We believe that about one hundred men are employed at present. This firm has been known for nearly a century in the metropolis as a purveyor of fire-engines, pumps, and other apparatus for limiting the destruction of life and property by fire—that good servant but bad master. The establishment owes its first beginning to Mr. Samuel Philips, in 1774, who also patented the chain-pump used by the royal navy. Mr. Philips was elected an honorary member of the Society of Civil Engineers, and in 1780 he was appointed engine and pump maker to the Honourable Board of Ordnance. Mr. J. Hopwood succeeded this gentleman. Mr. Hopwood's manager and late successor, Mr. W. J. Tilley, greatly extended the business, and introduced steam power into the workshops. In his turn, also, Mr. Tilley retired in favour of the present partners, Messrs. J. Shand and S. Mason. Mr. Shand held for several years the same position with Mr. Tilley, as the latter gentleman towards his predecessor, Mr. Hopwood, having been Mr. Tilley's foreman and manager for several years. Messrs. Shand and Mason have lately appeared before the public with some degree of prominence, as manufacturers of steam fire-engines. As is well known, Mr. John Braithwaite, civil engineer, was the first to make and use this powerful class of fire-extinguishing apparatus. He brought out the steam fire-engine some twenty years ago. With our national horror of novelty, it was not taken up at the time, and Mr. Braithwaite had to abandon it, after much expense and labour to himself. Not so, however, with our clever and enterprizing cousins across the Atlantic, with whom hand labour is scarce, and who have no such antipathy for novelty merely because it is new. Accordingly, Mr. Braithwaite's steam fire-engine, though rejected in England, has been for years in successful operation in that lately happy country, the United States of America. The success of the American fire-engines suggested to Messrs. Shand and Mason the feasibility of introducing them into England. In this design, the firm was unsuccessful for some time; but at last, in April, 1860, the London Fire Brigade agreed to hire on trial for twelve months a fire-engine, constructed at the expense of Messrs. Shand and Mason. This steam fire-engine was found so serviceable, that it was purchased, and several others were ordered, all of which are now in use by the London Fire Brigade. Mr. Lee's American steam fire-engine was, we believe, first tried at Messrs. Hodges's distillery in April, 1862, and it is the same engine that was exhibited in the nave of the International Exhibition.

In 1852 the largest and most powerful fire-engines in London consisted in two river engines that belonged to the London Fire-engine establishment. The largest of these two engines was worked by 120 men. In the same year steam power was substituted for hand labour on the largest of these two engines. Experience having shown the great advantages of this substitution, the directors of the London Fire-engine Establishment ordered an entirely new floating steam fire-engine of Shand and Mason. The engines drive the boat or work the pumps, as required. They are of 80-horse power, nominal, but they can work up to double that amount, throwing 2,000 gallons per minute through "8:1½ inch jets," 150 ft. high.

The workshops of this establishment appear to be as well arranged as is consistent with the limited space that can be obtained in a large town. They are disposed in several stories, and the buildings enclose an open yard where the finished fire-engines are tried. Of course, the most convenient, and, in the long run, the most economical system of constructing engineering workshops, consists in building them all on the ground floor. The saving of labour to the men in climbing up and down some 20 times a day, the superior light for the machine tools obtained by skylight windows, are among the advantages obtained by one-storey erections. The engines and the heavy reciprocating tools have all firm unshakeable foundations, the absence of which always leads to a gradual but certain deterioration of machinery. The shafting can be easily and simply arranged. A distinct *coup d'œil* is attained of all the men engaged at their work. Only a man who has himself been an operative knows the advantages to an employer in the foreman's office being placed so as to overlook the whole workshop. The entire area of a one-storied building can be covered with machine tools, as the skylight windows throw an abundance of light on any position. This arrangement, however, can only be adopted in favourable situations, where land is cheap.

In every special manufacture there ought to be special way of arranging the machinery and buildings. It may almost be said that this is of itself a branch of engineering. Of course, much will depend on the situation; and easy communication, accessibility of skilled labour, abundance of water, the future extension of the particular business, &c., would all be points to be considered. In fact, we should say, that an engineer, in arranging a manufactory for any special purpose, should design it in the same way as he would also design a machine for any special work. To the manufacturer, his factory is but a large special machine. If establishments were oftener laid out according to some proper plan, schemed before hand—with due regard to future extensions, we should not see so many senseless agglomerations of bricks and mortar as we do at present. These are not merely eye-sores to anybody with a view to order and symmetry, but they cause a perpetual loss of money. If time be money, labour is also money; and for every cwt. uselessly moved about, whether by animal or steam power, a certain amount in cash is thrown away. The materials on manufacturing should always advance forward, and should be as little as possible taken back over the old ground.

The first thing in Shand and Mason's manufactory at strikes an eye accustomed to the ordinary routine of mechanical workshops, is the great abundance of gun metal castings used in constructing the fire-engines. The greater expense of this metal is of course compensated by its superior durability, in contact with various kinds of water; and its lesser liability than cast-iron, to injury from rough usage. The erecting shop is built in the centre between the tool and fitting shops, on the ground floor and first storey. A travelling crane is erected so as to traverse above the whole, and all these shops are thereby in complete communication with each other, as the work to be removed can be traversed diagonally, as it were, from the shops on the ground floor to those above. We have seen the plan carried out in Lancashire, in a rather neater way, with slender cast-iron columns, &c. This arrangement is getting into extensive introduction, and it is well worth the notice of any one designing a comparatively small mechanical workshop.

The speciality of Messrs. Shand and Mason has taught them a proper respect for fire. Accordingly they have a large water tank on the roof, with two descending mains. Fire cocks, with proper hose, are placed on every floor, ready for immediate use. Due precautions against fire are too often neglected in mechanical workshops. We believe that those fires often begin in the pattern shop, and generally during the night. In Messrs. Stephenson's works, at Newcastle, the night watchmen were formerly, and perhaps are yet, employed during the night in sweeping up the whole shop; clearing away all the wood shavings and iron and brass chips and turnings. The night watchmen were also obliged to register their wakefulness by means of a "tell-tale clock." The result of these precautions has shown itself very strongly. There never has been a fire in the Stephenson workshops. Messrs. Hawthorn's neighbouring establishment, where these precautions have not been adopted, has been burnt down, we believe, three times. Messrs. Stephenson's establishment is of longer date than that of the Messrs. Hawthorn.

The machine tools in Shand and Mason's shop are well chosen, but there are not many novelties for us to describe. We noticed a neat little tool for turning the round wooden handles for the hand fire-engines. This was made many years ago, by Mr. Tilley, and has been transported from the former premises occupied by the firm. A tubular spindle, worked direct by a pulley, is carried in bearings on a frame. The square strips of wood, out of which the handles are to be turned, are fed with a guide in front of the tube. As the wooden strip enters into the revolving tube, it is met by a knife, or cutter, fixed to a chuck on the tube, and the wooden strip is thus turned up in its progress along the tube. This arrangement evidently embodies the main idea of the well-known Kendall and Gent apparatus for cutting brass or other tubes into lengths.

One of Mr. Cater's boilers is used for feeding the condensing engine that drives the workshop tools. A scum-pipe, on Taplin's patent, is fitted to the boiler. The water supply for the condensing-engine, &c., is procured from a well, and there are two large tanks in the yard to give the full supply required for trying any large fire-engine. The nozzle of the fire-engine being tried is adjusted in a frame, and the water is made to play up a tall mast, 155 feet high, and stayed with galvanized iron rope. This mast is partly formed of one piece of wood, 96 feet long, from Vancouver's Island, having been imported in the same cargo as the well-known large spar in Kew Gardens. Messrs. Shand and Mason make the leather hose for their fire-engines, leather fire-buckets, and also fire-escapes—in fact, all kinds of fire apparatus. The leather piping is made in lengths of about 40 ft., jointed together out of shorter lengths of 4 ft., by 3-16ths of an inch turned copper rivets. In every 10 ft. there is a leather strap for carrying the piping when full. The spirals for the suction piping are made of half-round galvanized iron wire, ⅜ in. thick.

II.

Literature.

On Photo-zincography and other Photographic Processes employed at the Ordnance Survey Office, Southampton. By Captain A. DE C. SCOTT, R.E., under the direction of Colonel Sir HENRY JAMES, R.E., F.R.S., &c. London: Longman and Co.

THE rapid development of photography during the last few years, and its successful application to art and to a variety of purposes, tend to invest a study of its progress with extraordinary interest. So wide is the range of objects to which its marvellous powers have, in a comparatively brief period of time, been extended, and so constantly are its professors applying those powers to new branches of science, that it would be simply presumptuous to prognosticate when or where photography will find the boundary line of its influence. The Patent Office literally teems with specifications of improvements effected by photographic manipulators, and, apart from that office, innumerable discoveries of a like nature are recorded. The perseverance with which the subject has been studied and experimented upon, and the brilliant success which has rewarded students and experimenters, are cheering incentives to all who are engaged in the pursuit of scientific and practical knowledge. The publication of the work under notice is therefore opportune, and the care with which it has been edited is gratifying in the extreme.

We had long been aware of the adaptation of photography to the production of the smaller series of Ordnance maps, and, in fact, last year we gave our readers a brief description of the particular process which Captain Scott has now elaborately defined. To that gentleman's exposition of photo-zincography, Colonel James has added a preface, which contains some interesting information as to its origination. The Colonel states that "when, after several years of discussion, it was finally decided to adopt four scales for the plans of the National Survey, it became evident to me that, unless I was to introduce some system by which the reduction of the plans from 1-500th to the 1-2,500th scale, and from the 1-2,500th to the scale of 6 inches to one mile, and, again, from the 6-inch to the scale of 1-inch to the mile, could be effected more rapidly than by the pentagraph, or any then known method, the progress of the work of the survey would be much too slow and too expensive to be satisfactory to the country. I therefore tried some experiments when I was in Paris, in 1855, to ascertain whether photography could not be made applicable to the purposes."

Those experiments undoubtedly formed the basis upon which was eventually raised the superstructureof photo-zincography. It was not, however, until 1859, that any really practical progress was made with the work. "I was staying," says Sir Henry, "at Ryde, in the Isle of Wight, in the winter of 1859, when a lady asked me if I knew of any means by which she could get some etchings she had made copied and printed in an inexpensive manner. After some consideration, it struck me that the chromo-carbon process could cetainly be made applicable to this purpose; and on my return the next day to Southampton I brought one of the etchings with me, and had the chromo-carbon print taken, and transferred to zinc, the same day, and this was the first photo-zincograph ever taken here or elsewhere." It is not a little singular, nevertheless, that Mr. J. W. Osborne, of the Survey Office, Melbourne, Australia, was actually engaged almost at the same period in the development of a similar process. Mr. Osborne achieved success, and thus the discovery and application of the art was "therefore made perfectly independently at the opposite extremities of the earth." We believe, however, that no tangible recognition of Mr. Osborne's services in this direction was ever made by the Government—a fact by no means creditable to it. It has been stated that Captain Scott has gone very minutely and carefully into a description of the art of photo-zincography as practised at the Ordnance Works, Southampton. It is scarcely necessary for us, perhaps, to follow here that gentleman's example, because our excellent contemporary, the *Photographic Journal*, has travelled over the same ground and elucidated every point in connection with this remarkable process.

It would be very wrong were we to omit stating that the volume, which owes so much of its value to Captain Scott's labours and explanations, is handsomely appointed, and illustrated by a number of engravings produced by photo-zincography, and photo-lithography. One of the plates expressly demonstrates the capability of these sister processes for the multiplication, with delicate minuteness, of rare printed works—it is a copy of a page of the folio Shakspeare of 1623, a work in course of reproduction at the Ordnance-office, by permission of the War Department, and at the instance of Howard Staunton, Esq., of the *Illustrated London News*. Nothing can possibly exceed the fidelity with which, in this instance, all the quaint peculiarities of typography, punctuation, and orthography, visible in the original, are reflected in the copy. An examination of this specimen alone will serve to demonstrate the exceeding value of the processes to which it owes its origin. There is no room to doubt, indeed, that photo-zincography will be made to play a still more important part than it has as yet done in the reproduction, so to speak, of ancient monuments, paintings, and engravings. In the hands of Captain Scott, especially, whose knowledge of chemistry much assists him in the praiseworthy task, there is no doubt that this art will, in time, be developed to its fullest extent. The contribution to photographic literature, which has called forth the foregoing remarks, is one for the appearance of which all lovers of the art of photography have reason to be grateful, and our only regret is that we cannot devote to it more space in our own columns.

The Engineers', Millwrights', and Machinists' Practical Assistant. By WILLIAM TEMPLETON, author of "The Operative Mechanic's Workshop Companion." Second Edition. London, Lockwood and Co., 7, Stationers' Hall-court.

FEW men have done more real service to the mechanics of England than William Templeton. For many years past his handbooks on mechanical subjects have been the constant companions—always ready to communicate actual information — of the millwright and the engineer. The plain and simple way in which those works are arranged constitutes their main feature, and their most valuable characteristic. How often have we not seen the mechanic run to his tool-chest, and appeal to his "Templeton" therein carefully preserved, for information on some rather obscure point in connection with the work he had in hand, and return in a few minutes armed for the performance of his duty.

The name of the little work, which is the most recent emanation from the pen of Mr. Templeton, and which name heads this notice, is almost sufficient to convey a perfect idea of its character. Prefixed to the "Practical Assistant" is an arithmetical guide, which will be of service to those who are on the threshold of the engine factory, or machine shop, while those who are initiated into the art and mystery of engineering, or of millwright work, will find, further on, rules and instructions on which they may at all times rely, and which compass every branch of both professions.

With the utmost confidence, therefore, we stamp this book with the approbation of the MECHANICS' MAGAZINE, and, having done so, commend it to the attention of our readers.

The Practical Mechanics' Journal Record of the Exhibition of 1862.

WE should be not only ungenerous but unjust were we to withhold our congratulations from a respected contemporary upon the realization of a conception which was in itself admirable. The well-illustrated, and, of course, somewhat bulky volume, which is the result of the combined labours of a staff of scientific gentlemen, expressly engaged for its compilation, and which bears the above title, is not only a "record," but an abiding memorial of the International Exhibition of 1862. It is necessarily encyclopædic in its character, and it embodies a mass of information on all those sections of the great display which were of most interest to the scientific and practical members of the community. To attempt an analytical review of such a work is quite out of the question. The task would be Herculean, and we should be reproducing many matters which have already been dealt with in our own pages. Those who wish to possess in a compact and systematically arranged form a record of the Exhibition, cannot do better than place this volume on their library shelves.

A very carefully prepared, and, so far as we have traced it, correct *resumé* of previous industrial exhibitions, is given at the commencement of the volume, which ends with a vision of those of the future, from the able pen of Mr. Robt. Mallet, C.E.

The Builders' and Contractors' Price-book for 1863; with an Appendix of Tables, Notes, and Memoranda. Revised by GEORGE R. BURNELL, Civil Engineer and Architect. London: Lockwood and Co., 7, Stationers'-hall-court.

This well-known and, we may add, highly appreciated volume, needs but little commendation at our hands. It has achieved for itself the position of an authority in the matters of which it treats, and so long as it is edited in the same careful manner as at present, it will certainly maintain the distinction. The appendix to the work is likely to be of great service to practical builders, contractors, and general mechanicians, and the parallel of French and English scales of measurement which it contains is singularly valuable.

Apart from the classes to whom the *Price-book* is particularly addressed, there are, in these days of scientific progress, many persons to whom it would be found a useful companion. To all such we recommend it, knowing that it will, without our recommendation, find its way into the counting-houses and offices of its own especial audience.

Every Man's Own Lawyer: a Handy Book of the Principles of Law and Equity. By a BARRISTER. London: Lockwood and Co., Stationers' Hall-court.

IT may possibly seem rather extraordinary for us to notice a work with such a title as the above, but at all events we have much satisfaction in doing so. The world has not yet reached that happy period when the terrors of the law will not be required to deter from crime or wrong-doing. Doctor Cumming may tell us, if he can, *when* that "good time" will arrive, but meanwhile coarse and even violent expedients for the repression of vice must, we fear, occasionally be resorted to. In "Every Man's Own Lawyer" we have an epitome of the laws of Great Britain. The author seems to us to have employed his powers of condensation to immense advantage, and the result is a clearly-worded and explicit manual, containing information that must be useful, at some time or other, to everybody. Of course it will not enable a man in all cases to act as a lawyer, nor supersede the solicitor's mission, but we are bold enough to say that "Every Man's Own Lawyer" will save many a six-and-eightpence to its possessor, and teach him many things which he ought to know. It is really an admirable book of its kind.

INSTITUTION OF CIVIL ENGINEERS.

ON Tuesday week a meeting of the Institution of Civil Engineers was held; John Hawkshaw, Esq., President, in the chair.

The paper read was "On Railway Telegraphs, and the Application of Electricity to the Signalling and Working of Trains," by Mr. W. H. PREECE, Assoc. Inst. C. E.

In the two papers on "Railway Accidents," by Mr. Brunlees and Captain Galton, read at the institution during the last session, it was shown that twenty seven per cent. of the accidents arising from preventable causes were due to a want of the electric telegraph. No mention was then made of accidents attributable to the presence of the telegraph, of which several instances could be cited, and which had even led to an argument being maintained against its utility; but it was contended, experience had proved that, in particular localities, such as the Victoria Station (Pimlico), the New-street Station (Birmingham), the Lickey, and other steep inclines, and long tunnels, its employment was imperative. The author did not, however, advocate the general and indiscriminate adoption of the telegraph, as a primary power, in the working of railways. It was, like many mechanical arrangements, an uncertain agent, and its chief advantage lay in its secondary or auxiliary character, in which capacity it was invaluable.

The author then proceeded to discuss the various systems that had been introduced in working long tunnels, single lines, steep inclines, draw-bridges, and other exceptional cases; alluding incidentally to the supposed superiority of working lines by an interval of space in preference to an interval of time.

The first application was that of Mr. Cooke, the original introducer of the electric telegraph into practical use for railway and commercial purposes. He suggested and established on the Eastern Counties Railway, between Norwich and Yarmouth, in 1844, what was now known as the "block" system. A line of railway was divided into sections, each having its own telegraph, which regulated the line signals, and prevented the admission of a second train upon the same length of line. For this purpose a needle instrument was employed, which showed the presence of a train upon any particular section. The author pointed out that, by making the out-door signals a representation of the indications of the needle, distant stations could be worked like distant signals; and consequently, that instead of these signals being confined to distances of about 1,000 yards, by the aid of the telegraph the distance could be increased *ad infinitum*. Most railway companies, in working long tunnels, &c., employed simply a single needle speaking instrument, which, by a momentary deflection of the needle on one side, gave "train in," and on the other, "train out." Only these two signals were used on the entry and exit of trains. This plan was condemmed as being faulty and inefficient.

Mr. Edwin Clark (M. Inst. C.E) perfected the scheme of Mr. Cooke, in the system he introduced upon the London and North-Western Railway, which was fully described. The needle instrument was employed, but its indications were made permanent by the use of continuous currents of electricity. It not only showed when the line was clear, and when there was a train on the line, but also the occurrence of an accident. This last signal was produced by rupturing wires that descended every alternate pole on the line; but this plan was thought to be dangerous. The London and North-Western Railway Company did not strictly adhere to the "block" system. They allowed two, three, and sometimes four trains to be on the same length at the same time. The "train on line" signal was only accepted as a caution, and not as a danger signal. This was a partial expedient which provided a certain amount of safety, but it was not considered sufficient under all circumstances to prevent collision. A somewhat similar, but less complete, system was adopted on the Great Northern Railway; permanent signals were not used, but carefully kept record books were maintained in which all signals were entered.

The advantages and disadvantages of speaking telegraphs in connection with signalling apparatus were considered, and it was maintained that a speaking telegraph should never form a portion of a signalling system, but be a separate and independent agent. The objections to the needle instrument, as regarded its transitory signals, and its liability to reversal, demagnetization, and injury by lighting, as well as its capability of being converted into a conversational medium, were stated to be partially avoided in Mr. Tyer's, and in Mr. Bartholomew's systems. The former was used on the North London and several other lines; the latter on the London, Brighton, and South Coast Railway. Mr. Walker's system of bells, on the

South-Eastern line, by which an indicator was dispensed with, and dependence placed solely on sound, was mentioned. The French system of M. Regnault, which did not differ essentially from Mr. Clark's, excepting that the "block" was maintained by self-acting mechanism, and not by hand— a questionable alteration—was described. The French "appareils de demande de secours" and the German bell system were deemed to be impracticable in England.

It was shown that, in all these systems, the two signals, "danger" and "safety," were not sufficiently opposite in their indications to be unmistakeable, and that this was obviated in an instrument invented by Mr. Highton, in 1854, and recently applied on the Great Western line by Mr. Spagnoletti. Written words were given in place of the deflection of a needle. Moreover, the signals in all these systems were so dissimilar to those used out of doors, that the signalmen had to master and to retain on their mind two systems, the one line signals, to regulate those of the line. The author then proceeded to describe how he had assimilated, on the London and South-Western Railway, the electric to the line signals. The instrument used by him was an exact counterpart, on a small scale, of the signals employed on the line, whether semaphore, disc, or otherwise, and it was worked in a precisely similar manner. The electric signal was simply a distant signal; and it was contended that, if a system of signalling was found sufficient to work the trains by manual power, the same system must be equally efficient when manipulated by electrical agency.

The North-Western, Mr.Tyer's, and the South-Western systems—as embracing the principle of all those in use—were compared, and their relative superiority discussed. It was argued that, while the North-Western and the South-Western systems met nearly all the conditions laid down, Mr. Tyer's system failed to do so, and, under some circumstances, had been proved to be objectionable.

Various self-acting arrangements for communicating between two trains, or a train and a station, or signals and an engine, or signals and a station, &c., were alluded to, and their impracticability shown.

The danger of using the telegraph as a medium of conversation, without carefully writing down everything sent and received, and the necessity of repeating every important message, were adverted to. The use of record books, as a check upon the telegraph, was also advised.

The method of working single lines by telegraph was then discussed. This could be done in two ways, either in a primary manner, by means of a signalling apparatus, or in a secondary manner, to give notice of the delay of trains, to hurry on one train, to stop another, to alter the authorized passing places, and to prevent the unpunctuality of one train affecting all the rest. The system in use on the London and South-Western line, and in America, in which the latter plan was employed, was described. It was argued that single lines, properly worked, would be sufficient to meet a great portion of the traffic of this country; and that large sums of money had been uselessly expended, in consequence of Parliament compelling railway companies to make double lines, where a single line would have been ample for the requirements of the district. This had been owing to the absence of a reliable signalling apparatus, and the want of confidence in, or knowledge of, the telegraph by railway managers With a well-managed speaking telegraph to regulate the trains, and a reliable signalling apparatus to regulate the signals, safety and regularity were assured; and single lines might be worked as securely and as rapidly as double lines.

The low estimation in which the telegraph was held, and the consideration it received on the part of railway officials, were regretted; and while it was admitted that where indiscriminately used, the telegraph might become a positive source of danger, and yet when carefully applied it would be found to be the greatest element of security.

It was announced that the discussion, which had been commenced, would be continued at the next meeting, Tuesday, January 20th.—At the monthly ballot the following candidates were ballotted for and duly elected:—Messrs. J. W. Brassington, J. S. Crowley, E. Gotto, and G. Wilson, as associates.

MR. DONALD McKAY ON THE FRENCH NAVY.

MR. DONALD McKAY, who is now in Paris, has just communicated to the *Commercial Bulletin* (Boston) a very interesting account of the condition and size of the French navy,. The transformation of the French navy, says Mr. McKay, to armour-clad vessels, commenced in 1855, and it will be completed in 1870, when it will consist of forty first-class iron-cased frigates, with armaments varying from 36 to 52 guns each (all rifled and breach-loading), having engines of from 900 to 1,200-horse power, and all possessing a speed exceeding nine knots per hour. The naval estimate for 1863 amounts to 143,418,920f.—nearly 30,000,000 dols. The steam navy of France at present is composed of 325 vessels of all classes, and there are 42 building. There are 6 iron-cased frigates afloat, and ten building; and there are 14 iron-plated batteries afloat, and seven building; and there are 119 sailing vessels belonging to the navy. Mr. McKay states that, of the 16 iron-cased frigates afloat and in course of construction, only two are entirely of iron; and he says:—"It is now regretted by the Government that these two were not constructed of wood, for experience has already proved, and without any contradiction, that these vessels, on account of their bottoms fouling rapidly, will not be capable of keeping up in speed with the wooden-built and coppered frigates. The 'Warrior,' of the English fleet, has lost from this cause two knots of her original speed, and it is generally conceded that these iron-built men-of-war ships will have to be taken into dock at least every three months, to clean their bottoms." Mr. McKay alludes to the speed of the pirate "Alabama" exceeding any vessel in the American navy, and she is wooden-built and copper-bottomed.

The thickness of iron casing in the French frigates afloat, as well as those on the stocks, is 4¼ in. near the load line, and 4⅜ above. "Le Gloire," "Invincible," and "Normandie," are simply timber-built vessels cased with iron. They have attained a speed of 13¼ knots per hour under steam alone, with men and armament on board. They roll easily, are tight, steer well, and are efficient fighting ships. The ten new iron-clad frigates on the stocks are similar to "La Gloire" in outline, but they will carry their battery 14 in. higher. Their dimensions are—length, 265 ft.; breadth, 56 ft.; mean draft, 25½ ft. The iron-cased frigate, "Normandie," has made the voyage across the Atlantic, and is now at Vera Cruz. She has proved to be a good sea-vessel.

Several private establishments in France are fulfilling orders for the Government. M. Arman, at Bordeaux, is building two iron-cased floating batteries. They are to be covered with 6-inch plates, and armed with 180-pounder steel guns. At Nantes, M. Gouin is building two similar batteries, but their plates are only 4¾ in. in thickness. The whole dockyard organization in France is very perfect, and arrangements were lately made at Toulon and Cherbourg whereby provisions, &c., could be put on board of a fleet in half a day for an army of 60,000 men. All the naval constructions in the French service are allowed to submit their plans to a commission, and the plan offering the most advantages, though perhaps coming from the lowest rank, is accepted. Mr. McKay recommends this excellent system to the American Government. He asserts, that, in comparison with the French and English navies, that of America is not worthy of the name; and he recommends that twelve first-class iron-cased frigates be commenced without delay. He also recommends that no iron ships be built, but wooden ships covered with plating. He says:—"Iron ships ought not to be adopted in our sea-going fleet, for the following reasons:—

"1. The fouling of their bottoms (against which no remedy has been found yet), and consequent loss of speed.

"2. The weakness of their bottoms, and consequent liability of soon breaking up whenever they touch.

"3. The impossibility to give them a good ventilation, all the artificial means having failed to produce a good ventilation, on account of the many watertight bulkheads necessarily used in their construction.

"4. Their great unhealthiness, as proved already by the few cruises made by the 'Warrior' and 'Defence.'"

SMOKE-CONSUMING APPARATUS.

JUDGING by the oft-repeated appearance in the metropolitan Police Courts of the Smoke-nuisance Inspector, Mr. Sandison, the numerous fines exacted from manufacturers and others at his instance, and the line of defence almost invariably pursued on behalf of offenders, it might well be imagined that no effective apparatus for destroying opaque smoke had yet been invented. Such a supposition, too, would be amply justified at the east end of London by the long streams of dense and foul black smoke which may be seen in the day time pouring forth from many tall and short chimney stacks, and which sometimes darken and pollute the air of the entire neighbourhood. That means of consuming smoke, both effectually and economically, do exist is, nevertheless, a fact, and those who are mulcted of fines for not observing the provisions of the Smoke Nuisance Act, have themselves alone to blame for the annoyance. At one large manufactory, in the immediate vicinity of the unclassical, but bustling region of Whitechapel, where smoke nuisances prevail, there are, to our own knowledge, in constant use, no less than seventeen furnaces, each of which completely destroys its own smoke. The manufactory in which they are is the Royal Mint, and the kind of furnace employed is that known as "Jucke's patent."

We have examined these contrivances, and can confidently say that they are of the most satisfactory nature. They are on the endless chain principle, the links of the chain, so to speak, forming the fire-bars. By means of the simplest possible driving gear, the fire-bars are made to travel slowly forward, and, after depositing clinkers, &c., under a water bridge, which passes transversely over them at the inner extremity of the furnace, they turn round a disc, and return underneath. The thickness of fire on the bars is regulated by an adjustable iron apron in front, and the fuel consists exclusively of coal screenings. Such is briefly a description of the apparatus, the patent for which has long since expired. The fireman in attendance has nothing more to do than to fill a hopper with coal-dust, for it is little else, and then the furnace becomes self-feeding. It will be readily understood, from the above remarks, that a very small quantity of fresh fuel is continually being conveyed forward from the hopper, and that the smoke caused by its introduction is instantaneously consumed by contact with the living fire within. From the fact that the fire-bars, which are of cast-iron, have time to become cool in their lower passage, they last a very long time, and retain their square edges with astonishing precision.

It seems, indeed, to us that no better apparatus for its purpose than Jucke's Smoke-consuming Furnace need be desired. It accomplishes all that is asked for by the Smoke Nuisance Act. It is simple, and yet scientific; and, as the patent right has expired, its principle may be adopted by anybody or everybody.

We have not the slightest doubt that those who wish to see the Mint furnaces in action will be gratified on application to the authorities of that establishment; and we are sure that those who do see them will thank us for directing them to the spot.—*Building News.*

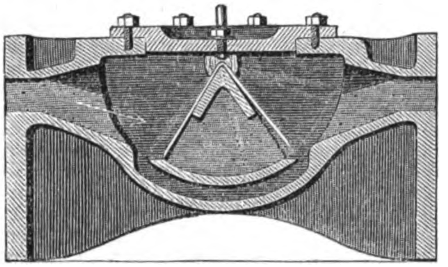
◆

The "Industry," iron steam-vessel, after repairs, has had her keel coated with patent marine cement, and will receive stores for South America.

APPOLD'S VALVE FOR REGULATING THE DISCHARGE OF WATER.

THE accompanying engraving shows a valve for regulating the discharge of water and other fluids, just patented by Mr. J. G. Appold, of Finsbury.

This invention relates to a novel arrangement of automatic apparatus, whereby the rate of discharge of water, air, or other fluids, supplied at varying pressures, may be equalized or made nearly uniform. This result is obtained by mounting in a suitably-shaped chamber, through which the water or other fluid is passed, a swing valve, the movement of which (under the excess of pressure of the water), from its vertical position, will contract the discharge passage, and thereby limit the discharge of water. The regulating chamber, in which the swing valve is mounted, is formed with a segmental bottom, and the valve, which in end view is somewhat like a hollow wedge, is made segmental at its lower edge, proportioning it so that there is a free passage of water through the chamber, both below and at the sides of the valve. The ends of the chamber are of smaller radius than the bottom, and are pierced with longitudinal vertical openings, which are parallel for a certain distance, and then have a tapering contraction upwards. It will be understood that the water or other fluid entering the chamber at an undue pressure will force the valve out of its normal position, and cause it to rise up in front of the discharge opening, the height which it rises and the consequent amount of discharge opening thereby closed depending upon the pressure put on the valve. As, however, the pressure is reduced, the valve will return towards its normal position. In applying the apparatus to hydraulic lifts, for example, it is placed between the supply valve and the cylinder. This apparatus, when the inlet and outlet passages are made alike, admits of the water, air, or other fluid, being passed through in either direction indifferently.



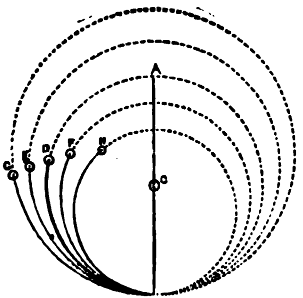
DENT'S AUXILIARY BALANCE.

THE following is a description of a new auxiliary balance invented by M. F. Dent, 33, Cockspur-street, London, and exhibited at the International Exhibition, 1862:—

By comparing a well made metallic thermometer with a mercurial one, we find that laminæ, composed of brass and steel, when properly made, bend regularly by regular changes in temperature, and that the rims of a balance, therefore, bend with regularity. As this is the case, an ordinary compensation balance possesses more compensative power in high than in low temperature; which can be proved in the following manner:—

In Fig. 1,[*] *a b* represents the arm of a balance; *c* the centre; and *b d* one of the compensation rims, standing circular with the centre in a middle temperature of 66 deg. If the end of that rim *b d*, by a change of temperature of a certain number of degrees above middle temperature, moved into *f*, it would, in the same number of degrees below middle temperature, move out to E for F B; and E B are of the same length as D B, when measured along the lines, and are parts of circles, of which one is as much larger as the other is smaller than the circumference of the balance in middle temperature. When the distance from the centre to F, D, and E is measured, it is found that a compensation weight placed on the rim, in moving from D to F, passes through a greater space, and approaches the centre of motion in a greater ratio than in moving from E to D, and, therefore, as the velocity with which a balance vibrates is in direct proportion to the distance of the weights from the centre, ordinary compensation balances must possess more compensative power in high than in low temperatures. It therefore appears, that the cause of chronometers going slower in extreme than in middle temperature is that pendulum springs, by regular increase in heat, lose strength in an increasing ratio, and in a greater proportion than the compensative power of the balance increases in the same temperature.

FIG. 1.

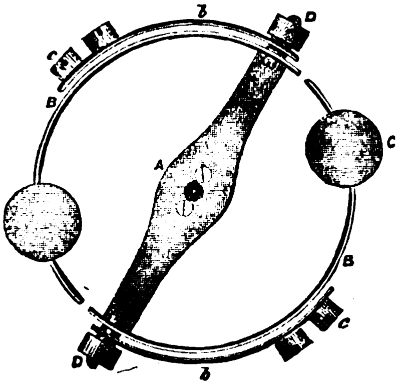


But, by again referring to the diagram, it will be seen that if the compensation rims, by the same changes of temperature, moved through a greater space—as, for example, from G to H—that that addition in the action from F to H would become larger than the addition from G to F; and, consequently, by causing the compensation weights to pass through a greater space, the compensative power of the balance is increased in high temperature.

This increase in the action of the new balance, invented by M. F. Dent, is obtained by making the compensation rims thinner. But, in adddition to this alteration, are fixed two other rims on the timing screw studs (see Fig. 2, D D). These rims have the brass inside and the steel outside, and are provided with a series of screw holes and heavy platina screws. As these rims expand in heat, and contract in cold, they not only counteract the too great effect on the compensation produced by the increased action of the primary rims, but, as they, like the primaryrims, act more when they are moving in, than when they are moving out, from their position in middle temperature, they likewise assist in making the chronometer to go faster in cold.

In Fig. 2, A is the arm of the balance; B B, the compensation rims; C C, the compensation weights; D D, the timing screws; B B, the auxiliary rims; and C C, the platina screws. These platina screws are placed nearer to the arm A, if the chronometer goes too fast in extreme temperature, and *vice versa.*

FIG. 2.



MR. WHITWORTH'S FLAT-FRONTED SHELLS.

THESE shells, that recently caused, both literally and figuratively, such a great commotion, have been made the subject of a patent by Mr. Whitworth. We extract the following from his specification, which has been lately filed, No. 1,663, dated June 2, 1862:—

Shells as heretofore constructed have not been fired in an entire condition through armour plates of any considerable thickness, such as the thick plates of iron now commonly applied to ships to protect them from injury from projectiles; they have always broken up upon impact, and when used as live shells the bursting charge has ignited prematurely. It has therefore been supposed that comparatively much thinner armour plates would suffice to exclude shells than would be required to keep out solid shot propelled with an equal charge of powder. Now, it has been found that one cause of the inefficiency of shells heretofore employed against armour plates has been that the concussion on a shell striking armour plates of any considerable thickness, and with velocity sufficient to penetrate it, generates so much heat as to explode the bursting charge in the shell, thus fracturing it before it has had time to pass through the armour plating. Another cause o the inefficiency of shells heretofore employed against armour plates has been, that the shells have been so weak that the force of blow has been sufficient to fracture them mechanically; this weakness has arisen usually from the materials of which the shells have been formed being soft or brittle, or both, and in many cases also from the form given to the shell. It is essential, in the construction of shells capable of being used efficiently against armour plates, that the fracture of the shell from the causes above mentioned should be prevented.

FIG. 2.

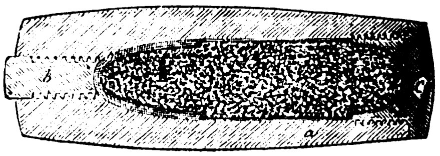


FIG. 1.

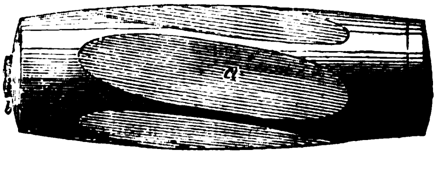

According to my invention shells are made of metal properly hardened. They are solid for a sufficient length in front of the internal cavity to give the requisite strength for penetration. The fuse usually employed for igniting the bursting charge is dispensed with, as the heat generated by the impact of the shell is sufficient to ignite the burning charge. To prevent the heat generated by impact from acting prematurely, and to regulate the time of ignition, the bursting charge is surrounded by a proper thickness of flannel, or other material which is a non-conductor of heat.

The shells are conveniently constructed of the form shown in Fig. 1 of the annexed engraving, this figure being a side view of the projectile; Fig. 2 is a longitudinal section of the same; *a*, *a*, is the body of the shell, which I make of the metal known as homogeneous iron, or of very mild lowly carbonized steel; the metal is by the makers of homogeneous iron cast into an ingot, and hammered so as to produce a bar of suitable section. Having obtained such a bar, forged approximately to the form of the shells, I cut it into lengths, each sufficient to form two shells; these lengths are then what is technically termed "converted," so as to render the exterior part more highly carbonized, and, therefore, harder than the interior, to a depth of from a quarter to half an inch. These pieces I divide, and bring to the form shown in the engraving, boring them internally, and turning and cutting them externally. This being done, I put the body of the shell into an iron box, and surround it with animal charcoal, cuttings of horn, and such like materials ordinarily employed in the process of case-hardening, and, as is usual in that process, I heat the box with the body of the shell within it to a red heat. I then withdraw it, still red hot, from the box, and having set it up on end, I cause numerous jets of cold water, by preference brine, to play both on its outer and inner surfaces, thus the shell body is rapidly cooled and rendered hard. In this state, however, it is more brittle than is desirable; this I obviate by tempering it, for which purpose I place it with its base on a block of metal, heated to dull redness, and allow it to remain there until a straw colour at the front and a blue colour at the rear indicate that it is tempered to the proper degree.

---

[*] Fig. 1 is inaccurately carried out by a mistake of the engraver. The distances between the circles, of course, ought to be the same.—ED. *M. M.*

In Figs. 1 and 2, *b*, a plug employed to close the passage through the front of the shell; the object of forming this passage is to admit of the body being more thoroughly hardened than it could be were the shell made solid in front; this plug before being screwed into its place is also hardened and tempered. *c* is another metal plug screwed into the rear end of the shell, for closing it after the charge has been introduced. The interior of the shell may be painted or thinly covered with bitumen, marine glue, or other substances, such as are used for giving a smooth internal surface to common shells. The bursting charge, which may be powder, such as is commonly used for this purpose, is then introduced, being first enclosed in a flannel bag or case, in order to prevent the heat generated by impact from being transmitted too rapidly to the bursting charge, and at the fore part of the bag, as far, say, as the points marked x, x, several thicknesses of flannel are employed, the number of thicknesses of flannel used being more or less according to the effect it is desired to produce; the longer the time which it is desired should elapse between the perforation of the armour plate and explosion of the shell, the greater will be the number of thicknesses of flannel employed. In place of flannel, other materials which transmit heat slowly may be employed, but flannel is, I believe, most convenient. By these means I am able to make use of the heat generated on the impact of the shell with the armour plating, to fire the bursting charge, after the shell has penetrated through the plating.

The shells described may also be employed for penetration like solid shot, as by removing the centre part of the forged piece, which is sometimes unsound, I am able with great certainty to make the metal of the degree of hardness required, and which is varied, as described in different parts of the body of the shell.

I have found practically that a shell such as that shown, having a maximum diameter of 7 in., and propelled by 27 lbs. of powder, will, at a range of 800 yds., penetrate with facility a 5-inch wrought-iron plate supported by a heavy backing of timber and iron skin. It will be remarked that the shells shown in the engraving are flattened in front, and for penetrating armour-plates it is very desirable that this form should be given to them. Where the conditions are such that the shell can be made to strike with its axis perpendicular, or nearly so, to the armour-plating, a shell rounded in front may be be employed, although even under these conditions it will not penetrate with the same facility as a properly formed flat-ended projectile, but where the circumstances are such (as they would be in almost every practical case), that it is impossible to secure the shell striking with its axis perpendicular, or nearly so, to the surface of the armour-plating attacked, then a shell rounded in front is deflected on striking the armour plating, and either glances off entirely, or expends its momentum with more or less efficiency, according to the inclination at which it strikes. Shells with flat ends are effective if the object aimed at be below water. Shells constructed according to my invention, may, if desired, be fitted with ordinary fuses, and it is in some cases desirable so to fit them; they will not in this manner be rendered any more useful for employment against armour plating, for which they are primarily intended, but the fuses will enable them to be fired with effect, if necessary, at objects which will not offer resistance, so as to generate sufficient heat to fire the bursting charge within it, as for example, in attacking such a ship as the "Warrior," which is only partly protected with thick armour plate, the fuse would then insure the explosion of the projectile, which might not otherwise occur were the shell not to strike the thick armour plate.

It will be observed that, in the engraving, the shell is represented smaller at the flattened end than in the middle. This construction both assists its flight, and enables it to penetrate the more readily. The front of the shell, on striking, always produces a hole somewhat larger than itself, hence the body of the shell, notwithstanding its increased diameter, will be able to follow without experiencing much resistance. The taper in front should not be such that the inclined shoulder would deflect the shell on being fired through water, nor, in being fired through a plate, should its sides have to overcome lateral resistance. Again, the degree of convexity of the front must not be such as will prevent it from taking hold or biting into the inclined surface of a plate.

A parallel form would afford the greatest capacity for a bursting charge, and also a front that would most readily bite into a surface greatly inclined. The form which I find to be the best compromise for a penetration shell is that shown.

JEUNE'S SUBSTITUTE FOR LEATHER.

MR. W. R. JEUNE, of Bow, has patented a fabric to be used in lieu of leather for various purposes, which is described as follows:—

He takes a long sheet of fabric, felt, or paper, and spreads thereon a coating of india-rubber or gutta percha, or such like solution, and when the solvent of the solution is evaporated, a thin film of rubber or gutta percha is evenly deposited on the fabric, felt, or paper; he next applies a similar coating of india-rubber or gutta percha upon a number of skins or pieces of leather, and when the solvent is evaporated by the aid of iron rolls, he unites the skins or pieces of leather and fabric, felt, or paper, by passing them through the rolls with the rubber surfaces in contact. The fabric, felt, or paper, and skins or pieces of leather now united, are rolled upon a drum and placed upon a machine, in which, whilst the sheet is kept at the required tension, a knife, running at a quick speed, splits off as much of the skin or leather as may be required. The fabric, felt, or paper is now covered with a perfect sheet of leather; the remaining portion of the skins can again be treated in the same manner as before, so that the number of times he may split the skins depends upon the thickness of them, and the purposes for which the fabric is required. The precision of the splitting, which enables him to obtain several or many slices from the same skin or piece of leather, is only attained by the aid of the fabric, felt, or paper.

The fabric, felt, or paper, having a perfect surface of leather, may be dyed and embossed in the usual way, and a fabric is thus produced at a great reduction upon the price of solid leather, and which, as it contains a film of india-rubber or gutta percha, is waterproof, and therefore fit for many purposes for which leather would not be suitable.

When a waterproof fabric is not required, other cementing materials may be employed in place of india-rubber or gutta percha. He prefers, in producing the fabric above described, to employ not whole skins, but square pieces of leather, as these will fit together, so as to cover the whole surface of the fabric, felt, or paper, without waste, or the pieces of leather employed may be of other forms.

PEEL AND SIMPSON'S HYDRAULIC PRESSES.

A SERIES of very valuable improvements have been lately patented in the above class of machinery by Messrs. George Peel, jun., and J. Simpson, both of the Soho Foundry, Manchester. The Soho Foundry is, as well known, the oldest establishment of the kind in that city. Mr. Joseph Simpson is, we believe, the gentleman who, some years ago, brought out an "eccentric" shape of steam-engine that combined in a remarkable way all the usual defects of the rotary with most of the defects of the reciprocating engine.

These improvements in the construction of hydraulic presses, consist: 1st., in making the cylinders and rams of steel instead of cast-iron, as heretofore customary; in making the columns of steel instead of wrought iron; and in making the framing for the top and bottom of the press of wrought iron or steel, either alone or combined with cast iron or other materials, instead of entirely of cast iron, the object being to unite great strength with comparative lightness.

2nd. In the arrangement of hydraulic presses, in making the rams and cylinders to work within each other in the same manner as the slides of a telescope, the largest ram works within a stationary cylinder, and the smaller ram works within the larger ram, which acts as a cylinder; in this way two or more rams of different diameters may be acted upon successively to increase the power of the press as the speed diminishes. When the smaller or smallest ram has been raised, self-acting blocks come into action to support the follower, which is then carried forward by the action of the succeeding ram.

3rd. In working hydraulic presses by forcing the water that has been used to raise the ram or rams into an air vessel, in which it accumulates under pressure, and in conveying this water again into the cylinder or cylinders of the press for the purpose of partially raising the ram or rams during the next operation, by this means the rams are rapidly raised while the pressure to be overcome is small, thus economizing power and time in working the hydraulic press. The air vessel may be charged direct by the pumps when the pumps are not required for working the press.

4th. In arranging force pumps for hydraulic presses by connecting the plungers of two or more pumps to a beam working on a fulcrum; the piston rod of a steam cylinder is connected direct to one or both ends of the beam, thereby applying the power in the most convenient manner for working any convenient number of force pumps; the pumps are or may be of different diameters, and they are provided with self-acting valves, so that as the resistance increases, the larger pumps are successively thrown out of action.

We illustrate the second and third of these improvements.

Fig. 1 is an elevation of a hydraulic press, the cylinders of which work within each other. *a* is the lower or fixed cylinder, in which works the hollow ram *b*, which forms the cylinder for the second ram b^1; to the upper end of the ram b^1 is attached the follower *g*, to which are suspended the self-acting blocks *h*, *h*, the point of suspension of these blocks being so situated that the blocks when at liberty lean towards the ram b^1; to the upper end of the hollow ram *b* is attached the plate g^1. When this press is started, the rams and cylinders fit within each other as shown in Fig. 1, and the water under pressure is admitted into the hollow ram *b*, thereby raising the ram b^1 until it assumes the position shown in dotted lines; at this time the blocks *h*, *h*, catch on the plate g^1, to retain the parts in their proper position; the water under pressure from the hollow ram *b* then enters the cylinder *a*, and acts upon the hollow ram *b*, thereby raising it into the position shown; as soon as the follower *g* has attained the required elevation, a stop valve is closed, or the pumps stopped, and the whole is retained in this position, while the bale is being lashed or corded.

More than two rams and cylinders may be made to work into each other, like the slides of a telescope, as above described, for the purpose of increasing the power of the press in proportion to the increasing diameters of the rams on which the water under pressure acts. When it is desirable to restore the parts of the press into the positions shown in Fig. 1, the blocks *h* are moved apart by hand or by suitable mechanism, until they clear the centre portion of the follower g^1; the water in the hollow ram *b*, and in the cylinder *a*, is then allowed to return into the usual receiver from which the force pumps draw their supply, or the water is collected in the air vessel or hydraulic accumulator, shown on the elevation, Fig. 2. In this view, *i* is the air-vessel, fitting upon the stand *j*, the joint between the two being formed by the cup leather j^1; the water is admitted from the cylinders of the presses, above described, or from the cylinders of any other hydraulic presses, to the vessel *i*, through the inlet pipe *k*, screwed into the valve box k^1, in which is the valve *l*; this valve is raised by the water entering the air vessel, and is closed by its own gravity, or from the pressure in the air vessel; the valve *l* is a safety valve, the pressure on which is regulated by varying the position of the weight on the lever l^1, as usual; *m* is the outlet pipe for conveying the water from the air vessel *i* to the cylinder of the press, and the valve in the outlet pipe is opened and closed by a screw and handle or other convenient means. The mode of operation is as follows:—When the apparatus is first started the vessel *i* is full of air, and the communications between the inlet pipe *k*, and the cylinder of the press being opened, as soon as the water is turned off to release the pressure on the follower of the press, it is forced into the air vessel *i*, thus compressing the air within it; the water will continue to flow into the air vessel *i*, until the air within it is compressed to the same extent as the water issuing from the cylinder of the press; the valve *l* then becomes closed, and the rest of the water from the cylinder is carried off to the usual cistern. The water under pressure in the air vessel *i* is kept in reserve until it is again required in the cylinder or cylinders of the press for the purpose of partially raising the ram or rams during the next operation. The final compression must be given by the force pumps as usual; by this means the rams are rapidly raised while the pressure to be overcome is small, and a considerable economy of time and power is effected in working the press. The air vessel may be charged with water direct from the force pumps, when the pumps are not required for working the press, and that a series of air vessels in communication with each other, may be employed.

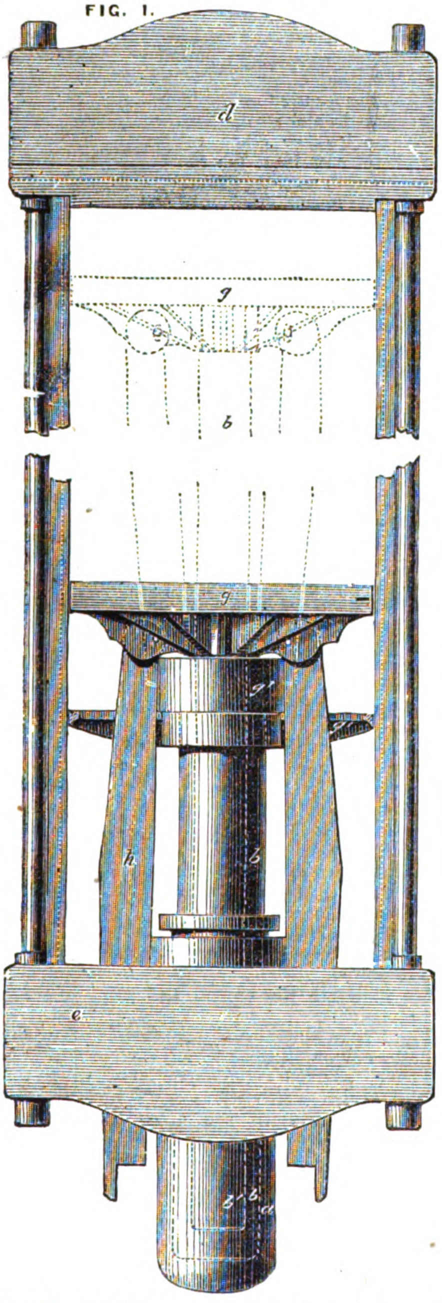

FIG. 2.

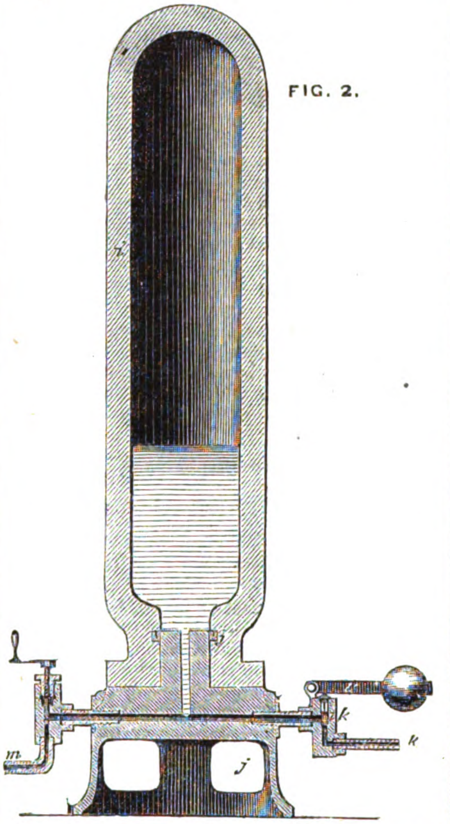

JOY'S IMPROVEMENTS IN FORGE HAMMERS.

THIS invention consists, first, in actuating hammers (hitherto driven directly by tappets, cranks, cams, or eccentrics,) by the intervention of a spring or elastic medium between such tappet, crank, cam, or eccentric, thus giving to the blow the character of elasticity; and to moderate the force of the blow, the elasticity is taken up by allowing the bar or block to work in a cylinder, or itself to be a cylinder, in which a piston is suspended, and admit air freely to such cylinder, or check it therein, thereby checking the blow due to the momentum of the hammer bar or block driven, as above described.

The second part of this invention has reference to steam hammers, and is supplemental to Mr. Joy's patent, dated the 1st of November, 1860, (No. 2,668), and consists in leaving out the valve, for the admission and exhaustion of steam, and in making the piston itself serve as a valve by allowing it to pass over and uncover a port or ports in the cylinder at proper intervals for the admission and exhaustion of steam; or reserve the action, and make the piston stationary, and allow the cylinder to move over it.

Figs. 1 and 2 are side and front elevations, with parts in section, of the first class of hammer, in which, however, india-rubber bands *e*, *e*, are used to transmit the motion of the crank or eccentric *c* to the hammer bar *a*, the cushioning of the blow being performed as before described. In both these, or any other such arrangement, the parts may be reversed, and the cylinder may be made to move while the piston is stationary.

Mr. Joy's new steam hammers are shown in Figs. 3, 4, and 5: *a* is the hammer-bar working in the cylinder *b*, which hammer-bar also serves as the valve. The steam is admitted at *c*, and the exhaust steam escapes at *d*. The upper part of the piston rod at a^1 is merely a pipe conveying steam into the body of the piston, or it may be fast to the cylinder lid and the piston slide upon it, being bored for that purpose. From this pipe the steam passes by the cross ports a^{11}, a^{11}, into cylinder by the open ports b^1, b^1, the same action taking place at the top or bottom of the cylinder accordingly as the piston is in either position. The exhaust escapes at *d* by the piston passing over that port upwards or downwards. The regulation of the speed or force of the blow is accomplished by the steam cock *h* and handle h^1. Fig. 3 is a longtitudinal section of the hammer so described; Fig. 4, a cross section vertically; Fig 5, a sectional plan at line Z Z.

Proceedings of Societies.

SCOTTISH SHIPBUILDERS' ASSOCIATION.

December 1, 1862.

JAMES RODGER, Esq., Vice-President, in the Chair.

Remarks on the Build and Equipment of Passenger Steam Vessels. By Mr. GEORGE BARBER, Shipwright Surveyor to the Board of Trade.

AFTER some introductory remarks, Mr. Barber said:—

Now, beginning with the HULL of the ship, I think that the most striking alteration, and I may say improvement, that has been made in the construction of merchant steam vessels within the last three years, is the introduction, in many of our large foreign-going steamers, of iron upper decks. They add considerably to the strength of the vessel, and a simple method has been discovered for preventing the cargo being damaged by the condensed vapour of the holds. For the safety, or, at any rate, for the comfort of those who have to work the vessels, I would prefer that where the deck is composed of ordinary smooth plates, there should be a light sheathing of wood; but it is a question whether, if, instead of doing this, it would not be better to use the plates which are rolled with checks, the checks being filled in with asphaltum or Portland cement; for I have not heard that any complaints have been made of the decks formed of this description of plate.

I believe that the IRON which is now generally used for ship-building is of a much better quality than that which was in use two or three years since. At that time it was considered or said to be almost impossible to get, for ship use, the *best* description of iron. The earnest and able articles which from time to time appeared in the various mechanical and scientific journals had, however, the effect of directing special attention to the subject. The experiments conducted by Lloyd's surveyors, and the report of those gentlemen to the committee, discovered and made notorious the fact that worthless, coarse-grained, badly integrated iron, was then much in use; and the recommendation with which the report closed, that makers of that description of iron and shipbuilders should be "warned of the discredit and mischievous results likely to fall on them through the use of such material," together with the regulation, so promptly

JOY'S STEAM HAMMERS.

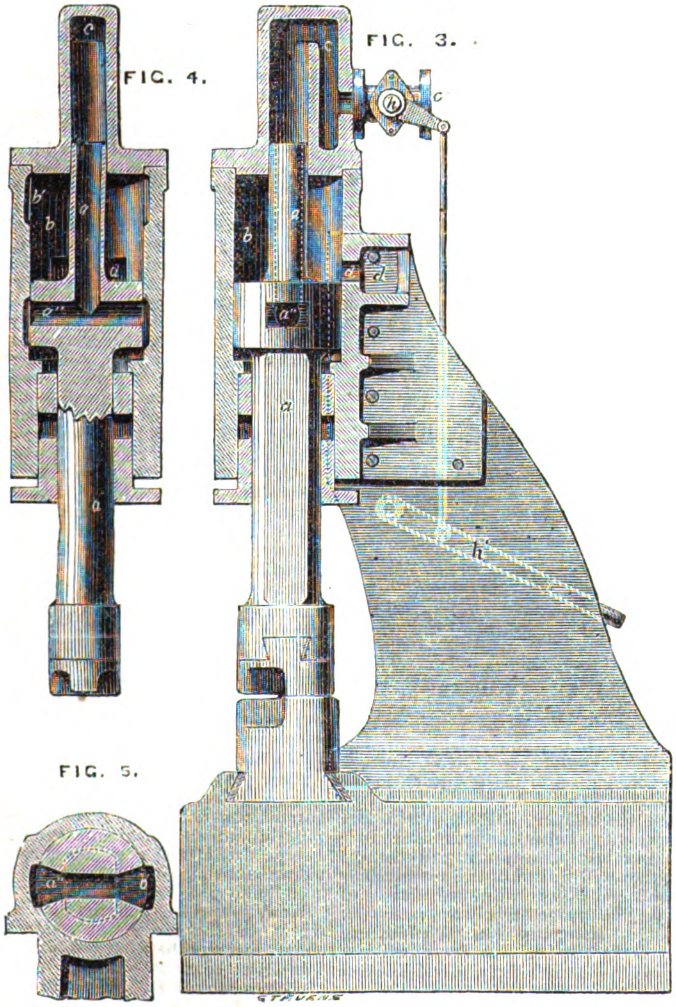

FIG. 4. FIG. 3. FIG. 5.

issued, that the maker's name should be stamped in two places on every plate, frame, and beam, used in the construction of vessels intended for classification, had the effect of arresting the progress of manufacture, for ship-building purposes at any rate, of such inferior material. At the same time Mr. Kirkaldy was conducting quietly, and with great care and patience, a series of experiments, the results obtained from which, together with the inferences deduced therefrom, have since been published, and form a most valuable book of reference. The numerous specimens of iron and steel upon which those experiments were conducted, and which it should be remembered were not manufactured specially for the purpose of experiment, but were selected promiscuously from engineers' and merchants' stores, are here beautifully arranged before us. An examination of them will, to those of us especially who have made ourselves acquainted with the tabulated results, be most interesting and instructive, and will prove, as conclusively as did the larger specimens at the late International Exhibition, that, even for ship-building purposes, iron of the very best quality can now be had from not a few of the iron manufacturers of this country.

Neither "homogenous metal" nor steel have yet been much used in ship building. It appears that corrosion takes place and progresses as rapidly upon these as upon common iron, and the advantages of comparative lightness and strength are, therefore, not alone sufficient to ensure the adoption of either of these kinds of material for the hull, although both have been found very suitable for masts and yards.

Ship builders are often blamed for not using the very best iron, but they are often blamed unjustly. It is absurd and unreasonable for an owner to bind a builder to the use of none other than the very best material, and the performance of the very best workmanship, while, at the same time, he is fully aware that the price beyond which he is not prepared to go is barely sufficient for the very worst material and the very worst description of workmanship. If owners would be a little more liberal, both as to price and to *time*, the result to themselves, to the builders, to the surveyors, and to the public, would be far more satisfactory.

You will remember that some two years ago I impressed upon you the importance of paying attention to the propér fitting of the butts in iron vessels, and I stated that I believed the practice of planing the butts, which obtained at some of the building yards at foreign ports would, before long, be universally adopted by the iron ship-builders of this country. I am glad to say, that at one at least of the building yards on the Clyde this improvement has been carried out. A short time since I was invited to examine, in the yard to which I refer, a large sailing ship which has just left the Clyde, and I was struck with the beautiful appearance of the butts; they fitted, or, to use a more expressive term, though one not so well understood on the Clyde, they *fayed* against each other most perfectly; no "bashing" of the butts and consequent punishment or destruction of the fibre of the iron had been necessary, and I was assured that the results of the introduction of the planing machine were so satisfactory, not only in the production of such excellent work, but also in the saving of time and labour, that another machine had been ordered for the same yard; and although "hand-made," butts have now reached a degree of perfection which a few years ago would have been considered wholly unnecessary, I feel persuaded that before long every builder on the Clyde will adopt this improvement, and that we shall never again see in new vessels, what I must admit is but rarely to be seen here—butts an eighth of an inch open, or caulked up with "slips."

It is also very gratifying to me to know that the suggestion that I made about the two stuffing-boxes aft has been acted upon, and I am confident that the vessels so fitted have an additional means of safety in the event of any accident happening to the stern-tube or its stuffing-box.

I have had my attention directed to the danger attending the arrangement which is sometimes carried out in ocean-going steamers, of allowing pipes connected with the machinery to pass through the ship's side in places where they cannot at all times be examined. Some pipes pass through the coal-bunkers, and can, therefore, be but seldom examined; by-and-bye, when the vessel is pitching and rolling in a heavy sea, the pipe, which perhaps has been eaten nearly through at its juncture with the ship's side, gives way, and before the defect can be remedied the coals have to be removed, while the vessel is all the time in danger of being filled. I am fully aware of the difficulties by which engineers are surrounded when arranging the pipes and cocks in a vessel; but if, in all cases such as I have described, a small recess were to be made in the bunker, just large enough for a man to get to examine the pipe, very little coal space would be lost, and an immense advantage in point of safety would be gained.

When I last addressed you, I stated that I believed you would all agree wlth me in thinking that an alteration of that section of the "Merchant Shipping Act," which referred to BULKHEADS, was absolutely necessary, and that, instead of requiring a vessel to be divided by two bulkheads into three compartments, it should require such a number of water-tight compartments, that, in the event of any one being injured, the vessel might be kept afloat by the buoyant capacity of the remainder. I presume that most, if not all, of you are by this time aware, that, instead of such an amendment having been made, the legislative interference with respect to bulkheads has been entirely withdrawn. By the "Merchant Shipping Act Amendment Act, 1862," the 300th section of the principal act is repealed, and builders and owners are now at liberty to decide for themselves the number, position, and thickness of bulkheads. In steam vessels, which will require to be surveyed for a passenger certificate, the Surveyor will not, as heretofore, exercise a supervision over the bulkheads, shaft-tunnel, &c., but he will have to satisfy himself that the vessel is sufficient — of sufficient strength and efficiently equipped — for the service for which she is intended. I mention this to you this evening because, from the questions which are being continually put to me by builders, it appears that this alteration in the act is but imperfectly understood. It seems to be thought that the news is too good to be true, though many builders and owners, who regard bulkheads as a means of safety, have assured me that all vessels built by or for them, shall be fitted with bulkheads and shaft-tunnel as efficiently as heretofore; and I trust that this will be the practice generally.

Within the last twelve months three or more sailing vessels have been built at this port of a combination of wood and iron, and one, if not two steam vessels of large size, are about to be constructed on the same principle. Being a disciple of the old wooden school, though almost a convert to iron, I very readily accepted the invitation of the builder to "take a look through" the first of these that was built, and I confess that, when I looked at the substantial teak bottom, the argument used by a master of one of the mail packets which I surveyed at Liverpool came forcibly to my recollection. The master was one of the old school, and the ship was one of the good old school —built by John Wood—with thick garboard strakes, or side keels, and filled in solid between the timbers as high as the light water-line. When I had completed my survey, the master said,—"Now, sir, you have been through this ship, and you have been through that new iron ship over yonder. You know what wood is, and you know what iron is, and I appeal to you whether I am not right when I maintain that it is against reason and common sense to suppose that what we have under our feet — seven inches of bottom plank, fifteen inches of floor timber, and five inches of ceiling caulked water-tight: twenty-seven inches of solid timber—is not better for a man to run at full speed upon the rocks with than three-quarters of an inch of iron plate?" I said, "Undoubtedly you are right, and I dare say you have a much greater feeling of security in this ship than you would have in the other; but you must remember that iron vessels are not built to run on the rocks." I cannot conceal from you that I have serious doubts respecting the efficiency of both the methods of carrying out this new principle of construction which have been adopted at this port, vastly superior as they are to the method which was first introduced; and I am disposed to believe that the theory of "iron to iron, wood to wood, all one or all the other," is correct; but at the same time I am bound to admit that every detail of construction, and every argument that could be brought againt it, appears to have had the most careful consideration; and I trust that the vessels will not only answer satisfactorily the object for which more especially they have been built, but that the expectations which the builders have formed respecting their mode of construction were realized.

One of your members whispered to me that he thought it very desirable that this association should conduct a series of experiments for the purpose of ascertaining the best preservative for iron ships' bottoms. I have been thinking over the matter, and it has struck me that if those members who have iron vessels trading to all parts of the world, and to those parts especially where fouling and corrosion of an iron bottom take place very rapidly, would give the results obtained from the use of the various compositions to which they have given a fair trial, the information would be very valuable. So many paints and varnishes and compositions come under my own observation, and I hear so many different opinions expressed upon each, that I find it very difficult to decide which is best. Parker's imperial black varnish has gained an excellent character; so has Peacock's paint and M'Innes' composition; the old-fashioned red-lead, provided it is good, sustains its reputation unsullied among its many rivals; and a coating of tallow upon red lead has been tried, as a preservative from fouling, and found to answer well. Mr. Grantham proposes to protect the bottoms of our iron men-of-war by the ordinary metal sheathing attached to a sheathing of wood, which is to be secured to the bottom by a method which he has described; and although several objections have been raised against his plan, he is deserving of great credit for having made so important a matter the object of his attention and study. Before I quit this subject, I would impress upon the owners who are present the importance of keeping the inside as well as the outside of an iron ship well coated; and not only those parts of the inside which can be easily got at, but the peaks, engine and boiler spaces, and coal-bunkers, should be carefully scraped, dried, and coated as often as possible.

(To be continued.)

Meetings for the Week.

MON.—*British Architects*, at 8 p.m.
Royal Geographical Soc., Sir R. Murchison in the chair. I. "Proposed Route to Siam, across the Isthmus of Kraw," by Capts. Fraser and Forling. II. "Visit to tho Island of Tsusinia," by L. Oliphant, Esq., F.R.G.S., at 8.30 p.m.
London Inst., "On Sculpture," by R. Westmacott, Esq., at 7 p.m.
TUES.—*Inst. Civil Engineers*, Renewed "Discussion upon Mr. Preece's Paper on Railway Telegraphs, and the Application of Electricity to the Signalling and Working of Trains," at 8 p.m.
Royal Inst., "On Animal Mechanics," by Prof. Marshall, at 7 p.m.
WED.—*Soc. of Arts*, "On the best means of establishing Electrical Communication between Great Britain and America," by T. A. Masey, Esq., at 8 p.m.

◆

ALLEGED LITERARY PIRACY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Mr. Potts having persuaded himself that he has taught Mr. Todhunter, his "Euclid," further claims to be the instructor of his publisher in the printing and get-up of the book.

I must decline the honour of having been Mr. Potts's pupil in this department, as I think Mr. Todhunter will in the other. If any one will compare the two books, they will find that the resemblance is as small as well could be between two editions of "Euclid" printed in type of nearly the same size. The diagrams, head lines, and general effect, are surely as different as can be. Mr. Potts's will not increase the glory he derives from his Exhibition medal by laying groundless claim to be the instructor of distinguished senior wranglers, or of a humble publisher.

I am, &c.,
ALEX. MACMILLAN.
Cambridge, Jan. 17, 1863.

SIR,—I have only just seen a copy of the letter written by Mr. Potts respecting myself, which was published lately in your Journal.

I wish to state distinctly that neither as student, teacher, or author, *have I ever made the slightest use of any of the works of Mr. Potts.* In my edition of "Euclid," I have given reference to the sources from which I have derived assistance in the manner of arranging the propositions in the notes and in the exercises; and I have not taken a single line, directly or indirectly, from Mr. Potts's editions, or from any edition of more recent date than his.

I need not recur to Mr. Lund's attack upon me, as I published an answer at the time.

I am, &c.,
J. TODHUNTER.
St. John's College, Cambridge,
Jan. 17, 1863.

FORGINGS FOR THE "MINATOUR."

SIR,—In your journal of the 9th inst. appears a paragraph, copied from the *Army and Navy Gazette*, describing the operations being carried on at the Millwall Iron Works.

It is there stated that the heaviest of the forgings for the "Minatour" building by this company are being manufactured at those works.

This statement is altogether incorrect, as the whole of the forgings and armour-plates for that vessel, as well as for other ships building by the Government, are made by ourselves.

Requesting you to insert this correction in your next number,
I am, &c.,
JOHN FORD, Managing Director.
The Thames Iron Works and Ship Building Company (Limited), Orchard-yard, Blackwall. E.,
Jan. 16, 1862.

GUNS AND PROJECTILES.

SIR,—It was with very great surprise that I read an article under the above title in the number for Jan. 9, of your magazine. My surprise, however, was lessened, when I came to the last passage, in which the writer says:—"We should not do justice to the ablest scientific writer on gunnery, Mr. Robert Mallet, C.E., F.R.S., if we did not acknowledge that we are indebted to his admirable essay on Artillery—exhibited at the International Exhibition, for some of the technical data above referred to; *but we hold ourselves responsible for the conclusions we have drawn from them.*" It is, therefore, evident that the article, although in prominent type, was a communication.

The MECHANICS' MAGAZINE has rendered public services to the country, by the able way in which the important questions of gunnery have been discussed in its pages. Such articles as the one to which I am now alluding, would certainly *not* have advanced the cause of truth. Passing over minor points for the present, we will remark, first of all, that the writer seems to intend that the gist of the article should lie in the following classification of the rival systems of rifling ordnance. Alluding to the five systems of: 1. Armstrong; 2. Blakely; 3. Whitworth; 4. Lancaster; 5. Lynall Thomas, the writer says:—"The five systems we will designate: 1. The narrow linear; 2. The broad deep groove; 3. The polygonal; 4. The oval bore; 5. The ribbed bore."

Pray what is Mr. Whitworth's polygonal, or rather hexagonal system of rifling, but *six* "broad deep grooves?" Describe a hexagon about a circle, and what do you get but *six* "broad deep grooves?"

4. "The oval bore."

Pray what is Mr. Lancaster's "oval bore," but *two* "broad deep grooves?" It is simply nonsense to say:—"The fourth is Mr. Lancaster's invention, which strictly is not rifling, but a modification in the cylindrical bore, which produces spiral motion without rifling!" A greater absurdity cannot be conceived than is contained in this assertion. A parallel sentence to this is the following:—"Accuracy of aim and maximum range, and velocity, irrespective of the powder charge, depend upon rifling and windage!"

5. "The ribbed bore."

Now, in a rifled gun, the shot may be called a screw, and the gun the nut. Mr. Lynall Thomas simply reverses the relative position of the thread. The writer seems to call Mr. Whitworth's system "the mechanical fit." Now *all* the *four* systems we have alluded to are "mechanical fits"—that is to say, the shots have to be prepared to fit the guns just in the same way as an engine-fitter fits a steam piston into a cylinder. In reference to the two first "systems," namely, "1. The narrow linear; 2. The deep broad groove," I should be glad to be informed as to the exact frontier line where the "narrow linear" ends, and the "deep broad groove" begins. The writer farther perpetrates the following:—"The narrow linear method, in the proper sense of the term, is *not* a system of rifling *per se.* It *is a medium for preventing windage* and *giving rotary motion to the projectile*, by covering it with a coating of soft metal, which, by compression, is forced into the narrow grooves." What is all rifling but "a medium for giving rotary motion to the projectile? How rifling can be called "a medium for preventing windage," I cannot see. A piece of hempen gasket wrapped round a shot can also be called "'a medium' (!) for preventing windage." We do not suppose, however, that the use of a piece of gasket could be called "a system of rifling?" "Rifling," however, in the brain of this writer, is a kind of universal "medium." We find him saying farther on:—

"Accuracy of aim *and velocity* are, more or less, dependent on rifling. The former, it may be said, absolutely—the latter, contingently; the powder charge here being the main cause." It is well known that rifling these matters actually *diminishes* the speed of the projectile. I wish that the writer's "*accuracy of aim*" had been greater and his "*velocity*" in jumping to a conclusion had been less in these matters.

There are several other blunders of commission and omission in this short article. I have confined myself to pointing out those which are demonstrable deviations from common sense and scientific accuracy.

It is evident that the writer is not an engineer. He must be one of those, who, forced by an adverse fate into the scientific arena, strive to hide the want of practical training and scientific knowledge, by enveloping themselves in a dust-cloud of long words.

The writer sapiently remarks:—"*So vague and unsatisfactory, however, are the notions prevalent on rifling*—so opposite to each other in principle are the systems and opinions of rival gun-makers and artillerists—that evidently the art of rifling is not yet understood, much less it is practised in accordance with scientific data, which admit of mathematical demonstration. *Nothing is true which cannot be demonstrated.*"

No better proof can be afforded of the truth of the first sentence than is contained in the article we are alluding to. In the last sentence the writer appears to assert that "*nothing is true which cannot be mathematically demonstrated.*" It is impossible to credit the writer of such trash with knowledge enough of algebra to square *(a + b)*, but does he not know that there is such a thing in the world as "physical demonstration?"

I am, &c.,
COSMOPOLITAN.

Chelsea, Jan. 13th, 1863.

[We insert this letter, though it disregards some of the amenities of journalism. The writer of the article may reply to "Cosmopolitan" should he deem it advisable.—ED. *M. M.*]

Gossip.

A leathern belt was lately manufactured at Pawtucket, R. I., for a Western woollen mill, which belt was 120 ft. (240 single) in length and 28 in. in width. It weighed 600 lbs.

Two great masses of copper recently discovered in the Mesnard district, Michigan, have excited considerable attention, as evidences of the inexhaustible and wonderfully productive nature of the Lake Superior copper region. Little of the first mass was above the surface when discovered and that little was so covered by moss and small underbrush as to hardly attract attention. Upon being uncovered, and the soil removed from around its sides, traces of Indian workings were found. Two pieces, one from each end, have been cut off the mass. Where it is cut through, the mass is pure copper, and very compact. The two pieces have been taken to the smelting works, and weighed 5¼ tons. The second mass found was still larger, measuring 40 feet in length and 4 in breadth. It weighed about 50 tons.

On Monday some interesting experiments, designed to show how a telegraphic apparatus can register simultaneously in type messages of which it is the medium, were made, in the presence of the Lord Mayor and other gentlemen, at the offices of the United Kingdom Telegraph Company, in Old Broad-street, where a machine for the purpose, as invented and patented by Professor Hughes, is now in operation, communicating with Birmingham and other large towns. The instrument was first introduced in America, and has since been brought into practical use in France, and more recently in Italy, with, it is said, complete success. It is now being tried on the lines of the United Kingdom Telegraph Company, with the view to its adoption by them. The machine is fixed to a table or platform not larger than an ordinary chessboard, and is altogether very neat and compact. The electric waves are transmitted by a revolving arm, which acts in concert with a type-wheel. On the face of the instrument are 28 keys, arranged like those of a piano, but occupying less than a third of the space. These correspond with an equal number of metal plates working upwards through slots formed all round a circular disc, on the top of which, but not in connection with it, the arm and what is called "contact-maker" revolve. The type-wheel and this arm revolve together, and when a key is depressed by the operator, a plate corresponding with the letter touched is raised and a letter is printed, while at the same instant, by a graduated movement, the paper is carried on a space ready to receive the next impression. The instrument is worked chiefly by women, and very much after the manner of a piano, but with a heavier touch. It prints at both ends of the wire simultaneously and in clear type, so that the operator sees the message which is being transmitted as it proceeds, and no copying or translation being required the chance of error it avoided. The speed secured in France and in America by highly-trained operators is said to have reached from 40 to 50 words a minute. At this rate, the instrument would print matter equal to a page of the MECHANICS' MAGAZINE, in a few minutes less than an hour, assuming there was no break in the operation, which probably would be too much to assume.

Arrangements are now being made at Shoeburyness for a complete trial of the 300-pounder muzzle-loading Armstrong gun, recently forwarded from the Royal Arsenal, and also for the official competitive trial between the Armstrong and Whitworth guns.

Last mail from India brought intelligence that the great iron floating dock, built at Sourabaya, Java, from the designs of Mr. R. W. Thomson, C.E., was successfully floated into deep water on the 23rd November. It was expected to be ready for lifting the largest ships by the end of the following month. Messrs. Randolph, Elder, and Co., of Glasgow, have just completed a similar iron floating dock for the French Government. This structure is capable of lifting out of the water the largest man-of-war in the world, not excepting the "Warrior," with all her guns and armour-plates in their places. This dock is also from the designs of Mr. Thomson.

The reconstruction of the brickwork of the arches and piers of the viaduct between the Bedford and Clapham roads on the metropolitan line (running from the Victoria Station at Pimlico to the Elephant and Castle at Newington) of the London, Chatham, and Dover Railway, which gave way some three weeks since, has been completed. On Monday morning the workmen commenced the ballasting of the road, and the operations will be continued with as little interruption as possible until completed, when the connection of the road being made, the line will be officially inspected. The works, so far as they have progressed, have been carried on under the immediate superintendence of Mr. Joseph Cubitt, C.E., the engineer in chief of the London, Chatham, and Dover Company, who, with Mr. Turner and Mr. Thomas, of the engineering staff, and Mr. J. S. Forbes, the general manager, and Mr. Bishop, the general superintendent of the line, has been in constant attendance on the spot. It is intended to reopen the line for public traffic on the 1st of next month.

The first of the second course of lectures arranged by the War Department to be delivered to the officers and men of the Royal Engineers, at the Royal Engineer Establishment, Chatham, was given on Tuesday evening by Mr. J. Anderson, on "The Mechanical Properties of Materials," in the Lecture-Theatre recently constructed. The order in which the lectures will be delivered during the season is as follows:—Jan. 22, on "The Construction and Maintenance of Telegraphic Lines," by Mr. Fleeming Jenkin; Jan. 27, "Choice and Preparation of Site for Military Buildings," by Professor Parkes, M.D.; Jan. 29, "The Construction and Maintenance of Telegraphic Lines," by Mr. Fleemin Jenkin; Feb. 3, "The Elementary Principles of Machinery," by Mr. J. Anderson; Feb. 5, "Arrangement of the Parts of Military Buildings, Sewerage," by Professor Parkes, M.D.; Feb. 10, 12, 17, and 19, "Hydraulic Engineering," by Mr. S. Roberts; Feb. 24, "Mechanical Power and its Application," by Mr. J. Anderson; Feb. 26, "Structures in Iron," by Mr. W. Pole, F.R.S.; March 3, "Steam and its Productions," by Mr. J. Anderson; March 5 and 12, "Structures in Iron," by Mr. W. Pole, F.R.S.; March 10, "The Steam Engine and its Application," by Mr. J. Anderson; March 17, "Iron and Steel Manufacture," by Mr. Anderson; March 19, 26, and April 2, "Pumping and Locomotive Engines," by Mr. W. Pole, F.R.S.; March 24, "Forging and Tempering," by Mr. J. Anderson; March 31, "The Art of Founding," by Mr. J. Anderson," April 7, "Tools and Machinery for Working Wood and Metal," by Mr. J. Anderson. A lecture on the solution of mechanical problems by geometrical construction, based on a work presented to the Royal Engineer Establishment by the Rev. Canon Moseley, is in course of preparation by Lieut. Fraser, Royal Engineers.

We are informed that Mr. Jas. Bruce has recently discovered a remedy for poisoning by strychnine and by mushrooms. It consists in making the patient eat large quantities of refined sugar, and in desperate cases opening a vein and injecting sugared water. Its effects are to oxygenate the blood and restore the circulation. He recommends its application to all venomous bites, and considers that it may be tried, with much advantage, in "lockjaw and accidents from chloroform." *Le sucre c'est le veritable ami des nerfs.* The effects of most poisons on the circulation are accurately determined microscopically in experiments with frogs, bees, flies, grasshoppers, ladybirds, snails, &c.; the pulsation of the heart being easily perceived.

The great iron floating dock built at Sourabaya, Java, from the designs of Mr. R. W. Thompson, C.E., was successfully floated into deep water on the 23rd of November last. The difficulties of launching such an immense structure were evaded by building it in a kind of dam made on the sea-shore. When the iron dock was completed the sea wall of the dam was broken down, and the sea rushing in lifted the dock from blocks on which it had been built. It was then towed out into deep water. It was intended to commence docking ships for repairs by the end of December last.

M. Revial has instituted a series of experiments at the Hôpital Lariboisière, Paris, and has shown the existence of a large amount of organic matter floating in the atmosphere. The dust of a ward was collected, and found to contain 36 per cent. of organic matter, chiefly in the form of epithelial cells. In the air of rooms containing the sufferers from contagious inflammation of the eyeball, small corpuscles were detected analogous to those of the virus thrown off from an inflamed eye. It is probable that infection, therefore, is mechanically conveyed from eye to eye by means of the air.

OIL OF ASPHALTUM FOR THE PRESERVATION OF BOILERS.—M. Dollfus reports to the *Societe Industrielle* of Mulhouse his success in using the heavy oil extracted by M. Lebel from the asphaltum and bitumen, at Pechelbronn. He says that it is perfectly successful and very economical as an unguent for heavy machinery. He applied it to the inner surface of his boilers and heaters by warming them so as to make the oil more fluid, and then applying it in a thin coat by means of a common broom. The results were very satisfactory; the calcareous crusts were gradually detached and the metal everywhere exposed. "I continue to use the oil whenever I clean a boiler, and I judge that the expense, which is about 10 kilos. (20lb.) for a boiler of 45-horse power, is largely compensated by the economy of fuel in consequence of the metal being clean: repairs are also much less frequent, as the boilers do not burn out so freely."—*Bulletin de la Societe Industrielle de Mulhouse.*

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 1837, 1839, 1849, 1852.
Boilers and Furnaces, 1820, 1859.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1814, 1838, 1856.
Ships and Boats, including their fittings, 1810, 1844.
Cultivation of the Soil, including agricultural implements and machines, 1845, 1862.
Food and Beverages, including apparatus for preparing food for men and animals, 1811.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1812, 1816, 1830, 1833, 1836, 1840, 1841, 1847, 1850, 1860, 1861.
Buildings and Building Materials, 1813, 1835, 1846.
Lighting, Heating, and Ventilating, 1815, 1853, 1863, 1865.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1817, 1824, 1842, 1848, 1855, 1858, 1864.
Metals, including apparatus for their mnufacture—*none.*
Chemistry and Photography—*none.*
Electrical Apparatus—*none.*
Warfare, 1829.
Letter-Press Printing—*none.*
Miscellaneous, 1818, 1819, 1821, 1822, 1823, 1825, 1826, 1827, 1831, 1832, 1834, 1843, 1851, 1854, 1857, 1866, 1867.

1810. M. Wigzell. *Improvements in the forms of bolts, and other fastenings, for ship building and other purposes.* Dated June 19, 1862.

This consists in the construction of a circular formed bolt, nail, spike, or pin, having one or more worms, ribs, or projections of such a form, and so placed in a spiral direction around its surface, as to cause the bolt, nail, spike, or pin to revolve whilst being driven into timber after a hole has been made the size of its solid or hollow circular centre. The bolt, nail, spike, or pin is driven home by a direct blow from a hammer, and will hold into the timber, or other substance into which it may be driven, with greater tenacity than the plain circular bolts now in use. *Patent completed.*

1811. E. J. Davis. *Improvements in treating and preparing food for horses and other animals.* Dated June 19, 1862.

For the purposes of this invention, hay, clover, and straw, either cut or uncut, and whether separate or mixed, also oats and other grain, either whole, bruised, or ground, are subjected to the action of free steam, the dried vegetable substances above-named being spread on reticulated trays, or other surfaces, so that the steam may pass freely amongst, and act on, every part of the same. Or in place of steam boiling water may in some cases be used; free steam is, however, preferred. *Patent completed.*

1812. J. B. Wood. *Improvements in the manufacture of driving straps or bands, the backs of wire cards and coptubes.* Dated June 19, 1862.

Here, for the manufacture of driving straps, &c., the patentee takes buffalo, or other untanned hides, cuts them into strips or shreds, and subjects the same to the action of certain acids. He next passes the strips or shreds of hide through fluted rollers, and subsequently through plain rollers, whereby the cuttings are converted into pulp. The pulp (with or without the admixture of cotton, flax, hair, &c.) is then passed between wooden or iron rollers, adjusted so as to produce any width or thickness of sheet that may be required. *Patent completed.*

1813. W. Thompson. *Improvements in machinery for making bricks, tiles, and other articles.* Dated June 19, 1862.

Here a pug mill is mounted in the centre of a base plate, and provision is made for the delivery of two streams of clay or brick earth through two openings at the opposite sides of the pug mill. The two streams of clay are received on two sets of rollers, and by them supported to two pairs of pressing rollers, from between each pair of which the clay or brick earth is forced through a suitable die in front of the rollers, and the stream of clay or brick earth thus moulded is cut by a suitable cutting wire or wires, as is well understood. Motion is transmitted from a steam engine or other power to the axis of the pug mill, and to the axes of the two pairs of pressing rollers in the following manner:—On the driving shaft which turns in suitable bearings under the bed plate is fixed a drum or pulley to receive the driving band of the steam engine or other power. On the other end of the driving shaft is fixed a pinion, which gears into and drives a cog wheel on another shaft, which is parallel to the driving shaft, and passes under the centre of the bottom of the pug mill. The pug mill shaft or axis passes through the bottom of the pug mill, and has fixed on it a bevelled toothed wheel, which gears into, and is driven by, a bevelled pinion placed on the shaft which is below the bottom of the pug mill; and on the same shaft are two chain wheels which give motion to two endless chains, one of which gives motion to a chain wheel fixed on the axis of the upper pressing roller of one pair, and the other endless chain gives motion to a chain wheel fixed on the axis of the lower pressing roller of the other pair, by which means, and by the axes of the pressing rollers of each pair being geared together, the two pairs of pressing rollers are caused to turn in the proper direction for receiving the streams of clay or brick earth, and forcing the same through the respective dies. *Patent abandoned.*

1814. W. Jeffries. *A new or improved rail for railways, and a new or improved chair or sleeper for the said rail.* Dated June 20, 1862.

This rail consists of a bar of wrought iron or steel, the upper part of which resembles the upper part of an ordinary rail, and the lower part consists of a shank or bar, the sides of which are parallel. The rail in cross section has a figure somewhat resembling the letter T, excepting that the top or upper part is thick and rounded like the head of an ordinary rail. The new chair or sleeper to be used with this rail is made as follows:—The chair or sleeper is made of rolled or cast-iron, and consists of two upright parallel plates or bars upon a base, the lower part of the before described rail fitting in the space between the two parallel plates. Cross bolts, pins, or cotters pass through the chair or sleeper rail and secure the rail in its place. Iron of the form described may be used in short lengths separated from each other after the manner of chairs, or in long continuous lengths, so as to constitute sleepers. *Patent abandoned.*

1815. J. A. Dupuch. *Improvements in cocks for regulating the supply of gas.* Dated June 20, 1862.

This relates to cocks for regulating the supply of gas from the street mains to the meter or burners, which improved cocks offer, to those hitherto made use of, the following advantages:—1, The cock's plug cannot be withdrawn from the barrel without the communication between the entrance and the exit openings for the gas being intercepted. 2, The plug cannot leave the barrel by the trepidations occasioned by heavy carriages passing through the street. 3. The plug always fits exactly into the barrel. 4. The cock is provided with arrangement for preventing, if required, the gas from passing through the cock. 5, This latter may be easily cleaned from the street. *Patent abandoned.*

1816. J. B. T. Detuncq. *Improved apparatus or machinery for treating flax or hemp.* Dated June 20, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1817. W. E. Gedge. *Improvements in the manufacture of candlesticks, and in machinery or apparatus used in such manufacture.* (A communication.) Dated June 20, 1862.

This consists in a method (the details of which we cannot quote here) of manufacturing candlesticks of sheet zinc instead of casting them as hitherto. *Patent abandoned.*

1818. J. Bedford. *A new or improved plane iron, cut iron, or double iron, and especially for the method of manufacturing plane irons and other tools by punching, flying, or stamping by dies.* (A communication.) Dated June 20, 1862.

The first part of this invention relates to a method of applying the cutting-iron so that it may be entirely used up. For this purpose, instead of fixing the steel cutter to the iron, the patentee secures it to the latter by a screw, and so renders it completely independent of the iron. This screw runs in a slot to allow of the cutter being shifted as it wears away, and to fix it in any desired position. The cutter, when fitted to the iron as above named, is furnished with a guard-plate above the cutter, and fitted so as to slide backwards and forwards with it when adjusting the latter. Thus it will be seen that the steel cutter fitted to the iron, as described, may be completely worn out, and another one substituted, without the plane being injured. The second part consists in the manufacture of the parts above described by cutting, punching, and shaping them in a lever or other press, either in a heated or cold state, so as to produce them readily in a polished state. The holes and slots in the plane irons and cutters are also made at the same time in one single operation. *Patent completed.*

1819. W. Malins. *An improved protective covering for agricultural or other similar purposes.* Dated June 20, 1862.

This consists in the use of sheets of plane or corrugated zinc, or galvanized zinc, or galvanized iron, in lieu of thatch or canvas as at present, the said metallic covering being formed, and firmly held together, by bolts and screws, through the medium of an adjustable framing. *Patent abandoned.*

1820. D. Adamson and Leigh. *Improvements in the construction of steam boilers, and in apparatus connected therewith, part of which is applicable to ship building.* Dated June 20, 1862.

This consists, 1, In drilling holes in the curved plates, forming part of steam boilers, by any convenient number of radiating drills acting simultaneously. 2, In combinations and arrangements of machinery for drilling several holes simultaneously through boiler plates. 3, In rolling flanges on the edge or edges of plates used in the construction of steam boilers, and for ship building, which flanges are secured together by rivets or welding. 4, In applying a system of perforated pipes to steam boilers for distributing the feed water, and in connecting the said pipes to a blow-off cock, for removing the sediment. *Patent completed.*

1821. B. M. Mody. *Improvements in varnish or polish.* Dated June 20, 1862.

This relates to the manufacture of varnish or polish, so that it can be applied by a camel's hair brush, either as a varnish to any smoothed surfaced wood, or, as a reviver to old French polished wood and furniture. The ingredients used the inventor proposes to mix in the following proportions:—Methylated spirit, 1 gallon; shellac, 1½ lbs.; gum benzoin, 1½ lbs.; dragon's blood, 6 drachms; or when a clear varnish is required the dragon's blood may be omitted. The ingredients when mixed are to be subjected to a gentle heat until thoroughly incorporated, and the mixture is then to be filtered in the ordinary way. *Patent abandoned.*

1822. J. W. Taylor. *Improvements in valves, and in means for regulating and indicating the flow and pressure of fluids.* Dated June 20, 1862.

These improvements in valves consist in forming the plugs thereof of india rubber, such plugs being secured by screw nuts or other means between flanges or washers to the spindle. For indicating the pressure of liquid, the patentee applies a small ram or piston in a cylinder, the lower end of which ram is pressed on by the fluid, whilst the upper end acts by links or connecting rods upon weighted levers, to raise the weight thereof as the pressure increases, and at the same time an axis with joints is set in motion to indicate the pressure exerted. The improvements relate, also, to means of regulating the flow of water obtained by condensation. For this purpose, he applies to a chamber used as a receiver of such water, an inlet passage with a valve (capable of closing the same), to which is applied a float adapted to open such valve with the rise of the water in such chamber, and admit of the escape of such water, whilst at other times the tendency is for the valve to be closed. *Patent completed.*

1823. D. Middleton. *Improvements in cranes for lifting weights into and out of carts, and for other purposes.* Dated June 20, 1862.

This invention was described and illustrated at page 34 of the last volume of this journal. *Patent abandoned.*

1824. C. Osman. *Improvements in the manufacture of elastic or yielding surfaces for sitting, lying, or reclining upon, part of which improvemenis are applicable to other purposes.* Dated June 20, 1862.

This consists, 1, in manufacturing elastic or yielding surfaces of vulcanized india rubber, made up and arranged in hollow or cellular forms, or so as to present the edges or ends of the india rubber towards the surface of the cushion, mattress, seat, or other surface, to which it is intended to give elasticity. 2, In forming elastic or yielding surfaces for sitting, lying, or reclining upon, from sheets, strips, or lengths of vulcanized india rubber, made up into twisted, spiral, corrugated, or undulating forms, arranged side by side, and secured in position so as to form the same into surfaces suitable for seats, cushions, &c. 3, In forming elastic or yielding surfaces for sitting, lying, or reclining upon, by connecting the upper or lower ends, or both, of a series of lever arms by strips or bands of vulcanized india rubber; or such lever arms may be connected together or retained in position by helical or other springs, so as to yield or give way when pressure is applied to the surfaces which they are arranged to support. 4, In forming or manufacturing corrugated or channelled surfaces of vulcanized india rubber, suitable for being applied to the construction of seats, cushions, or mattresses, for sitting or lying upon, such corrugated surfaces of india rubber being applicable for covering floors or walls, or for being applied to the soles of boots, shoes, or clogs. *Patent abandoned.*

1825. A. Warner. *Improvements in the manufacture of pigments or paints from certain refuse materials.* Dated June 20, 1862.

This invention has for its object the application of the refuse or slag obtained from puddling and re-heating or other furnaces used in the manufacture of pigments or paints. For this purpose the patentee takes the refuse or slag above referred to, and reduces the same to a fine powder by any of the well-known mechanical operations for grinding or pulverizing similar materials or other hard substances. The ground or pulverized materials are then to be washed or otherwise treated, and combined with oil or other materials, and used as pigments or paints for various purposes, as is well understood in the manufacture of pigments or paints from other oxides of iron or other metals. For the purpose of producing the slag or cinder to a fine or impalpable powder, the patentee prefers to use grinding apparatus, such as is used for grinding flints for pottery purposes, the materials being ground in water. After being sufficiently ground, the materials are run off into a tank and allowed to subside, and then the water is run off from the surface, and the wet, slimy mass is spread upon heated flues, or the material may be dried by other means. The pigment or substance thus prepared must then be taken and made up into paint by mixing with water or oil, and may be used in combination with colours and with dryers, according to the purpose for which it is required *Patent completed.*

1826. G. Gray and D. Cunningham. *Improvements in applying a new material to be used as a substitute for the blackening or other materials employed in casting or moulding metals.* Dated June 20, 1862.

The material used for the manufacture of this new kind of blackening or moulding material is the refuse product of bituminous shale, after this mineral has been distilled or otherwise treated so as to obtain the oil therefrom. The refuse matter of the shale is first dried by roasting, or other means, so as to render it fit for grinding; it is then ground in a suitable mill or triturating apparatus. The ground product is again dried, if necessary, and then sifted, so as to leave it in the form of a fine powder.—*Patent abandoned.*

1827. B. Fabricotti. *A polishing and grinding belt formed of leather or other flexible or pliable material, having plugs composed of emery or other gritty substance, and a proper cement inserted in it substantially.* (A communication.) Dated June 21, 1862.

The object here is to obtain a polishing belt which will retain its cutting, grinding, or polishing capacity until it is completely worn out, without requiring to be fed or supplied with emery, and to this end the patentee inserts in the belt, at suitable distances apart, plugs composed of emery or other gritty substance, and any suitable cement, the said plugs extending entirely through the belt, so as to form permanent polishing or cutting sorfaces.—*Patent completed.*

1829. F. U. Schneider and J. Snider. *Improvements in the construction of breech-loading firearms.* Dated June 21, 1862.

Provisional protection has not been allowed for this invention.

1830. J. Taylor. *An improved doffer or stripper for carding engines for preparing cotton and other fibrous substances.* Dated June 21, 1862.

This consists in the use of stripping blades arranged radially upon a cylinder or other axis, and rotating within a cylinder or shield containing apertures, through which the stripping blades project in succession only at such places as required for doffing, and retiring again, cleansing themselves of the cotton against the edges of the apertures in the cylinders. A modification of this doffer comb may be effected by arranging the blades upon a shaft passing through the shell of the cylinder, which is made hollow and of large diameter. Either may be actuated or driven distinctly, or in connection, that is, the blades may be made to drive the cylinder by contact. *Patent completed.*

1831. G. Simpson. *Improvements in machinery for working, boring, and mining or excavating tools, and mine and other pumps.* Dated June 21, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1832. H. Davenport and J. Davenport. *Improvements* *in means or apparatus for the manufacture of loom healds or harness.* Dated June 21, 1862.

This relates to the manufacture of loom healds, or harness, in which, in place of the nails, nooses are used, and the improvements have for their object to form knots to such nooses by the working of the mechanism employed in the manufacture of such healds or harness in place of such knots being produced by hand. For this purpose, according to one arrangement the patentees adopt, the threads or yarns of which the healds are produced, are conducted from bobbins lengthwise by the sides, and through the hollow end of an instrument, upon which the nooses are formed, and which serves to regulate their size. The yarns having passed out from this regulating instrument are acted upon by points or openers, and then by other points in pairs, which draw the yarn on each side of the flys or lappers for lapping on to the rig bands. Other instruments or forks then take back the yarns passing through the regulator, when pointers on each side take back such yarns, and from one of them fingers take one of the threads or yarns, and lap it over the other thread round the end of the regulator, where it is held by holders whilst the openers come into operation again. A forked slide on the fingers acts as a pusher to push the thread therein to the point of the fingers for the lapping in the proper place on the end of the regulator. A stop on the hollow end of the regulator prevents the thread being lapped on to from being drawn out of place by the lapping of the other thread. Varnish or other suitable adhesive matter applied to the knots will hold them in place when finished. *Patent completed.*

1833. J. Anderton. *Certain improvements applied to the tape-leg or sizeing machine, and in the apparatus employed therein for the purpose of improving the yarns.* Dated June 21, 1862.

Between the reed or snaith and the yarn beam the patentee places a box or trough for containing water or other liquid, and having bearings for carrying a circular brush, so that it can revolve in contact with the yarn by the passage of the yarn itself, or by other means. This arrangement is for giving moisture to the yarn, and thereby rendering it more suitable for weaving than is obtained by the ordinary machines. *Patent completed.*

1834. S. Holman. *Improvements in pumps and valves.* Dated June 21, 1862.

This relates, 1, to a novel arrangement of pump. The pump consists of a barrel or inner cylinder, made of iron or other material, placed within a cylindrical casing (which may be used as an air vessel), leaving a space all around between the inner and outer cylinder to permit the discharge of the fluid at or beyond each end of the barrel alternately. The piston, in its reciprocating motion to and fro in the barrel, operates upon the suction and delivery valves, so as to cause the water or other fluids to flow into and out of the pump, which ever way it is moved; it will thus be a double-action pump. In order to render this a cheap and efficient pump, the patentee prefers using valves made of india-rubber or other suitable material, specially arranged and constructed. The invention consists, 2, of new forms of pump valves and seats, viz., he purposes to make flexible valves of india rubber or other material in such forms and proportions as that each valve shall close an opening or space by a lateral or inclined bearing against the two sides forming the seating for the valve. 3, In the application of a double ring valve, made V form, similar to the double cap leather used in hydraulic presses, the inner ring forming the suction valve, and the outer ring the delivery valve, and operating upon seats adapted for them; or the outer ring may be made to form the suction valve, and the inner ring the delivery valve, according to the arrangement of the communicating passages. *Patent completed.*

1835. H. Gonnon. *Improved machinery for making bricks.* Dated June 21, 1862.

This machinery, which may be worked by steam, horse, or other power, is composed of a driving shaft with fly wheel; to this shaft is fitted two cams, one of which serves to raise a lever, and causes a hammer to strike the clay when it has fallen into the mould, and form it into a brick. The other cam serves to produce a movement which lifts the brick out of the mould. To this machine is adapted a kneader or crusher which prepares the clay. As the clay leaves the kneader or crusher it is cut by a knife into a size suitable to the mould used. After being struck by the hammer or mallet, it is pushed by a spring on to an apron which passes it to a board in a complete state. The shaft which carries the cams is set in motion by a wheel, and the entire machine is supported on a wooden or iron framing. By adding to or taking from the blades of the kneader, the bricks may be made of any thickness without change of mould. *Patent abandoned.*

1836. A. F. Maigron. *Improvements in winding off, carding, and spinning all thready fabrics.* Dated June 21, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1837. J. H. Redstone. *Improvements in the construction of boilers of steam engines.* (A communication). Dated June 21, 1862.

This boiler is composed of flues or tubes which hold the water to be heated in connection with the flue sheet, which is coiled in casting so as to form a series of tubes ranging vertically, and covering the whole face of the flue sheet or boiler head, or nearly so. In these tubes, in the flue sheet are perforations on the inside fitting the size of the flue, to allow it to be rivetted so as to make a steam joint. The tubes pass horizontally from one sheet or head to the other, and are rivetted or secured in the same manner as other flues or tubes in boilers. Outside, and opposite the end of the tube or flue, there is a perforation large enough to admit the tube or flue when one is to be replaced, as well as for rivetting the flue upon the inside perpendicular passage or tube forming part of the flue sheet. Across the top of the flue sheet, and connecting all the tops of the upright flues in the flue sheets, is a tube of increased capacity designed to connect the flues and serve as part of the steam space. These flue sheets are constructed with grooves and fillets fitting the sides and top of the frame-work to allow the expansion and contraction of the flues without straining them or loosening their connections with the flue sheets or heads. The whole frame-work is bolted together in the same way as a stove, the sides having a plate under the flue sheets to form the fire-box. The top is provided with a steam chest or space as follows:—Projections similar to tubes lying upon the lower surface, and leading to the centre of the plate (where there is a small chamber cast in the plate), are cored so as to form passages for the steam from the horizontal connecting tubes, which are arranged across the top of the upright tubes in the flue sheets, and by this arrangement, the flues and all the passages are accessible by simply removing the plug which closes the opening at the end of the flues or tubes. *Patent completed.*

1838. F. Tolhausen. *Improvements in apparatus for preventing collisions on railways.* (A communication). Dated June 21, 1862.

This consists of a rail jointed in the middle and at both ends, forming a double incline, placed by the side of the common rail at suitable distances on the line. This incline, or jointed rail, is kept up by balance-weights and springs, but when a train passes, it is depressed by a special wheel fixed on the locomotive or carriage axle. This depression causes a vertical rod to act on a bell-crank lever, at the end of which a wire or other equivalent link is attached, and the wire being thus pulled by the depression of the incline draws up a series of stops or projections placed at suitable intervals in advance of the moving train (600 yards, say). These stops are arranged similarly to knife blades, so as to open into a vertical position, and remain open when drawn or pushed one way, and shut when acted on the other way. Thus, supposing another train approaching in the opposite direction, a lever or fender placed on the locomotive of that train will strike against the stops and cause a bell on the locomotive to ring. There are other details. *Patent abandoned.*

1839. G. T. Bousfield. *Certain new and useful improvements in steam engine valves.* (A communication). Dated June 21, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1840. J. Lawson. *Improvements in the manufacture of carpets and other piled fabrics.* Dated June 21, 1862.

For the purposes of this invention, in producing a piled figured fabric, the patentee uses ground warp distended, as is usual between a warp beam and another beam or roller on which the fabric when finished is wound. This warp is arranged, by preference, in a vertical position, and is threaded through harness, by which it can be divided into sheds for the passage of a shuttle. For the pile yarn he employs as many beams as there are rows in the pattern, and he winds on each of these beams coloured yarns, the colours on each beam being arranged to succeed each other in the same order as they do in the row of the pattern to which the beam corresponds. Each of the pile yarn beams has attached to it a row of needles, and each pile yarn is threaded through the eye of a corresponding needle or short length of the yarn hanging down below the eye of the needle. When in the process of working it is desired to tie the pile yarn into the fabric, and produce with it a row of pile tufts corresponding with this row or line of the pattern, the pile yarn beam corresponding with this row or line is brought forward, and its needles are caused to pass through the warp carrying the ends of their pile yarns with them sufficiently far to be clear of the vertical warp; a shoot of weft is then thrown in, and, the needles having mooved back out of the way, the weft is beaten up upon the pile yarn which has been placed through the ground warp, as above described; then the needles of the same pile yarn beam are again passed through the ground warp, carrying loops of the pile yarn with them, and a pile wire is entered through these loops; afterwards another shoot of weft is thrown in, which, when the needles are withdrawn out of the way, is beaten up. A suitable cutting apparatus then divides the loops of pile yarn over the wire, and the pile beam in receding draws out the loose ends of pile yarn, leaving the loops in the fabric. The tufts to form the next row of the pattern are then similarly produced by another pile beam, and so on. *Patent completed.*

1841. E. Edmonds. *Improvements in the manufacture of felted articles, and fabrics, and in apparatus employed therein.* (A communication). Dated June 21, 1862.

This consists in combining with flat hardeners rollers or similar instruments for carrying forward through them a continuous sheet of fabric, and thus flat hardeners are enabled to operate on a sheet of any length, In order to produce better crossing and interlacing of the fibres of the wool, and a more even felt than has been before made, the sliver of wool from the scribber is not fed into the carder in the same direction as that in which it comes from the scribber (as heretofore in the manufacture of felted articles and fabrics), but transversely, or at angles to this direction. By this means the fibre of the wool, which, under the present system of making felted goods, proceeds longitudinally from one machine to the other, is reversed, and will better bear the action of the hardener. *Patent completed.*

1842. T. Wilson. *A new or improved dress-fastening, which said fastening is also applicable to the fastening of bands, and belts, and other like purposes.* Dated June 23, 1862.

This dress-fastening consists of two parts, one of which is fixed or sewn to one part of the article of dress, and the other to the other part of the article of dress. One of the parts consists of a flat piece of sheet metal, somewhat resembling a horse-shoe in form, that is, it consists of two parallel bars joined at one end by an arch or cross-piece. This part of the fastening has ears, or projections, in its outer edge, by which it is attached by sewing to the garment. These ears are near the free ends, and at the arch or cross-piece. All the parts of this part of the fastening are in the same plane. The other part of the fastening consists of a disc, or button, fixed to the article by its middle or otherwise. The button is inserted under the free ends of the horse-shoe shaped piece, and is passed between the parallel bars until it arrives at the curved junction of the said bars, when the connection of the two parts is complete. In separating the two parts, it is only necessary to press the button, or disc, with a simple pressure in a direction opposite to that by which it was connected with the other part, when it readily passes from under the other part. *Patent completed.*

1843. H. McKenzie and P. Ramsay. *Improvements in cylindrical or circular brushes, or rollers, for various manufacturing machines.* Dated June 23, 1862.

Here the object is to produce an improved cylindrical or circular surface, which, according to the velocity of rotation imparted to it, will have a brushing action or a frictional elastic adhesion, and which is susceptible of useful application in various manufacturing machines wherein rotating brushes or rollers are required. The improved surface is produced by fixing short pins, or projections of elastic rubber, either vulcanized or not, in the cylindrical or circular surface of the rotatory brush or roller, and this backing surface may consist of uncovered wood or other hard substance, or it may have a covering of elastic rubber or other light material, through which the rubber pins are made to project. *Patent abandoned.*

1844. H. Ponsonby. *Improvements in topsail sheets' bits or bolts.* Dated June 23, 1863.

This consists in the use of an apparatus made of iron, with pins, studs, eyelets, or other projections to which the respective sheets are made fast at either side, and which apparatus, by having its ends stepped in bushes, is free to make a partial revolution with the lower yard, under the slings of which the patentee prefers placing it in a vertical line.—*Patent completed.*

1845. G. Haseltine. *Improvements in machinery for mowing and reaping, the driving gear employed being applicable to machines for other purposes.* (A communication. Dated June 23, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1846. A. Webster. *Improvements in apparatus for boring slate.* Dated June 23, 1862.

This invention relates to certain improvements in the arrangement and construction of machinery for boring slate, more particularly in the form used for roofing purposes, so that each slate may be perforated at one or more places at a single operation, the perforations being much improved in form from those produced by the usual mode, and suited to receive countersunk-headed nails, whilst the loss from breakage of slates in boring is greatly reduced or wholly avoided. This invention consists, primarily, in applying a combined punching and drilling movement to the tools operating upon the slate, and shaping these tools and their matrices so as to produce countersunk or otherwise shaped holes. And, secondly, in certain arrangements of parts and mechanism for producing the necessary compound movement of the tools from a simple and intermittent hand action. *Patent completed.*

1847. W. Barr. *An improved manufacture of raised or brocaded fabrics woven in cotton or flux, either alone or in combination with wool.* Dated June 23, 1862.

This invention consists in making raised or brocaded fabrics, such as are or may be employed for under-garments, collars, trimmings, and other such like uses, and which require to be formed of a cotton, linen, cambric, muslin, or any other suitable material, or of any or all of such materials, in combination with wool, by weaving the same in a jacquard loom forming the pattern or brocade from the weft. *Patent completed.*

1848. R. Cook. *Improvements in the construction of pianoforte actions.* Dated June 23, 1862.

The chief object of this invention is to ensure the proper action of the "hopper," or instrument employed in pianoforte actions, to throw the hammer against the strings, and then suddenly to release it, that it may, after delivering a blow, instantly fall back to its quiescent position ready for repeating the operation. Hitherto the hopper, by reason of damp gaining access to that portion of its surface which comes in contact with the lever for transmitting the motion to the hammer, or to the hammer butt, has been very liable to stick, and produce what is called the blocking of the strings, thereby destroying the vibration. To avoid this defect, the patentee employs a metallic contact surface to work against the buff leather or other soft covering of the lever or hammer butt. *Patent completed.*

1849. A. Ripley. *Improvements in the construction of damper governors or regulators.* Dated June 24, 1862.

This invention relates to an improved method of regulating the draught in boiler and other flues. To effect this the patentee mounts on any convenient place adjacent, a cylinder having a piston or plunger and rod; from the bottom of the cylinder he leads a pipe connected with the boiler in the form of a double bond; this he fills with oil in quantity equal to the capacity of the cylinder when the piston is at the extreme stroke, and forces up the piston in the cylinder by this means. The oil serves to lubricate the piston and makes it work easy. The top of the connecting rod is attached to a long lever, one extremity of which acts upon a rod or chain connected with the damper, and the other end of the lever carries an adjustable weight to regulate the damper. The action is as follows:—The weight on the lever indicating, say, 40 lb. per square inch, the steam will have no effect upon the oil, and therefore on the piston, until it gets over that amount; the piston will then be raised, and the damper closed, and the generation of steam checked until the pressure is reduced; then the piston will descend and the damper will be opened. *Patent completed.*

1850. W. Hargreaves and G. H. Leather. *Improvements in machinery or apparatus for combing wool, hair, silk, cotton, flax, and other fibrous substances.* Dated June 24, 1862.

This invention relates to combing machinery, in which the material to be operated upon is drawn off in a continuous sliver of clean wool or other fibre, and also a continuous sliver of noil, dirt, and short fibre. The principle the patentees proceed upon is to mount a revolving dial comb, with its teeth or pins all pointing towards the centre on an iron framework, and within the dial comb they place a revolving roller or nipper, having grooves turned in it for the teeth or pins of the dial comb to travel in it. The circular nipper revolves upon its own axis, which is firmly fixed to a sliding frame, and this frame is acted upon by a spring and an adjusting screw, so as to press the revolving nipper against one side or the circular dial comb. When, therefore, the wool or other fibre is brought by the action of the machine to this point of the circular dial comb, it is by this revolving nipper firmly pressed into the pins and against the inner side of the comb, and whilst there the projecting end of the wool or other fibre is brought within the action of a porcupine card, or any other suitable instrument revolving at a greater velocity than the dial comb, whereby it is cleansed of its noil, dirt, and short fibre. The noil, dirt, and short fibre taken by the porcupine or card is passed from the porcupine by means of a revolving brush and cleansing card (or by any other well known means) in a sheet or sliver. By the further revolution of the dial comb the cleansed portion of the fibre is released from the action of the circular nipper, and passes under a set of stationary blades, to prevent the fibre from rising above the points of the teeth or pins of the comb, when it approaches a pair of ordinary drawing-off rollers, by means of which it is drawn off through the teeth of the dial combs. After passing by the drawing-off rollers, the portion of fibre left in the teeeh of the dial comb is brought by the further revolution of the comb to a set of stationary inclined blades, by means of which the fibre is raised clear out of the teeth or pins of the dial comb, and remains free from the teeth during a considerable portion of the revolution of the comb, and during this period is pushed forward by the face plate. By the further revolution of the dial comb the wool or other fibre becomes fixed in the teeth of the comb, and approaches the side of the comb against which the circular nipper is pressed, and its projecting end is there cleansed, as before described. The dial comb is fed or filled all round its circle of pins with the fibre to be operated upon, so that the different operations already described are continuously carried on, producing a continuous sliver of cleansed fibre, and a continuous sliver of noil, dirt, and short fibre. The face plate is made with a series of holes for the wool or other fibre to pass through to be operated upon by the dial comb. The creel has bobbins or cans to hold the wool or other fibre intended to be operated upon. Both the creel and face plate are fixed on one shaft, and geared to revolve at the same speed as the dial comb. The iron frame which carries the shaft of the creel and face plate is placed behind the dial comb, and can be adjusted to an angle with the dial comb, so as to give a greater or less length of fibre to be operated upon. *Patent completed.*

1851. T. Carr. *An improved machine for grinding, kneading, washing, and other like purposes.* Dated June 24, 1862.

This invention relates to those mills or machines known as edge-runners, and to that description in which the pan is rotated, and consists in driving or rotating on their axles one or both of the edge-runners, as well as the pan, but by a separate driving gear, so that the former acts independently of the latter, and a greater or less speed can, consequently, be given them than they would acquire from the mere rotation of the pan; while at the same time they are left as much at liberty as the ordinary edge-runners are to be freely raised by any substance they are unable to reduce passing below them, without stopping or injuring the machine. This invention also consists in suspending (in some cases) the stones or edge-runners, in such a manner that they are prevented from coming into immediate contact with the pan itself, or, when empty, of resting upon it, being so supported that they can be gradually raised or lowered at pleasure, so as to increase or diminish, as required, their proximity to the pan. The periphery of the edge-runners, or the surface of the pan, or both of them, may, when a more cutting action is required, be fluted or otherwise grooved or furrowed; or, instead, knife edges, spikes, teeth, or hooks may be inserted, as found most appropriate to the material to be treated. This invention further consists in the application, where required, of a lever or its mechanical equivalent, acting, by means of weights or springs on the said edge-runners, in such a manner as to be readily adjustable for the purpose of augmenting or lessening to any required degree the pressure on the material to be operated upon. *Patent completed.*

1852. T. Desgrandschamps. *A new mechanism of distribution with motion from the rod, applicable to any kind of steam-engines.* Dated June 24, 1862.

These improvements are applicable to all steam-engines, and offer the following advantages:—1, the slide valve opens very rapidly at each end of the length of the stroke of the piston, the opening of the inlet hole, or steam port, being nearly complete about the twentieth of the stroke, which, on the one hand, permits the steam to arrive, as it were, simultaneously behind the piston at the beginning of its stroke, and to act immediately with all its expansive force; and, on the other hand, permits this same steam, when it has pushed the piston to the end of its stroke, and thus completed its work, to escape freely without producing the back pressure which is the fault of existing distributors. 2, This distributor permits the steam to act by expansion at all points of the stroke of the piston at the will of the engineer, starting from the fourth of the stroke. 3, Certain pulleys, rods, eccentric rods, and other pieces, are replaced by a more simple apparatus, which may be kept in working order at less cost. The movement which works this distributing apparatus is taken from the connecting rod. This means is not new in itself, but in its application, which consists in transmitting the motion of the connecting rod to a slide, which forms the principal part of this invention, and which, by its particular arrangement and combination with the other parts of the mechanism constituting the distributing apparatus, forms a whole by which novel results are obtained, no distributor yet constructrd permitting the advance of the slide valve to be varied at will, and this is the principal property of the slide above mentioned. *Patent abandoned.*

1853. G. Collier and J. W. Crossley. *Improvements in means or apparatus for hot-pressing, which improvements are also applicable to other heating purposes.* Dated June 24, 1862.

This invention consists in making such press-plates of softer or more pliable metal, capable of being repeatedly cast in the same moulds, and the inventors employ, for the purpose, zinc, pewter, or a combination of these with lead, tin, or other metals, and they form the moulds of iron, or other hard or comparatively hard metal, or of plastic composition. They, by preference, cast the plates in parts, and of such form that, when soldered or otherwise fastened together, suitable hollow passages are left therein, for the proper circulation of the media used either for heating or cooling; and to prevent the expansion of the plates in the middle by reason of the internal pressure of the heating or cooling media, there are dovetailed or other projections in one part of the plate, which fit into corresponding recesses in another part of the plate. *Patent abandoned.*

1854. W. Bayliss. *An improved strainer for straining and tightening wire for fencing and other purposes.* Dated June 24, 1862.

This invention consists in setting up in a frame or stand a roller or pulley working through side supports, having a deep flange on one side, and an elastic packing on the other, secured on the extended axis of the roller or pulley in any convenient way. On the inside of the front flange a series of inclines are formed, which travel over a corresponding projecting incline formed on the face of the support, for preventing the roller or pulley from revolving but in one direction. The elastic packing on the outer end of the pulley or roller exerts its force in such manner that, as the pulley or roller is turned around, it will traverse parallel with its axis according to the rise and fall of the inclines, which, as the one in action passes over the termination of the incline on the support, the extreme ends of the inclines will be brought in radial contact, thereby preventing the roller turning in the reverse direction to the required strain. As for instance, in applying this simple apparatus to the straining of wire, the wire is first secured to the roller or pulley, and by placing the apparatus against a suitable abutment, the roller or pulley has to be turned with a fixed or portable winch handle, or other suitable means, and as it revolves, so the wire is held and strained to the desired tension, when it may be permanently secured in any suitable or ordinary way. *Patent abandoned.*

1855. J. Johnston. *Improvements in hats.* Dated June 24, 1862.

This invention relates to improvements in the manufacture of cloth hats, or those in which the bodies are covered with a woven fabric, in place of being formed of felt. Under one modification or system of manufacture the calico, or other similar material of which the body of the hat is formed, is prepared with shellac in the ordinary way. A piece of cloth, of a size suitable to form the under surface of the hat, is laid down, and upon this is laid a corresponding piece or sheet of the prepared calico, buckram, or other suitable material for forming the body. On the prepared upper side of the buckram is laid a piece of oiled cloth, paper, silk, or other suitable waterproof material. The whole of the fabrics are then lifted and laid upon a block, on which a secondary block or mould is caused to descend, and this block being heated, the several fabrics are caused to adhere by means of the intervening coatings of shellac. The hat so far completed, is now removed from the block, and the surface of the oil-skin or other waterproof material is coated with shellac in the ordinary manner. The piece of cloth which forms the outer covering of the hat Is now laid on, and this covering is caused to adhere to the body by submitting it to the blocking operation. The edges are then trimmed, bound, and the hat lined, which completes the manufacture, the hat produced being perfectly waterproof. *Patent abandoned.*

1856. G. Gray. *Improvements in the manufacture of wheels.* Dated June 24, 1862.

For the purposes of this invention, a peculiar construction of metal nave is used, by preference of cast iron. Each nave is cast in two parts, in one of which the several mortices or sockets for the inner ends of the spokes are formed, and such sockets or mortices are made by preference with parallel sides, the mortices radiating from the centre of the nave. It is preferred that the angular parts of the nave which come between the spokes, should be cast hollow, in order to obtain lightness. The second or outside part of the casting, simply consists of an outside cover to the nave, which is fixed to it by means of screws, the ends of which screw into an interposed disc or flat ring of wrought iron, and this disc or ring is fixed to the first mentioned part of the casting by means of screw bolts and nuts, the heads of which bolts are countersunk in the disc or ring, and the screw bolts pass through holes through the angular parts of the casting which come between the spokes. In putting a wheel together, the wrought iron disc or flat ring is put into its place, and so that it does not come in contact with the casting, but is held by moveable pieces a short distance away from it; the screw bolts are then passed through the ring and the casting, the nuts are then screwed up, and the ends of the wood spokes are driven into their places, the tenons being slightly taper. The flat ring or disc does not fit close around the cylindrical central part of the casting of the nave, against which the inner ends of the spokes come when they are driven home, and the fact of their being driven home will at once be seen through openings in the centre of the ring or disc. The spokes having been driven in their places, the outer plate is put into its place, and fixed by screws to the wrought iron disc; should the inner ends of the spokes shrink, the disc may be tightened by the nuts. *Patent abandoned.*

1857. E. C. Nicholson. *Improvements in the preparation of colouring matters applicable to dyeing and printing.* Dated June 24, 1862.

For the purpose of preparing a blue coal-tar dye soluble in water, either alone or mixed with acid or alkali, the patentee employs the following process:—He takes by preference the substance known as "Blue de Lyon," or that known as "Azaline," these being blue colouring matters obtained from aniline and similar bases. He extracts all soluble matter from it by boiling it with water containing sulphuric acid. He employs for this purpose the said acid in the proportion of about 4 oz. by weight to every gallon of water. When all or nearly all the soluble matter is extracted, he collects the insoluble matter and dries it thoroughly and completely. He then takes this substance reduced to powder, and adds to it about four times its weight of sulphuric acid, say, Sp Gr 1,845 (*i.e.*, concentrated sulphuric acid of commerce), and he raises the temperature of the mixture to about 300 degrees Fahrenheit, and keeps it stirred until all is dissolved; and he then maintains it at about this temperature until a sample when added to water is entirely dissolved. If the temperature is raised too high, sulphurous acid is evolved, and the dye gradually destroyed. The acid solution can be diluted and used for dyeing or printing in the ordinary way; or, if too acid, the excess of sulphuric acid may be removed by lime or other suitable alkali; or if an excess of lime be added, the sulphuric acid is entirely precipitated in the form of sulphate of lime, and a colourless solution is obtained which, when neutralized with any vegetable or other acid, developes the improved soluble blue dye; or he finds that the excess of acid may be separated from the acid solution by adding to it, say, four times its bulk of water, and then filtering, for the colour, although soluble in concentrated acid and also in water, is practically insoluble in water containing a large quantity of acid, or the slight loss of colouring matter which would arise from the use of water in this manner may be avoided by the use of brine in place thereof. *Patent completed.*

1858. W. Clark. *Improvements in hernial and other orthopedic apparatus, and in pessaries and other instruments.* (A communication). Dated June 24, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

1859. W. A. F. Mennons. *Improvements in steam-boiler furnaces.* Dated June 25, 1862.

This invention consists in the application to the fire-boxes of steam-boiler furnaces of an inner mantel or diaphragm, so arranged as to form a reverberating chamber, in which are effected the heating of the atmospheric air required for the combustion of the smoke, and its distribution over the ignited surface of the fuel in the grate. *Patent completed.*

1860. S. Brooks and S. Denton. *Improvements in machinery for spinning and doubling.* Dated June 25, 1862.

This invention is applicable to the copping motion of spinning and doubling machines, and it consists in an improved combination of parts for winding and binding the yarn on the spindles in the form of a cop, whereby more yarn is wound in each cop, and the cop is less liable to break or rove off than when the cops are built by the machinery now in use. In performing this invention the inventors make use of a short copping motion attached to the carriage of the mule or twiner; above the copping rail is a bowl jointed to the end of a lever, which vibrates on a fixed stud; to the stud of the bowl a link is jointed, which has a stud for another bowl on which the end of the faller leg connected to the faller shaft rests. By this means, as the copping rail gradually lowers in building the cop, the faller is gradually raised, and its position is governed so as to build the nose of the cop of the required shape. The second part of the invention consists in varying the position of the shaper plates by means of a screw tapped into one plate and passing through a projection on the other. The third part of the invention consists in regulating the number of teeth to be taken up by the rotchet wheel of the screw of the copping motion by a set screw passing through the lever, to which the catch of the ratchet wheel is jointed. The fourth part of the invention is applicable to mules having a long lever, as in Robert's self-actors, and it consists in an improved arrangement of parts for governing the long lever when the changes should take place. *Patent abandoned.*

1861. J. Blair. *Improvements in the manufacture of wadding.* Dated June 25, 1862.

This invention consists in the application, to the manufacture of wadding, of the fibres produced in tearing up the bags in which Surat and other cotton is generally imported into this country. This fabric is known as Surat tares, or Surat bagging, and it is made of a coarse fibre or grass, somewhat like jute. The fibres produced from this bagging the inventor now uses as a substitute for, or in combination with, cotton for manufacturing wadding, thus improving the quality, and economizing the production. *Patent abandoned.*

1862. W. Clark. *Improvements in ploughs.* (A communication.) Dated June 25, 1862.

Ploughs, as usually constructed, are formed of two principal parts – the "share," which penetrates the ground to a certain depth, and then raises it, and a "mould-board," which, immediately after the first operation, reverses the soil which has been thrown up by the share, so that the under part shall come to the surface, and *vice versa*, and so as to plough up the ground in furrows. These two principal parts of the plough, viz., the share and the mould-board, are fixed and rigid, the one stirring up the ground, and the other turning it over. This rigidity, which is the same in all ploughs, causes the ground to accumulate and clog in rising on the mould-board, which greatly increases the power necessary for turning it over, and requires the use of implements of great strength; at the same time it limits the depth of the furrows, and but imperfectly opens the ground. According to this invention, the inventor makes the mould-board moveable on an axis, fixed at any suitable part of the plough-frame. It is inclined in the direction of the furrow, so that, when the rotary mould-board receives the pressure of the ground thrown up by the plough-share, it is caused to turn, carrying with it the earth bearing on it, which it raises in its rotary movement, and turns it over so as to completely open the ground. This invention may be applied to all kinds of ploughs, whereby the mould-boards are made to rotate on an axis, and turn by the pressure of the ground as it is thrown up. The mouldboard, on rotating, carries the ground with it without difficulty, which, being thus opened up, the use of crushers or rollers may be dispensed with. *Patent completed.*

1863. G. Haseltine. *Improvements in vaporizing lamps.* Dated June 25, 1862.

The nature of this invention consists in mingling the vapour of coal oil with atmospheric air, either in a tube above the burner where the tube is exposed to an intense heat, and from which the combination descends to the burner, or in conducting the vapour after it is combined with air into a chamber above the frame, for the purpose of heating the mixture from which it descends to the burner. An elastic diaphragm, operated by a spring, is employed to force the fluid up from the body of the lamp into the upper end of the tube, where it is vaporized, and the vapour forced out through a minute aperture. A needle-shaped valve, operating within the said tube, is employed, the point of the needle being adapted to the said aperture operates in and through the same, and prevents the aperture from becoming clogged by condensed matter, and thereby obstructing the passage of gas or vapour. This needle is prolonged downward within the tube, or, what is the same thing practically, a small rod is connected with the needle, the said rod reaching to a point beyond the influence of the heat of the lamp, where it is connected with any suitable device for conveniently operating the needle to open and close the aperture, thereby regulating the flow of the gas. When this lamp or apparatus is used for cooking, and other domestic purposes, a heater is employed to vapourize the oil. *Patent abandoned.*

1864. F. Tolhausen. *Improvements in locks or locking apparatus.* (A communication). Dated June 25, 1862.

This improved lock or locking apparatus consists of a bolt or bar which is lodged horizontally either in the lid or the body part of the trunk or box, and is acted upon by coiled springs so as to shoot forth and enter one or more eyes or hooks attached to either part of the trunk, when these two parts are brought home together. The said closing bolt may be constructed in various ways; it may have several hooks, which are intended to enter the eyes on the other part of the trunk. The closing bolt, whatever may be its shape, is entirely contained in the trunk, and the aperture by which access is had to it is covered with a button, or any other ornamental device. For the purpose of unlocking, the bolt is either screwed, tapped, or otherwise shaped at one of its ends, so as to allow inserting a special tapped, screwed, or other key, by which the bolt is drawn or shifted, and the eyes or staples released, when an obstructing piece, acted on by a spring, rises to keep the bolt out and ready to act on closing the lid again. *Patent abandoned.*

1865. A. Bayley. *Improvements in lamps.* Dated June 25, 1862.

The object of this invention, which relates principally, but not exclusively, to those lamps for burning paraffin, rock, and other spirit oils, is, 1, To dispense with the glass chimney or globe usually employed, and yet to supply a sufficient quantity of atmospheric air to maintain steady combustion, by simply lighting the lamp, but without the use of any mechanical motion. Over the liquid container of the lamp, which the inventor prefers making of a semi-spherical or conical shape, or over a cap of similar or other suitable form, secured above the liquid container, but fitting air-tight to or around the wick tube, he fits a cap, having the same general outline, and by fenders, or other arrangements, keeps it a distance from the liquid container or cap first mentioned, thus leaving a truncated space for the supply or ascension of air to the point of combustion. The distance between this outer cap and the inner one, or liquid container, is greater at the bottom or air entrance than at the top, towards which latter it gradually diminishes, and where the air, having become heated in its passage through the said truncated space, finally commingles with the vapours from the wick, and impinges on the flame, thus supporting a bright and uniform light. 2, To supply a sufficient and uniform quantity of air to lamps having chimneys or globes. To effect this he employs the air supply arrangement first hereinbefore described, and fixes a gallery or carrier on the outer cap, either so constructed that when the chimney or globe is held in position it will entirely exclude the air, or by leaving small openings it will admit a sufficient air supply to make perfect combustion of the oil used. *Patent abandoned.*

1866. C. C. Steenstrup. *An improved can or vessel for containing lubricating or other fluids.* Dated June 25, 1862.

This invention consists in constructing a can or vessel, principally intended for lubricating purposes, in such a manner that the oil or other lubricating fluid contained therein is ejected from the same in determined quantities, and with a certain force, which may be regulated at the pleasure of the manipulator. For this purpose the inventor fixes inside the can or vessel a small cylinder or pump barrel, which has one aperture through which it communicates with the interior of the can, and a second aperture through which it communicates with the spout of the can to which it is attached. Both apertures are closed by valves; that to the first named aperture opening inwards, similar to the suction valve of an ordinary pump, whilst that to the last named aperture opens outwards, similar to the delivery valve of a force pump, and both these valves are pressed down on their seats by means of small springs. Beyond both the above-named apertures is a piston capable of being worked up and down inside the cylinder to a variable extent by means of a piston-rod passing out to the outside of the can or vessel, where it is provided with a knob or disc which is depressed by the hand. A spring pressing against the under side of this knob forces the piston rod, and with it the piston back into a certain position after it has been depressed by the manipulator, and maintains it in this position when it is not acted upon. Projecting from the outside of the can or vessel by the side of the piston rod is a graduated scale, the divisions upon which indicate the distances to which the piston must be depressed for a certain number of drops of oil or other fluid to be ejected from the spout of the can or vessel. *Patent abandoned.*

1867. E. H. Heech and J. F. Windhausen. *Improvements in caloric engines.* Dated June 25. 1862.

The specification of this invention comprises a great amount of detail, but the main feature of the invention is the use of compressed air, mixed with gases or products of combustion, for driving the engines constructed as described. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Sept. 1, 1862.

2422. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the manufacture of braid, and in machinery or apparatus employed therein. (A communication.)

Dated Sept. 20, 1862.

2581. B. Hotchkiss, New Haven, United States. Atmospheric trip hammers.

Dated Oct. 17, 1862.

2804. H. Wickens, 4, Tokenhouse-yard, solicitor. Improvements in machinery for making nails. (Partly a communication.)

Dated Nov. 1, 1862.

2959. W. E. Newton, 66, Chancery-lane, civil engineer. Improved apparatus for drying grain and other substances. (A communication.)

Dated Nov. 10, 1862.

3027. J. B. Savoine, St. Pierre, near Calais, architect. A kitchen range adapted for cooking, warming the apartments, and generating gas for the use of private families, hotels, or gentlemen's country seats.

Dated Nov. 29, 1862.

3203. T. Evans, Cross-street, Abergavenny, boot and shoe manufacturer. Improvements in coverings for the leg and thigh known as antigrophilos.

Dated Dec. 8, 1862.

3291. J. Hilliar, Balsall-heath, manager of works. Improvements in ventilating, and in the exclusion of dust or draught, insects, or other animals from apartments, carriages, or other confined spaces.

Dated Dec. 10, 1862.

3312. A. P. Price, Lincoln's-inn-fields, consulting chemist. Improvements in the manufacture or production of blue colours. (A communication.)

3813. D. Chalmers, Dundee. machinist. Improvements in the preparation or manufacture of textile materials, and in the machinery or apparatus used therein.

Dated Dec. 17, 1862.

3374. T. C. Barraclough, Manchester, machine agent. Improvements in machinery for spinning, twisting, and rolling tobacco. (A communication.)

Dated Dec. 22, 1862.

3411. F. C. Bakewell, 6, Haverstock-terrace, Hampstead. Improvements in transmitting and receiving communications by means of electricity.

Dated Dec. 23, 1862.

3421. C. Pieper, Alma-place, West Gorton, near Manchester, engineer. A new improved governor for steam engines, turbines, water wheels, and other machinery with valvular arrangements, to regulate the speed of the same.

3428. J. Whitley and J. W. Burton, Leeds. Improvements in the construction of the permanent way of railways, which improvements are also applicable to railway wheels.

Dated Dec. 24, 1862.

3431. S. Haslam, Bolton, warper, and A. Eatough, carder. Improvements in machinery or apparatus for preparing cotton or other fibrous materials to be spun.

3433. J. Broadbent, Manchester, and J. Robinson, Latchford, Warrington, cotton spinners. Improvements in machinery for opening and cleaning cotton and other fibrous materials.

3435. A. P. Tronchon, 2, Rue Sainte Appoline, Paris. Some improvements in the construction of fire arms.

3437. W. C. Galloway, Glasgow, pianoforte teacher. Improvements in pianofortes.

3438. W. Henderson, St. Rollox, Glasgow, chemist. Improvements in obtaining iron and steel from certain ores and residual products.

3439. W. Clark, 53, Chancery-lane, engineer. Improvements in the means of applying heat to the feet in boots, shoes, and otherwise, part of which improvements is applicable to other heating purposes. (A communication.)

3441. J. Fairless, Forth Banks, Newcastle-upon Tyne, machine broker. Improvements in apparatus or machinery for milking cows.

3443. E. Stevens, 139, Cheapside. Improvements in machinery for preparing dough and paste suitable for making bread, biscuits, pastry, cakes, and similar articles.

3445. J. and W. Lord, Rose Hill Iron Works, Bolton. Improvements in machinery for fluting rollers, used for preparing, spinning, and doubling fibrous materials.

3447. D. G. Hope, Grays, Essex, civil engineer. Improved machinery for obtaining and applying motive power.

3451. R. Knox, Swinton-street, Gray's-inn-road. Improvements in the manufacture of metallic pens.

Dated Dec. 26, 1862.

3452. W. Clark, 53, Chancery-lane, engineer. Improvements in firearms. (A communication.)

3453. C. F. Varley, Fortess-terrace, electrician. Improvements in electric telegraphs.

Dated Dec. 27, 1862.

3457. M. F. A. Courtois, Paris, gentleman. Improvements in wax or other candles and torches.

3459. J. Petrie, Rochdale, engineer. Improvements in slide valves for steam engines.

Dated Dec. 29, 1862,

3461. J. G. Taylor, Paris, merchant. Improvements in dress fastenings, and in the ornamenting thereof.

3463. J. H. Riddell, 155, Cheapside, stove and boiler manufacturer. Improvements in stoves.

3465. F. Tolhausen, 17, Faubourg Montmartre, Paris. The use of petroleum or coal oil as fuel, and also for the machinery and apparatus to be employed for this purpose. (A communication.)

3467. C. E. Wilson, Monkwell-street, City, manufacturer. Improvements in articles of wearing apparel for the neck.

Dated Dec. 30, 1862.

3470. J. Johnston, Pinstone-street, Sheffield, plumber and glazier. An improved surface refrigerator.

3471. J. Robson, jun., South Shields. Improvements in ornamental fittings for domestic stove grates.

3473. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in the manufacture of saddles. (A communication.)

3474. F. B. Anderson, Birmingham, manufacturer. Improvements in watches and other time keepers.

3475. W. Bowser, engineer, and H. Bowser, ironfounder, Glasgow. Improvements in coating or protecting iron or steel with another metal.

3477. J. E. Carter, 3, Brownlow-mews, Gray's-inn-lane. Improvements in chimney tops.

3480. C. Beslay, 11, Rue Ménilmontant, Paris, civil engineer. Improvements in steam engines.

Dated Dec. 31, 1862.

3482. W. B. Adams, Holly Mount, Hampstead, engineer. Improvements in railways and tramways.

3484. J. S. Smith, Britannia, near Bacup, Lancaster, manufacturer, and J. Hardman, overlooker. Certain improvements in power looms for weaving.

3486. W. Clark, 53, Chancery-lane, engineer. Improvements in the arrangement of the parts of railway trains, and in the application of power for their propulsion. (A communication.)

Dated Jan. 1, 1863.

4. M. E. Bowra, Upper Norwood, manufacturer, and A. E. Francis, 10, Tokenhouse-yard, gentlemen. Improvements in the manufacture of elastic fabrics.

Dated Jan. 2, 1863.

12. W. A. Distin, Tavistock-row, Covent-garden. Improvements in pipes for smoking tobacco or other herbaceous compounds.

14. C. Eyland, Walsall, manufacturer. An improvement or improvements in the manufacture of buckles.

16. A. Bamford, Belle Flat-street, Richard-street, R. Blomley, Taylor-street, Whitworth-road, R. Taylor, 67, Manchester-road, and J. Lett, 9, Water-street, Rochdale. Improvements in looms for weaving.

18. W. H. Muntz, Milbrook. An improved method of attaching sheathing to iron or other vessels.

20. J. E. Dowson, 38, Dowgate-hill. Improvements in the manufacture of wrought metal piles, columns, and shafts.

22. A. S. Bolton, Birmingham, manufacturer. Improvements in the manufacture of wire.

Dated Jan. 3, 1863.

24. E. Skull, High Wycombe, Bucks, manufacturer, and E. Mealing, chair maker. Improvements in chairs and other seats or apparatus for sitting or reclining on, which improvements are also applicable to tables.

26. S. White, Suffolk-grove, Southwark, engineer. Improvements in the method of, and apparatus for, purifying, bleaching, and refining oils and oily and fatty matters.

30. W. E. Newton, 66, Chancery-lane, civil engineer. An improved method of firing or discharging cannon and other firearms, a part of which invention is applicable generally to the firing of charges of powder. (A communication.)

Dated Jan. 5, 1863.

32. H. Yates, Birmingham, edge tool manufacturer. Improvements in machinery used in the manufacture of shovels and spades, and for raising and shaping metals for other purposes.

34. J. Howard and J. Bullough, Accrington, iron founders and machine makers. Improvements in warping and beaming machines.

36. A. Monnet, 5, Rue de la Platiere, Lyon (Rhone), France. Improvements in twisting and throwing silk and other fibres.

38. H. Chamberlain, Langley Fawley, engineer. Improvements in generating and condensing steam, and evaporating liquids, and in the apparatus employed therein.

Dated Jan. 6, 1863.

42. C. T. Judkins, 22, Ludgate-street, sewing machine manufacturer. New alloys. (A communication.)

48. E. V. Gardner, Berners-street, professor of chemistry. Improvements in the treatment of petroleum and mineral oils, and in apparatus employed therein.

52. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in rocket torpedos, and in the apparatus for directing the flight of the same under water. (A communication.)

Dated Jan. 7, 1863.

58. W. Clark, 53, Chancery-lane, engineer. Improved media for advertising. (A communication.)

60. G. A. Huddart, Brynkir, Carnarvon, gentleman. Improvements in buttons.

62. G. Dowler, Birmingham, manufacturer. Improvements in the manufacture of match boxes.

Dated Jan. 8, 1863.

68. A. Guild, Dundee, gentleman. Improved machinery for breaking and cleaning flax, hemp, and other fibre yielding plants. (A communication.)

INVENTION PROTECTED FOR SIX MONTHS BY THE DEPOSIT OF A COMPLETE SPECIFICATION.

Dated Jan. 8, 1863.

67. L. Hull, Massachusetts, United States. Having reference to the treatment of ground caouchouc, and for the purpose of rendering it elastic or improving its elasticity, as well as imparting to such caoutchouc other useful properties.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette.*

2480. F. Selby. Traction engines.

2482. J. Walker. Oil presses.

2483. T. Fleitmann. Manufacture of copper from copper ores.

2490. A. Barclay. Traction engines.

2495. W. A. Munn. Capping, loading, and closing cartridges.

2496. T. Steel. Treating soap suds.

2503. L. C. Hoyau. Marking time.

2504. J. Thomson. Treatment of vegetable fibres.

2505. A. Barclay. Locomotive, boring, and winding engines.

2508. P. Ward. Manufacture of a double sulphide of calcium and sodium.

2511. A. E. H. B. Butler. Straightening and polishing cylindrical bars of iron and other metals.

2519. H. Higgins. Opening, cleansing, or carding fibrous materials.

2522. H. J. Lewis. Engines.

2525. T. W. Cowan. Pumps.

2529. E. G. Chant. Self-binding portfolios, and holders for newspapers.

2532. E. Balmforth. Finishing textile fabrics.

2533. W. L. Tizard. Construction of ships, vessels, cupolas, and forts.

2541. S. Flexen. Ventilating carriages.

2543. R. Moreland, jun. Preparing and cutting hops.

2556. L. Mond. Obtaining hypo-nitric acid and nitric acid from nitrate of soda.

2562. J. W. Woodford. Driving and drawing piles, also for raising soil.

2563. T. Watts. Thrashing machines.

2581. B. Hotchkiss. Hammers.

2593. T. Knowles, J. Houghton, W. Knowles, and W. Houghton. Looms.

2597. R. A. Brooman. Lighting apparatus. (A communication.)

2604. R. A. Brooman. Composition for painting. (A communication.)

2637. J. Brown. Carding engines.

2645. H. Ellis. Improvements in the manufacture of compounds of silica.

2702. C. Chinnock. Axle boxes.

2775. J. H. Johnson. Sewing machines. (A communication.)

2979. J. H. Johnson. Hanging, arranging, and operating ordnance. (A communication.)

3203. T. Evans. Coverings for the leg and thigh.

3336. J. W. Baker. Spinning fibrous materials.

3478. W. Richards. Cannon and other firearms.

3484. J. S. Smith and J. Hardmann. Looms.

8. J. Jones. Finishing or stiffening textile fabrics.

24. E. Skull and E. Mealing. Chairs and other seats.

30. W. E. Newton. Firing or discharging cannon and other firearms. (A communication.)

68. A. Guild. Machinery for breaking and cleaning flax, hemp, and other fibre yielding plants. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Jan. 16th., 1863.

2049. T. B. Daft.
2051. J. Willcock.
2057. C. A. Day and T. Summers.
2060. R. Barrett.
2061. R. A. Brooman.
2070. E. Bazin.
2071. W. E. Gedge.
2072. T. Davey.
2119. A. Lahousse.
2158. W. E. Gedge.
2163. J. Benyon.
2165. W. Clark.
2373. J. A. Coffey and T. Redwood.
2872. J. Carpendale.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

100. M. A. F. Mennons.
116. S. Fearnley.
129. A. Chaplin.
127. G. J. and T. Barker.
147. G. H. and H. R. Cottam.
120. J. F. Spencer.
130. W. W. Hewitson and B. Walker.
149. F. J. J. De la Ferte.
299. G. A. Biddell.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

120. J. Fowler.
122. H. R. Worthington.
162. P. L. T. Lacroix.

The "Illustrated London News," Nov. 8, speaking of Benson's Watches in the Exhibition says—"Ranged around the base of the clock were the Watches which Mr. Benson exhibited, and which have been universally admired for the beauty and elegance of the designs engraved upon them. The movements are of the finest quality which the art of horology is at present capable of producing." Chronometer, duplex, lever, horizontal, repeaters, centre seconds, keyless, split seconds, and every description of watch, adapted to all climates. Benson's Illustrated Pamphlet on Watches (free by post for two stamps) contains a short history of watch making, with descriptions and prices. It acts as a guide in the purchase of a watch, and enables those who live in Scotland, Ireland, Wales, the colonies, India, or any part of the world, to select a watch, and have it sent free and safe by post. J. W. Benson, Prize Medallist, 33 and 34, Ludgate-hill, London. Established 1749.—[Advt.]

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, JANUARY 30, 1863.

MR. E. J. REED.

WE are sure our readers will be glad to hear that Mr. E. J. Reed has been appointed Chief Constructor of the Royal Navy. This appointment reflects as much credit on the Lords of the Admiralty as it does on Mr. Reed. Mr. Reed is pre-eminently a self-made man. Without possessing the advantages of birth, connection, or wealth, he has, in a very few years, purely by his own ability, industry, and integrity, gathered around him friends, inspired confidence in men of reputation and authority, and won a position which is too frequently only obtained by the labours of a life. The principal events of Mr. Reed's career are too well known to our readers to be enlarged on here. He was honourably connected with this Journal as editor for eight years. About three years since he was mainly instrumental in establishing the Institute of Naval Architects, which has already rendered signal service to ship building. Since then he was appointed by the Admiralty to superintend the construction of the "Enterprise," "Favourite," and other vessels of his own design. Having succeeded so well in everything he has undertaken, we were not surprised at his appointment as Chief Constructor of the Navy. It is not often that so young a man as Mr. Reed is called on to perform the duties of so responsible an office. The most deserving men among us have too frequently to wait many long and weary years before they are appreciated as they should be, or rewarded as they deserve. They are obliged to waste the best part of their lives in obscurity or neglect. Somehow or other our authorities, who are almost all old men themselves, have a decided partiality to old men to fill important positions. Preference is too often given to seniority at the expense of merit, and influence and connection usurp the claims of worth. This too general rule has been reversed in Mr. Reed's appointment. Being young, it is in his power to give the department which he superintends the best energies of his life. Mr. Reed is not, as the Emperor of the French said of a popular Prime Minister of this country, "animated with the prejudices of a past age." He is not wedded to any antiquated theory or system; and if he is wise he will not commit himself to any particular principle either in the material or the mode of constructing ships. We are necessarily in a transition state. What was best two years since may not be best now, and what is best now, may not be best two years hence. We cannot fix any boundary to the possibilities of science. The mind of inventors and men of thought being, at the present time, on the stretch for new ideas and plans and principles; and changes and modifications succeed each other so rapidly, that we believe him to be the wisest to superintend any important work, who is ready to listen to all legitimate proposals, and who spreads his sails to catch the most favourable breeze for the national advantage. We have repeatedly stated that we considered it a mistake to appoint such a man as Sir William Armstrong, an inventor and *quasi* manufacturer and contractor, and a man necessarily interested in promoting his own invention at the expense of others, as engineer of rifled artillery. Every man must be more or less prejudiced in favour of his own offspring, even if his intentions be good. And when a man with a favourite system, a fixed idea, or a cut and dried policy, is appointed to a position of trust and responsibility in the army or navy, at such a time as this, when the applied sciences are absolutely revolutionizing our modes and materials of warfare, the public service may be neglected for the sake of a prejudice, or from individual interest. Mr. Reed not being an inventor, cannot be charged with neglecting other inventions for the sake of his own; and we hope, and are inclined to believe, whatever may be said to the contrary, that he is not committed to any particular principle in ship-building, but will be ever ready and willing to adopt any principle which he conscientiously believes to be the best. We most heartily congratulate him on his worthily achieved success, and sincerely hope that his future career will be as useful to the public service as his past efforts have been creditable to himself.

THE NORTH-ATLANTIC SEA-BED.[*]

IT is not often that it has fallen to our lot to peruse a work more replete with scientific interest than this contribution to the natural history of the sea; and the Admiralty must certainly be congratulated on having, in one instance at least, put "the right man in the right place." It is questionable, indeed, whether "my Lords" could have made a more fitting selection than that of Dr. Wallich, for the performance of the service, which has eventuated in the publication of the pamphlet under review. That gentleman, in addition to high scientific acquirements, brought to bear upon the task with which he was entrusted in 1860, the advantage of much experience of the kind most required. He had already served in the capacity of naturalist to Sir F. L. M'Clintock's expedition for the survey of the proposed North Atlantic Telegraph route between Great Britain and America, and he had also published a series of instructive "Notes on the Presence of Animal Life at Vast Depths in the Sea."

It was on the 2nd of July, 1860, that Dr. Wallich left Stornaway in the "Bulldog," on what may be justly termed his voyage of discovery in the North Atlantic. The descriptive powers of the Doctor are very satisfactorily revealed in the diary which he constantly kept, and his pictures of scenery and atmospheric phenomena, witnessed or experienced during the progress of the cruise, could scarcely be excelled in vividness and reality. On this account alone, "The North-Atlantic Sea-Bed" would be worthy of attention, but it has far higher claims to public approval, as will presently be seen.

Very early after his departure from Stornaway, the explorer commenced taking soundings, and thus making the ocean's bed tell its own story. On the ninth of July, and at a point about two-thirds of the distance from the Faroes and Iceland, the sounding instrument "brought up, from a depth of 682 fathoms, a piece of quartz rock about an inch square, several fragments of basalt, an old and much worn fragmentary valve of *Pollicipes*, a minute pellet of mud about the size of a pea, a calcareous *Serpula-tube*, about half an inch in length, and evidently just broken off from the stone to which it was attached, inasmuch as the fleshy matter was perfectly fresh at the point of fracture, and, lastly, a minute *spirorbis*, and two shells of *Truncatulina lobata*, still adherent to small stones, and apparently alive." Here were abundant materials for examination, and Dr. Wallich does not lose the opportunity of effecting it. With patience and extreme care each specimen was inspected, and, finally, important conclusions were drawn from their various peculiarities. The principal point established by this and successive soundings in the same vicinity was to the effect that "an offshoot of the Arctic current moves slowly downwards between the Faroe Islands and Iceland." The extreme and sometimes sudden variations in depth demonstrated by the sounding apparatus are not among the least remarkable phenomena of the ocean. "At a distance of 40 miles to the westward we find 64 fathoms, then a plateau of nearly 70 miles diameter, on which the depth varies between 40 and 100 fathoms; and, lastly, another dip of 640 fathoms, which decreases to 445 fathoms at 17 miles distance from the Icelandic coast." Dr. Wallich does not, however, consider that these alternations of level are of sufficient extent to prevent, if need be, the laying across them of a telegraphic cable. Further surveys would, nevertheless, be requisite, in order to gain indications of the valley lines, and to select for its submergence the most favourable course. "Wherever the valleys happen to be narrow and irregular, no matter how slowly a cable may be paid out, festoons would form, the weight of which, acting on the points of contact, would inevitably engender a fatal strain."

It is curious to imagine the process of surveying the "deep bosom of the ocean," as though it were dry land, over which a railway were to be carried, but no doubt exists of its perfect practicability.

The microscope was frequently pressed into the service of the enquirer into the mysteries of the sea, and it often revealed facts upon which to base theories and hinge deductions. In truth, that instrument proved a valuable adjunct to the scientific apparatus.

On the 19th of July the "Bulldog" had approached to within thirty miles of Greenland, and we cannot forbear transcribing the author's impressions on a yet nearer view of that place:—"Before us, stretched in a long line, extending as far on either side as the eye could reach, lay the rugged mountain ranges that hem in the eternal desolation beyond. No gentle slope mingled with the outline of the innumerable icy peaks which stood out against the horizon with an almost terrible distinctness, but everywhere was to be witnessed the stern grandeur of a scene, beside which the snowy ranges of the Himalaya, majestic as they are, would appear subdued into tameness. Between the ridges, the snows of centuries had filled up the chasms, and hid from view all but the most perpendicular faces of rock. No portion of the shore line was visible; yet its position and direction could be determined by the differences in character of the fixed or floating ice. From it, to within a short distance of the ship, extended a dense mass of aggregated pack ice, out of the midst of which at intervals huge bergs reared up their glistening sides, whilst floating clear of the pack, detached masses were to be seen, whose battered condition told of many an Arctic blast and wave. . . . The attempt to describe such a scene is vain; the eye may gaze upon it and admire, but the soul, as if conscious of God's presence, bows down in adoration, and is speechless."

The rugged and inhospitable grandeur of

---

[*] The North-Atlantic Sea-Bed: comprising a Diary of the Voyage on board H.M.S "Bulldog," in 1860; and Observations on the Presence of Animal Life, and the Formation and Nature of Organic Deposit at Great Depths in the Ocean. By G. C. Wallich, M.D., F.L.S., F.G.S., &c., &c., &c. Part 1. London: John Van Voorst, Paternoster-row. 1862.

this place may be well imagined from the Doctor's picture of it.

The greatest depth of water between Iceland and Greenland, a distance of some 600 miles, was found, half way accross, to be 1,572 fathoms, the descent down to that point being apparently very regular. "The ascent was equally regular up to a point about fifty miles from the east coast of Greenland. But here a sudden and remarkable rise was met with, the depth decreasing from 806 to 227 fathoms in three and a quarter miles; that is, at the rate of 1,050 ft. per mile!"

Gladly should we accompany our excellent guide and exponent in his further experimentations, but space warns us that we must not linger even in his pleasant and profitable company. His learned and highly interesting discourse as to the "Bathymetrical limits of life in the ocean," and his reasons for arriving at conclusions somewhat at variance with commonly received notions thereon, can only be commended to the notice of our readers, should they haply meet with the book in which they appear.

Never before has such a flood of light been poured into the depths of the sea, nor so much information been given of the deepest located of its inhabitants. It is, therefore, impossible to rate too highly the publication which introduces to the public Dr. Wallich's tidings from the "North-Atlantic Sea-Bed."

THE PREVENTION OF ACCIDENTS IN MINES.

The frequent occurrence of appalling accidents in mines and coal-pits tends to cast discredit, not only upon those who are entrusted with their practical management, but upon scientific and mechanical men generally. Scarcely a week passes without the public being shocked by the perusal, in our journals, of the details of some disaster more or less fatal in its consequences in the collieries and mines of this country. It may be said that many of these casualties are unavoidable, and contingent upon the exceptional nature of the operations in the performance of which they occur. To this statement we cannot, however, lend our sanction. We believe that in a great majority of cases—even with the existing arrangements—such fearful catastrophes as those, with which we have lately become familiar, might have been prevented. Too often has it happened that inquests and inquiries have evolved the fact that the exercise of a little more foresight and care would have obviated the necessity of such inquests and inquiries, and have saved many valuable lives. It cannot be denied, nevertheless, that the means of working mines generally, and especially the mechanical adjuncts employed therein, are defective. There is too much haphazard, and not enough system, in the conduct of mining work, as a rule. Those, therefore, of our ingenious mechanics and engineers who are disposed to turn their attention to the solution of the problem, "How to prevent accidents in mines," are deserving of all encouragement and will find a wide field opened up for the exercise of their skill.

Strongly impressed ourselves with the vast and vital importance of the subject, we are determined to promote in every possible way all reasonable projects for the accomplishment of the great object sought, namely, the minimizing of mining accidents. It has, indeed, become almost a national question, and it is one which must, sooner or later, be solved satisfactorily.

Under the influence of these feelings, we this week direct the attention of our readers to a comprehensive plan for the prevention of accidents, illustrations of which are to be found on another page, and which has been forwarded to us by Mr. James Rae, of the Greenwich Iron Ship Building-yard. That gentleman has, ever since the occurrence of the dreadful accident at the Hartley Colliery, about twelve months ago, devoted much time and attention to a consideration of the most effectual means for saving life in mines. He has endeavoured, by a careful examination into the varied causes of past disasters, to devise means for preventing future ones. It will be for the mining authorities and the public to judge in how far he has been successful in his praiseworthy task. Mr. Rae modestly guards himself against claiming the merit of complete originality for every point connected with his scheme, but he has not, in a single instance, servilely borrowed an idea from the work of any predecessor in the same path. Our engraver has rendered justice to the admirable drawings furnished by Mr. Rae, and, consequently, the illustrations almost tell their own story. *(See page. 68.)*

Fig. 1 is a sectional elevation of main shaft, with an iron pipe on either side. These pipes are intended to serve a variety of purposes. Exteriorly they are designed to form guides for the cage or carriage in its ascent and descent; they are also furnished with ratchet teeth, which, in conjunction with an apparatus attached to the cage itself, will effectually prevent the fall of the latter, in case of a breaking rope. The pipes are also intended to serve for the ventilation of the mine by allowing of the pumping out of the gases and foul air, fresh air rushing down the main shaft to supply their place. One of the most important parts played by these universal tubes remains to be told. In cases of emergency they become safety ladders for the escape of the miners!

A loaded coal waggon is shown resting upon palls locked in the ratchet teeth, as would be the case if the lifting rope had broken.

Fig. 2 is another sectional view, representing the front of the ratchet guide, and the side of the exhaust fan.

Fig. 3 is a sectional plan of main shaft through the exhaust pipes and pump.

Fig. 4 comprises a plan of main shaft with the two *blasts* or exhaust fans, for these may be used for sucking or blowing.

Fig. 5 is a cross section of main shaft.

Fig. 6 side elevation of fans.

Fig. 7 is a vertical section, showing one of the pipes in the act of being used as an escape ladder. The existence of such contrivances as these at the Hartley colliery would have enabled every imprisoned man and boy to have emerged from his living tomb.

A, Represents loaded coal waggon.
B, Escape door at bottom of pipe.
C, Escape door at top of pipe.
D, Front elevation of disconnecting hook.
E, Entrance to pit at the foot of shaft.
F, Ladders by which to enter escape pipes.
G, Exhaust pipes under ground.

By a careful inspection of the accompanying engravings, it will, we think, be seen that the inventor of this new mode of preventing accidents has had an eye to every probable, if not to every possible, cause of such deplorable events as have been referred to. Whilst suggesting the adoption of his entire plan, wherever practicable, Mr. Rae proposes also improvements in existing arrangements. He would, for example, recommend that in all cases the vertical shafts of pits and mines should be lined with cast iron, the lining to be put together in segments, connected by bolts and nuts. The joints should be caulked with cement. The segments should be cast of suitable lengths, and provided with flanges for uniting them horizontally and vertically. A curb of this kind might be carried to any depth, and made perfectly water-tight. Once properly constructed, it would last for any length of time. Curbs formed of wood, on the contrary, are continually decaying and becoming leaky, no matter how well fitted in the first instance. Iron curbs, therefore, says Mr. Rae, will be found not only more durable, but in the end cheaper than wooden ones. In this conclusion most persons who have had any experience in the matter will feel disposed, as we do, to join. Moreover, the substitution of iron for wood, would have the advantage of paving the way for the introduction of escape tubes, which certainly have much to recommend them, and do away altogether with the necessity for the much talked of "second shaft."

In reference to the means of preventing the fall of the cage when its suspending rope has broken, he remarks that the guides might be "either cast on the pipes, or be bolted to them, being in either case placed perfectly true. The faces of the guides should both be cast with teeth upon them in the usual form of the ratchet, and be of about 4 in. pitch and 12 in. broad. The permanent hoist carriage should be made of wrought iron, with guide blocks fitted on either side to fit the vertical guides on the tubes. The guide blocks might be furnished with friction rollers, so as to reduce friction in ascent or descent to a minimum. On the under side of the carriage there should be fitted two catches or palls, working in slots or grooves. The palls would be kept out of gear, so as to allow the free motion upwards or downwards of the carriage, but by the arrangement I propose they would be relieved the instant the hoist rope or chain broke, and locking themselves in the teeth of the vertical ratchet, would suspend the carriage until it was again made fast to the repaired or replaced rope."

The arrangement by which this important object is proposed to be effected is, we must say, exceedingly ingenious, and yet so simple that its failure in action seems to us to be impossible. The palls are acted upon by powerful springs, which come into play self-actingly on the occurrence of such an accident as that named, and once adjusted will not require even looking at, much less repairing, for years.

A disengaging hook for preventing the "overwinding" of the cage, as it is termed by miners, forms another feature in Mr. Rae's plans for saving life, and an excellent feature it is. It is well known that hundreds, if not thousands, of lives have been sacrificed from this unfortunate cause. Too often the engine-driver has been at fault; but Mr. Rae's disengaging hook is a perfect safeguard against carelessness in this direction. The instant the cage has reached its proper height, the hook detaches itself from the carriage, and the latter, with the men or material within it, remains stationary at the mouth of the pit.

We have endeavoured to give a general outline of the whole of the arrangements proposed by Mr. Rae; but, of course, there are many points of detail into which we cannot at present go. For the information of those of our readers who may take especial interest in the subject, we may state further that a model of a coal pit, fitted with all the appurtenances named above, has been constructed by the talented gentleman in question, and that it may be seen on application at the office of the MECHANICS' MAGAZINE.

The ventilating process, as projected in this instance, does seem to us, moreover, to entitle its inventor to the consideration of the Nationa

Association for the Relief of British Miners, who some time since offered a premium of 200 guineas "to any engineer or other person who projects and carries into effect the best and most effective plan for the perfect ventilation of mines." It is decidedly our opinion that no better "plan" exists, at present, for the ventilation of mines than that proposed by Mr. James Rae. We shall be glad, therefore, if the association give him the opportunity of demonstrating, with more minute detail than it is possible here to give, the merits and peculiarities of his mode of saving life in mines.

FORTIFICATION.

Treatise on Fortification; or, Lectures delivered to Officers Reading for the Staff. By Capt. LENDY, F.G.S., F.L.S., &c., Director of the Practical Military College of Sunbury. W. Mitchell: Charing-cross, London.

THE military direction which the public mind has of late taken, has rendered a knowledge of the general principles on which the art of war is practised almost essential to a polite education. The daily papers teem with articles "horribly stuffed with epithets of war," which are unintelligible to most readers, yet under these terms some eight millions of money will have been spent within the next few years, and that is sufficient justification of the curiosity to know what permanent forms this gigantic expenditure is to assume. Were it practicable to write a popular handbook to the whole art of war, it would be just now a most useful publication; and, if the present state of things continues, it would grow into an indispensable *vade mecum* to the breakfast table, or a young lady's pocket companion. Though it is too much to expect that a science like that of military engineering should be made plain to the commonest understanding, as some empirics pretend to do, it must certainly be desirable that the means to the acquirement of a knowledge of it should be made as easy as possible. And it is the great merit of Capt. Lendy's lectures that, although they are addressed to military men, who have a previous knowledge of the subject, they are so distinct and clear that a man of ordinary mathematical attainments can easily master the art of fortification all the more easily if the author had embodied in his work a table of definitions, as in Major Straith's treatise; for we labour under this disadvantage, that nearly all the terms are borrowed from the French, and that their significations are often forced and unnatural.

Since the days of Vauban, fortification has always lagged behind. The means of defence have never equalled the means of attack, so that the idea of an impregnable fortress has become obliterated, and a city or position is fortified, not in the expectation of preventing it from ever being taken, but simply with a view to delay its capture to the latest possible period, and until time has been afforded for relief to arrive to compel the enemy to raise the siege. If this axiom be borne in mind, it will be seen that, although a fortified post enables a small force to resist a a numerous foe, yet an army, able to compete with the foe on equal terms, is required to prevent the post from ultimately falling into the enemy's hands. Consequently, the costly and extensive works now in the course of erection to protect our naval yards and arsenals will not render them impregnable, nor relieve us from the expense of maintaining a single soldier the less. The utmost the works will do will be to protect the yards from a *coup-de-main*, and allow time for the army to meet the foe. Nor must it be fancied that iron clad forts will be secure from attack, for besiegers do not rely upon artillery fire alone to overcome resistance. They have, in addition, two formidable weapons—mines and blockade—and, moreover, their fire is converging while that of the besieged is diverging; so that the relation between the means of defence and attack remain as it has been since Vauban; and the utmost fortifications can do is to create delay. This does not mean that fortifications will not preserve the position from capture; but in cases where they do so, it will be fonnd that the enemy's defeat arises either from the exhaustion of his force or the failure of his supplies, or interruption of his communication, or from the advance of an overpowering relieving force. At the time the fortified *enceinte* of Paris was discussed and decided upon, it was never suggested by the most urgent advocates of the proposition, that it would, of itself, prevent the city from being captured, but simply that it would allow the garrison and National Guard (as inferior troops fighting under cover) to hold out during 30 days, which would be time sufficient to allow an army to assemble behind the Loire and to march to the relief of the capital.

Military engineering, like ship-building, is, we think, reduced to a state of transition, consequent upon the immense development of the means of attack, due to the introduction of rifled artillery and fire arms; yet both here and on the continent, we fancy old measurements and dimensions are retained. Engineers formerly laid down the maximum length of the lines of defence at 250 yards, which, being greater than the range of musketry, lead to the employment of wall pieces. But as the Enfield has now an effective range of 900 yards, whereas the old musket could not be relied upon beyond 180 yards, it may be very fairly presumed that the length of the lines of defence may be increased without diminishing their value. Capt. Lendy admits they may be increased to 300 yards, and that some engineers have proposed an extension to 500 yards, but he doubts if a soldier can see a man in the trenches at that distance. The increase of 50 yards upon the whole length is very slight, and does not at all correspond with the increase of range obtained. When the lines of defence are made longer, the front will also be increased in length, and the number of salients, and therefore of points of attack, will be the fewer. There would, consequently, be less labour and time—both of which mean money—expended on the defence, were it not that the works will require to be made much stouter to resist the augmented range and penetrating effect of the enemy's artillery. And they will require to be more frequently provided with cover for the artillery. On the other hand, the attacking force will have to commence operations at a greater distance than hitherto, which has been 600 yards for the first parallel. With the present range, besiegers could not remain at this distance without cover, nor probably at anything under 1,000 yards in ordinary cases, and where the nature of the ground is not adverse. The approaches, therefore, will be more laborious and more tedious, and he will be the longer kept under fire, so much so that Capt. Lendy is inclined to believe sapping will be abandoned in favour of mining.

It is very satisfactory to find so important an authority as the writer unite with D'Arcon in protesting against the "*professional system* which has the effect of spoiling all our ideas," and insisting on the necessity of taking common sense as a guide. D'Arcon had laughed at the men of one idea, who, like the leather-seller in the fable of the besieged town, declared that their particular hobby was all that was necessary for defensive purposes—at the linesman, who would trust solely in infantry; at sailors, who would rely upon ships alone; artillerists on coast batteries; and he surmised that cavalry mounted on hippopotomi might be suggested for defensive manœuvres. And Captain Lendy contends that engineers are equally absurd in imagining that nothing but fortifications are needed to insure the quiet possesion of the country; adding, as becomes a staff-officer, "Amid this variety of opinions nothing seems to have been forgotten, except the indispensable necessity of their *being all united*, and made to concur conjointly towards the same end." In the present day engineers are in the ascendant, and our rulers appear more than ever to rely on walls and earthworks for defence, but they appear to forget that fortified towns and positions, as protection against invasion, are more matters of routine than of demonstrated utility. When the modern system of fortification was introduced, it found the frontiers of continental states protected by triple lines of fortresses. Instead of ascertaining whether the arrangement were wise or not, engineers adopted it, and contented themselves with adapting the works to resist modern artillery. But invading armies now are generally numerous enough to be able to pass between the fortresses, and to neglect the garrisons they can contain, and to prevent them from cutting their lines of communication by detaching a corps of observation. Undoubtedly the great mistake committed by Napoleon in 1814, and that which contributed more than anything else to secure victory to the standards of the allies, was his scattering his troops as garrisons, and shutting them up in Dantzic, Homburg, Glogau, and other fortified towns, instead of concentrating them on the Rhine, the frontier of his empire. The lust of territorial aggrandizement—the very possession of that which Napoleon had fought for—was the immediate cause of his ruin; and he who in his Italian campaign had taught how victory was to be won in spite of fortresses, and in neglect of them, was destined to fall when he reversed the strategy of his youth.

Seeing how frail a barrier are triple lines of the strongest fortresses to the advance of a numerous and disciplined army, led by an enterprising commander, most civilians will be inclined to reply in the affirmative to the question which the author puts, "Whether this enormous outlay on artificial defence is not altogether useless?" He estimates the mean cost of a fortified town at £600,000; and a frontier of 150 miles long would require 21 such strong places. France had, in 1829, 186 fortresses; and Bureau de Pusy declared that, with their annual cost for maintenance alone, an army of 100,000 men could be organized. In 1840, the Thiers' Ministry ordered the fortification of Paris. What the real cost was, no one can tell. It has been variously stated from three and a half to eight millions sterling; and since then most continental States have adopted, as a system, the fortification of the capital, and the erection of a zone of fortresses on the frontier, consisting, sometimes, of as many as four lines. These would be all very well if the invader would sit down before the obstacle provided for him, but that he is not likely to do. Unless he be purblind, he will seek to make his attack on a point which is not prepared to resist, and not run his head against a stone wall, built for the very purpose of cracking his skull. And "let us remember that at present armies are more numerous, and more rapid, in their movements than formerly, and that a fortress has no influence but on the ground, covered by its guns, and *that* it is only when it is a place situated *there*, and *there* only, *where* the enemy must pass, that permanent fortifications are advisable."

In the present transitional state of the means of attack and defence, it does not seem very prudent or economical to expend large sums on fortifications. We are quite willing to make dockyards an exception in deference to the authorities, but among them it is notorious difference of opinion exists as to the proper mode of applying the money; and many think the works at Portsmouth, for instance, unnecessarily large and massive. Rear-Admiral Robinson said no extent of fortification could make it safe from insult; and people point to Paris, which was considered, twenty years ago, to have been made as strong as it was possible to make it with its bastioned *enceinte* and girdle of detached forts; but now it is admitted that rifled artillery would make very short work of the defences of our neighbour's capital, and that, so far as it could offer any effective resistance, it might as well be left open. Beyond the glacis is a zone, called *Rayon de servitude militaire*, on which it is forbidden to erect any permanent construction. The consequence is that, besides the compensation paid in the first instance by the State, the owners of the land are unable to make the most of their property. Increased range has rendered the zone insufficient, and it will have to be extended at farther cost and inconvenience. The forts ought to be pulled down and removed farther off, else, if they and the bastions are ever engaged at the same time, they will run great risk of firing into one another. It may be answered, that, if we are to wait until the means of attack are developed to their full extent, we should never begin, and that we should therefore be liable to be surprised at any time; but what has been said with reference to continental lines of fortresses, is equally applicable to maritime frontiers, namely—that the foe will not always pass where you are prepared to resist him. Our chief line of defence is assuredly the navy, but it is quite within range of probabilities that it may be broken by storm, or forced, or eluded. In that case the foe would seek either to reduce our naval strength by destroying the yards, or to subjugate the kingdom by taking possession of the capital. The latter no amount of fortification on the maritime frontier could preserve, if the invader were in sufficient force, as he undoubtedly would be, and therefore it is foolish to speak of the works at Portsmouth as though they were capable of arresting a hostile advance upon London—as though they were outworks of the capital. The only ground on which they can be justified is as protection to our naval resources. Works may be also required to afford protection to commercial harbours and anchorages, but anything like the system of martello towers is absolute folly. Making common sense his guide, rising above professional routine, and disdaining slavish obedience to continental examples, Captain Lendy says, that "the capital should be made secure against surprise, famine, and bombardment (by no means easy when its population is counted by millions), but that the defence of the territory should be entrusted to active forces—the army." A good system of signals, which the electric telegraph supplies; roads parallel to the coast, which we have, in addition to the coast railways, that would allow what the Duke of Wellington said would enable him to defend the Isle against the world in arms—the defenders to move rapidly, and mass overpowering forces on the flank of the foe; a well-disciplined and moveable army, and a properly-organized reserve, all of which we possess in the Army, Militia, and Volunteers; and "Field fortification, well understood, will make up for inferiority of numbers in almost every circumstance of war."

GOVERNMENT ENGINEERS AFLOAT AND ASHORE.

Under the above heading an article appeared in the Mechanics' Magazine of the 2nd inst. It reflected with some severity upon the appointment of Mr. Bannister as Assistant Engineer of Woolwich Dockyard, on the ground of that gentleman's alleged deficiency of practical engineering experience. It is only fair to Mr. Bannister to say, that since the publication of the article in question, we have seen several testimonials as to his ability as an engineer, and which induce us to think differently of his qualification for the post he holds. We retract nothing, however, of our strictures upon an Examination system, which tends to elevate the mere mathematician and theorist above the practical man.

Literature.

Treatise on the Mathematical Theory of the Steam Engine; with Rules at length and Examples worked out for Practical Men. By T. Baker, C.E., Author of "Statics and Dynamics," &c., &c., &c. London: Virtue Brothers and Co., 26, Ivy-lane, Paternoster-row.

This little volume, forming No. 139 of the series of Rudimentary Scientific works, the publication of which, originally commenced by the late Mr. Weale, is now carried on by Virtue Brothers, has some claims to the notice of "practical men." We question, nevertheless, its ever being very extensively consulted by them. There are marks of haste, not to say, carelessness, in its compilation, which must tend to lessen its value considerably, and besides, it is not precisely what it professes to be. To those who are yet in their student days it may be of some service as an introduction to the study of more important and abstruse volumes, and this is the highest praise we can conscientiously accord to it.

One does not usually look for fine writing, or what is termed "flowery" language, in mathematical treatises, but these have been attempted in the work before us. With what success our readers shall judge. After describing the "simple operations" which produce motion in the locomotive engine, and which description is rather suited to the school-room than the workshop, Mr. Baker delivers himself as follows:—"Such is the modern locomotive engine—an illustrative example of the genius of man; but, like other important inventions, it is the joint production of many minds, and many more are directed to its further improvements. The records of the Patent Office show that from January, 1840, to the end of September, 1849, no less than 226 patents were enrolled, all of them more or less applicable to the steam-engine and its appendages. Of these 226 patents, 45 were enrolled during the first nine months of 1849. It has been remarked that steam-engines and railways were too matter-of-fact subjects for poets and painters, but, from the above record, it is evident that they deeply impress themselves upon the inventive intellect of the world; and if the prodigies performed by steam remain unsung, or unportrayed, they dare, if not realise, the very sublimity of both poetry and painting; for what scene is more interesting to delineate than one of these stately machines moving safely along, at eagle speed, the very *élite* of the land, including even royalty itself (!) through districts rich in historical associations of past ages, and at the same time teeming with the great works of Nature and Art (!) Surely it cannot be that the subject is too lofty a one for poetical or pictorial illustration, for in greatness of idea lies the success of both." Thank Providence, the end of the sentence is at last reached, and we hope never to meet with such another ungrammatical agglomeration of the sublime and the nonsensical as is involved in it—at least, not in the pages of a scientific volume. Mr. Baker will do well to confine himself in future to figures arithmetical, and not to attempt those of speech. A new method of showing the positions of slide-valves by geometrical construction, and for which the author acknowledges himself indebted to C. E. Amos, Esq., of the well-known firm of Easton, Amos, and Sons, is given in the treatise, and this has much practical value undoubtedly—for the rest—but possibly, enough has been already said about that.

Solutions of Questions in Arithmetic by First Principles: comprising a Classified Series of Examples in Proportion, Interest, Discount, Stocks, Profit and Loss, Partnership, &c., &c. By Walter McLeod, F.R.G.S., M.C.P., Head-master, Model School, and Master of Method, Royal Military Hospital, Chelsea. London: Longman and Co.

Long before the publication of this work, Mr. McLeod had established for himself a well-earned reputation as an arithmetical authority. That reputation will be enhanced considerably by his little volume of "solutions." It is precisely the book which was wanted in public and private schools, and, for the sake of pupils in both, we trust that it may be extensively adopted therein.

The author boldly leaves the beaten track of ancient and parrot-like routine, and takes another, and far better course. He not only demonstrates the mode by which arithmetical questions should be worked out, but gives the reasons why they should be so worked. In nearly all our existing text books in arithmetic, examples such as those solved in this manual are worked by statement, according to certain rules which the pupil must learn by heart, before he attempts the solution of a question.

The method adopted by Mr. McLeod, on the contrary, dispenses with rules altogether, and multiplication and division are the only agents used, besides intelligible explanation. It is evident that by such processes the scholar will become something more than a merely mechanical cipherer. He will understand what he is doing, and thus rise to the position of an intelligent agent.

As a sample of Mr. McLeod's explanatory method, we append his definition of bank discount:—"A note or bill is said to be discounted when a bank receives it, and pays to the holder what remains after deducting from the note or bill the legal interest upon it until it becomes due. The interest which is deducted from the note or bill is termed the bank discount. The bank discount, therefore, is the simple interest of the bill paid in advance. Thus, let a bill be drawn for £105 and have a year to run, and let it be discounted at five per cent. The true present worth should be £100, because this sum, bearing interest at five per cent., will, at the end of a year, be worth £105; but the discount deducted for cashing such a bill is £5 5s.; its present worth, therefore, is only £99 15s., which is five shillings less than the true present worth, so that the holder of the bill loses, and the banker gains, the loss being *the interest upon the true discount.*"

Mr. McLeod draws questions from the works of other eminent arithmeticians, as Colenso, Page, and Calder, and solves them in his own admirable manner. As a whole, the work is indeed excellent, and we but perform a simple duty in cordially recommending it to the public.

ON THE RELATIONS OF DEATH TO LIFE IN NATURE

BY J. D. DANA.

1. THE creation of a plant with "seed in itself," as Moses states in his concise description, was the simultaneous institution of life and death. It was the establishment of an in-coming and out-going stream, to be in constant flow as long as the kingdoms of life should last—an incessant renewal of youth, and rejection of age.

All life is a system of progressing changes in cycles—the germ first, then the embryo, the young, the adult, and last, the seed or germ again, to continue the rounds; the adult sooner or later disappearing from the field of progress, and then from the sphere of existence. Death is implied in the very inception of the scheme.

2. Death is also in every step of the process of life. For the living being is throwing off effete matter during all its growth; the change is constant, so that with each year a large part of the material in our bodies has passed away and been replaced by new. Moreover, the force which had been expended in making a cell, or particle of tissue, goes to form a new cell or particle when the former dies, and was needed for the new formation going on. Force is not lost or wasted, but used again. There is unceasing flow, and in this flow is life; its cessation is death.

3. The kingdom of plants was instituted to turn mineral matter into organic, that the higher kingdom of animals might thereby have the means of sustenance; for no animal can live on mineral matter. Now this living of animals on plants implies the death of plants.

Again, the rocks of the globe are, to a great extent, made of the remains of dead animals.

4. The chemistry of life, also, required death. Life in the plant or animal, if sustained by means of nutriment, and continued consuming, with no compensating system, would evidently end in an exhaustion of any finite supply. A perfect adjustment was therefore necessary, by which nutriment should sustain life, and life contribute to nutriment. Now, the plant takes up carbonic acid from the atmosphere, appropriates the carbon, and gives back the oxygen. Yet there is no tendency to an exhaustion of the atmospheric carbonic acid, or an over supply of the oxygen; for death strikes an exact balance.

The death of the plant ends in a change of all its carbon into carbonic acid again. Thus the plant, as it grows, decomposes carbonic acid to get carbon, and then ends in making, by its decay, as much carbonic acid, and restoring it to the atmosphere. Thus, through death, the compensation is perfect. The atmosphere loses only what it receives. Again, as just now observed, the plant, in growing, gives oxygen to the atmosphere; but in the decay of the plant, the carbonic acid formed is made by taking up the same amount of oxygen. The same carbon that lost oxygen when becoming a part of the plant, takes it again at the decay. The system is hence complete. The parts play into one another in perpetual interchange. Take death and decay out of the system, and it would not work.*

Animal life, as above stated, was made to subsist on plants. But the scheme is so well managed as not to disturb the balance made by the vegetable kingdom alone. For all the carbon of animals comes from plants. The plants which feed an animal, and which, on decay, would have turned into carbonic acid, become changed into carbonic acid in the course of the growth of the animal, so that the whole amount of carbonic acid which the animal makes, is only what the plants would have made if left to natural decay. Thus the higher kingdom of life is introduced and sustained, and yet the balance remains undisturbed. The system is perfect.

5. Again, one part of the animal kingdom, through every class, is made to eat up the other part, or at least live on it. The flesh-eaters are of all grades, low and high, from the infusorium and maggot, to the lion and man. Some take what is already dead, or decomposing; others kill and eat. On this subject we observe:—

(1.) Death is in the system of nature—death from earthquake, lightning, and all moving forces, as well as by natural decay; and the creation of carnivorous animals was hence in harmony with the system.

(2.) Various noxious animals are held in check by the carnivorous species.

(3.) By means of flesh-eaters, the diversity of animal species subsisting on a given amount of vegetation is vastly increased, and a wider expansion is given to the animal kingdom.

(4.) Putrefaction of the dead is prevented by a multitude of scavengers, who, at the same time, turn the flesh into food for the vegetable kingdom; and thus plants feed animals, and animals feed plants—one of Nature's circles again.

The last two principles mentioned are of profound importance. The vegetable kingdom is a provision for the storing away or magazining of force for the animal kingdom. This force is acquired through the sun's influence or forces acting on the plant, and so promoting growth; mineral matter is thereby carried up to a higher grade of composition, that of starch, vegetable fibre and sugar, and this is a state of concentrated or accumulated force. To this stored force animals go, in order to carry forward their development; and, moreover, the grade of composition thus rises still higher, to muscle and nerve (which contain nitrogen in addition to the constituents of the plant), and this is a magazining of force in a still more concentrated or condensed state. There are thus five states of stored force in nature—three in the *inorganic*, the solid, liquid, and gaseous; and two in the *organic*, the vegetable and animal.

Now what is the provision to meet this last and highest condition? Is this magazined force left to go wholly to waste by the death and decomposition of the plant-eaters? Just the contrary: an extensive system of flesh-eaters was instituted which should live upon it, and continue it in action in sustaining animal life among successive tribes. The flow is taken at its height, and the power is employed again and again, and made gradually to ebb. What is left as the refuse is inorganic matter—the excremented carbonic acid, water, and excrements, with bones or any stony secretions present. Thus the flow starts at the inorganic kingdom, and returns again to the inorganic. Moreover, in the class of quadrupeds (mammals), the flesh of the herbivores (cattle) is among the means by which the animal type is borne to the higher grade of the carnivores. The true carnivores, besides, take the best of meat. Whales may live on the inferior animals of the sea; but the large forest flesh-eaters take beef and the like.

There is another admirable point in this scheme. The death and decomposition of plant-eaters would have rendered the waters and air, locally at least, destructive to life. It is well known that it is necessary in an aquarium to have flesh-eaters along with the plant-eaters and plants. And when in this way the living species are well balanced, the water will remain pure, and the animals live on indefinitely. If not so balanced, if an animal is left to decay, the waters become foul, and often everything dies. Putrefaction and noxious chemical combinations follow death, because, in life, the constituents, carbon, hydrogen, nitrogen, and oxygen, are in a constrained state, at the furthest remove from what chemical forces alone can produce; and hence, when the restraint is taken off at death, the elements fly into new conditions, according to their affinities. Now animals, dying yearly by myriads, are met at death by an arrangement which makes the dead contribute anew to animal life as its aliment, and in this very process the flesh ultimately comes out innocuous, and is at last so far changed to the inorganic condition as to be the best of fertilizers for plants. Part of the process of getting rid of the great fleshy carcases consists in their minute subdivision by the feeding of larves of insects, and, furthur, an infinitesimal division of the insect as the food of the infusoria,—which again may become the nutriment of larger animals, to go the rounds once more. But the final result is, as stated, *plant-food*—largely through the processes of digestion and excretion, but part through the decomposition of animals that are too small and readily dried up to prove offensive.

Thus the carnivorons tribes were necessary to make the system of life perfect.

One word respecting the necessity of a check on the excessive multiplication of individuals. Nature, as just now observed, is a system of constantly varying conditions—of changing seasons, winds, clouds: of inconstancy, under law, in all forces and circumstances. At the same time, the growth of a species requires the nicest adjustment of special conditions in each case. On this account the reproductive powers in species is, in many cases, excessively large, so that the various accidents to which the eggs or young would be exposed, might not cause their extermination. This provision opened the way for occasional excessive multiplication, and required a check from carnivorous races.

6. Finally, could death be prevented in a system of living beings in nature without a constant miracle? How should the earth be managed to secure it against death? It would be necessary to still the waves, for they are throwing animals and plants on the coast to die; to still the winds, for they are ever destroying in some parts of their course; to still even the streams and rains. With winds and waves, not only helpless animals and plants, but men's houses, ships, and boats, would now and then be destroyed, in spite of prudent precaution and holy living. But if we still the waves, the winds, and the streams, the earth would rot in the stagnation, and here again is death!

We thus learn, that in life the fundamental idea of reproduction implies death; the processes of life are the processes simultaneously of death; the stability of the system of life requires death; the vegetable kingdom is made to feed animals, and the animal kingdom, while containing plant-eaters, demands flesh-eaters for its own balance, for the removal of the dead, and to make out of dead flesh the proper food for plants, thus to pay its debt to the vegetable kingdom. Hence death pervades the whole system of life in its essence and physical laws; and it could not be prevented in a world of active forces except by a constant miracle; and this would be an annihilation of nature, that is, a system of law.—*Silliman's Journal of Science and Arts.*

THE LATE MR. RICHARD GREEN.

LESS than twelve months ago the shipping interest lost a valued friend in the person of the late Mr. Dunbar. It is now our painful duty to announce the decease of the eminent shipowner and builder, Mr. Richard Green, which took place at the residence of his sister, in Regent's-park, on the 17th inst., he having just completed his 59th year.

Mr. Green was the owner of a magnificent fleet of more than 30 ships, none of which is less than 1,000 tons, trading to India, China, and Australia. He employed, on the average, 600 artificers and labourers in his dockyards, and more than 1,200 officers and seamen afloat.

As a shipbuilder Mr. Green was averse to innovation. He never could be persuaded to construct iron vessels, although the last two launched by him—the "Renown," and "Shannon," respectively of 1,450 tons—were furnished with iron beams or girders. Perhaps this resolution was the result of the failure of the screw as an auxiliary, which he, many years ago, adopted in the "Vernon" and "Earl of Hardwick;" but subsequently abandoned, partly in consequence of the space taken up by the machinery and fuel, and partly by the damage the vibration caused to the cargo.

---

* In early geological history, as is generally believed among geologists, there was an excess of carbonic acid in the atmosphere; and this excess was removed to a great extent by the growth of plants during the carboniferous era. Vegetable material decaying under water does not undergo complete decomposition, and thus part of the carbon is left behind; and so far as there is carbon left, there is an actual abstraction of carbonic acid from the atmosphere by the process of growth. The coal era was a period of great marshes; and by this means the needed purification of the atmosphere was effected, preparing it for land life. The amount abstracted now by the same means is very small, and may be balanced by the carbonic acid from mineral sources and volcanoes.

Mr. Green identified himself closely with the Naval Reserve, and took unwearied interest in its formation and efficiency. He instructed his own officers and men to enrol themselves in the force, and, such was the influence he exerted, that most of his officers hold commissions in that important auxiliary to our maritime power. One of his last acts was a petition to the Board of Admiralty for the permission of merchant ships, where the captain is a lieutenant, the mate a sub-lieutenant, and one fourth of the crew are men of the Royal Naval Reserve, to fly the blue ensign. This petition was before the board when Mr. Green's death took place, and the Duke of Somerset, out of respect to the memory of one who took so much interest in the maritime defences of the country, has since granted the request.

Mr. Green did much to elevate the profession of the mercantile marine. All his officers were carefully selected from the educated classes, and his care for seamen is shown by the fact that he, many years ago, purchased "The Sailors' Home" from his father, and has ever since, not only liberally supported it, but taken a most active part in its management. He highly approved of the regulation for the payment of ships and shipping hands under the Merchant Shipping Act, and let part of the "Home" to Government for that purpose.

Mr. Green was treasurer to the Merchant Seamen's Society, a warm patron of the Poplar Hospital, a zealous supporter of the "Dreadnought" hospital ship, and was chairman of the Training School for the Merchant Navy, conducted on board H.M.S. "Worcester." All these institutions have lost in Mr. Green a wise counsellor, an able advocate, and a liberal benefactor. To the whole of them he has made large bequests, that to the "Dreadnought" being one thousand pounds.

Mr. Green always regarded the interests of seamen as objects of peculiar regard.

Lord Clarence Paget was his intimate friend, and he was frequently solicited to enter the House of Commons in the cause of Liberalism, but his delicate health and multifarious engagements always led him to decline the honour.

His death was the result of general debility—the over-working of mind in a body never robust. He was interred, on the 24th instant, in the grounds of Trinity Church, Poplar, which was built by his father, and was followed to his final resting place by a large concourse of surviving friends, the respect shown being universal throughout the district.

Mr. Green was never married, but it is gratifying to know that so large an establishment will be steadily carried on by his brother, Henry Green, Esq., Captain Toller, formerly in his service, and Captain Wight, who remained in his employ; these three gentlemen being appointed his executors.

EDDINGTON'S PATENT DRAIN PLOUGH.

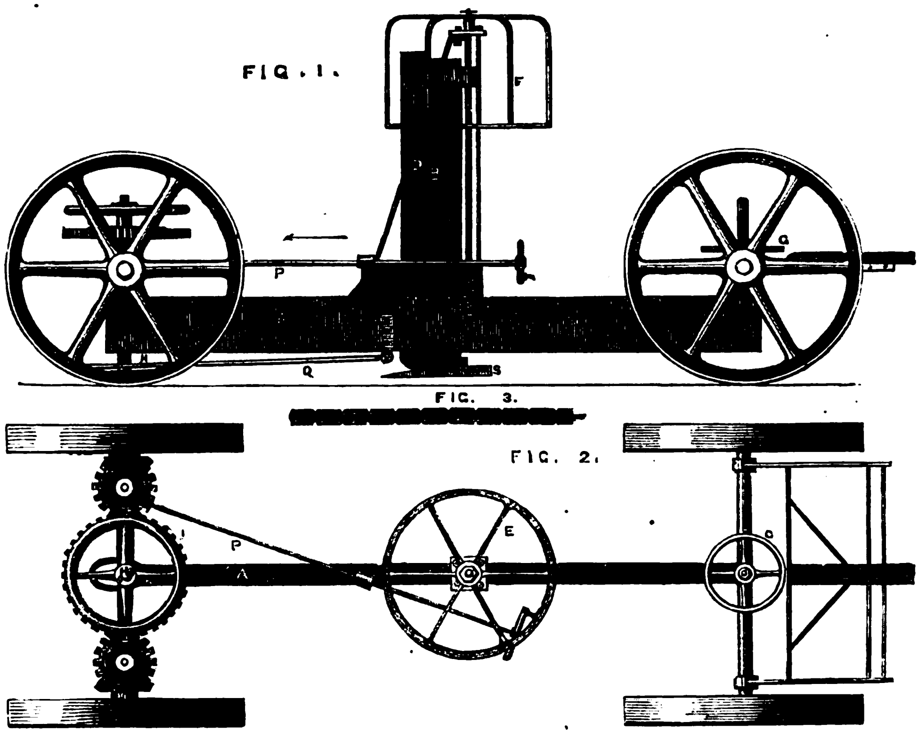

FIG. 1.

FIG. 3.

FIG. 2.

EDDINGTON'S PATENT DRAIN PLOUGH.

A PATENT has been obtained by Mr. W. Eddington, of Chelmsford, for a new plough for draining land. The invention consists in connecting the fore part of a draining plough to the axle by means of a screw and nut, or otherwise, in such manner that the mole can be raised or lowered as the plough travels along, and thereby enabling the drain to be made level, or at a given incline, independently of the unevenness of the surface of the ground, which can be effected by turning a screw or nut by means of a wheel or handle connected therewith. The screw for raising or lowering the fore part of the plough is in communication with the travelling wheels by suitable gearing and clutches, so that the plough and drain may be gradually raised or lowered as it proceeds, whereby to cause a regular fall of the drain on flat lands.

Another part of the invention relates to an improved rope for laying the pipes in the drains made by the ploughs. For this purpose a number of short tubes or sockets of wood are threaded on a small wire or a strong rope, on which the pipes to be laid are strung, which prevents the wear of the rope in passing through the pipes.

Fig 1 of the engravings represent a side elevation; and Fig 2, a plan of a draining plough, fitted and furnished according to this invention.

A A is the beam or frame in which the plough coulter B is fitted, and can be slid up and down for adjustment of depth, being actuated and controlled by a screw, C, supported from the beam A by framework or stays, D D, supporting it at top. The rotation of the screw C, by means of the hand wheel E, operates the nut F, fixed to the coulter B. The rear end of the beam is supported from the hind axle by a screw fixed in the beam passing through the axle, and having on it a hand wheel and nut G, by which it may be raised or lowered, and the position of that end regulated as desired. The fore end is furnished in a similar manner, but in that case the screw H is received in a nut secured to the beam A. On the screw H is fixed a spur wheel I, and hand wheel K, to operate the screw by hand if desired. On the naves of the fore wheels are fixed bevel pinions, taking into other bevel pinions, mounted on studs, fixed to the fore axle; above the latter wheels are spur pinions, geared in with the spur wheel I, fixed in the screw H, at pleasure. P is the steering apparatus, which operates by simply inclining the fore axle in the direction of travelling, as well understood; and Q is the traction bar, to which the traction rope is attached to draw the plough over the ground; S is the mole which forms the passage for the drain or drain tiles, and to which the rope for drawing the tiles is attached.

Fig. 3 represents a portion of a rope, as described under the second head of this invention.

KEELING'S GAS APPARATUS.

A PATENT has been obtained by Mr. J. Keeling, of Reading, for an apparatus for the manufacture of gas. The apparatus consists of an oblong box made of cast iron, or other suitable material, divided into three principal chambers, as illustrated in the annexed engravings; the first, A, fig. 2, serving as a tar cistern; the second, B, a condenser; and the third, C, a purifier. The carbonization of the coal or other gas-making material being effected in the ordinary manner, the hot gas is conveyed by a pipe, D, into the first chamber, where, upon entering an enlarged space, and meeting with the comparatively cold tar, liquor, or water contained in the bottom, the temperature of the gas is considerably lowered, the consequence of which is, that much of its tar and ammoniacal liquor is there deposited. As, however, it is not sufficiently cooled to enter the purifier at once, it passes on by a pipe, E, into the second chamber, B, the upper part of which is subdivided into a number of secondary wedge-shaped compartments communicating with each other, the inlet to each being larger than the outlet, in the proportion of two to one, so that when the gas enters the first compartment it enters freely, but as it makes its exit, the outlet being smaller than the inlet, its passage is retarded; and as this same action occurs every time it passes into a fresh compartment, it is thereby compelled to linger while passing over the cooling surfaces of the condenser and water contained therein, and by this means is made to deposit more completely the remaining tar and ammonia hitherto held in suspension. The peculiar unsteady motion given by the hydraulic main to the gas, and by it transmitted to the water, is here taken advantage of, and assists in the more effectual separation of these impurities. An important feature in these improvements is, that whatever deposit takes place in the condenser, almost the whole of it will fall to the bottom, from whence it may be drawn off at the cock, all chance of the gas way becoming choked up is thus removed.

The manner in which these compartments are constructed will be better understood upon reference to fig. 1, which represents the cover of the first and second chambers, attached to which are a number of plates, G, cast perpendicular to it.

These plates slide into vertical grooves formed in the sides of the second chamber, and by means of cement are made into so many secondary compartments, the form and disposition of which will at once be seen. The gas being sufficiently cooled, now enters by the pipe, H, into the purifier, where it is freed by lime, oxide of iron, or other purifying agent from its sulphuretted hydrogen, carbonic acid, and other impurities. From thence it passes off by the pipe, I, to the gas-holder. In addition to the ordinary water lute for the cover of the purifier, and for the greater security of making gas on shipboard, or other situations in which by the oscillation of the vessel the water might be ejected, it is intended to form the bottom of the cover with a flange, between which and the bottom of the lute an india-rubber packing is to be placed, and the whole secured so as to form a gas-tight joint by means of cross bars and screws. And as oxide of iron is the most suitable material known for the purification of gas manufactured in such situations, from its property of being revivified by communication with the atmosphere, it is proposed to connect a goose-necked pipe with the purifier, through which air may be blown whenever revivification is necessary, such pipe having a cock at bottom, and to be charged with water when not in use. The removal of the cover of the purifier may be thus dispensed with. These modifications, however, are not shown in the engravings, a description being considered sufficient. In order to prevent the accumulation of liquid in the second chamber to an inconvenient height, an overflow pipe is attached thereto, which communicates with the first chamber, into which it descends in the form of a syphon, which, while allowing any superfluous liquid to flow off, is effectually closed against the gas. K is also a syphon, serving as an overflow pipe for tar and ammoniacal liquor; L is an orifice, through which the second chamber is filled with water, and is fitted with a screw plug. Should it be deemed desirable to take out the whole of the ammonia from the gas, sulphuric or other suitable acid may be mixed with the water contained in the middle chamber, but in such case it will be necessary to line the interior with lead or other material capable of resisting the action of the acid.

KEELING'S GAS APPARATUS.

FIG. 2.

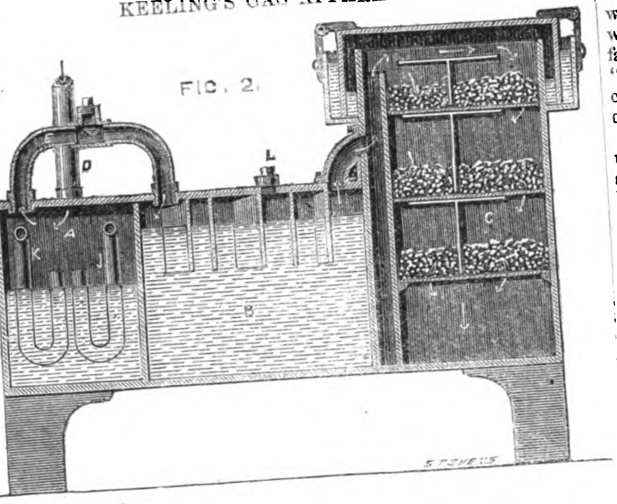

FIG. 1

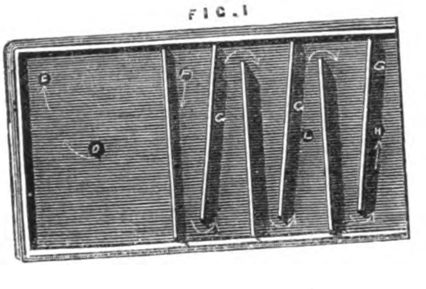
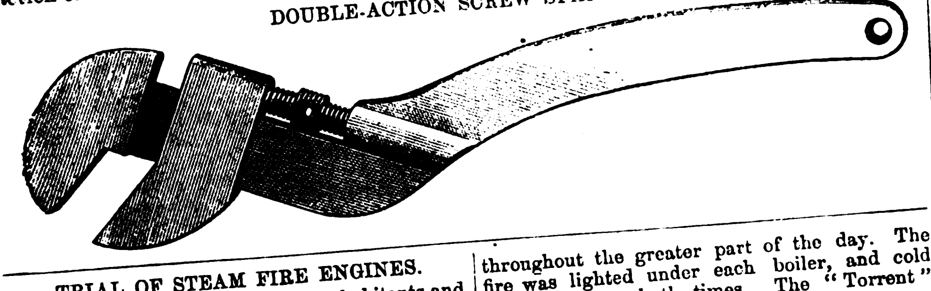


DOUBLE ACTION SCREW SPANNER.

Mr. Thomas Wilson, of Birmingham, has just patented an invention for a new spanner. The superiority of this spanner consists in the novel and rapid mode of its adjustment, by a double action screw, and in its useful and convenient arrangement of curved handle and oblique jaws.

For machinery and jobbing purposes, and particularly for special use in awkward and other situations, it is valuable, its curved handle and oblique jaws giving it, in addition to its other advantages as a moveable spanner, all the facilities of a cranked wrench, which, with its double action screw, can be rapidly adjusted to its work.

DOUBLE-ACTION SCREW SPANNER.



TRIAL OF STEAM FIRE ENGINES.

On Thursday, the 15th inst., the inhabitants and proprietors of the several large manufactories about West Ham, Bow, and Stratford, had an opportunity afforded them by James Kayess, Esq., of the West Ham Abbey Print Works, of seeing the improvements which Messrs. Merryweather and Son have effected in steam fire-engines. Two engines were tried—one, the "Deluge," which was in the International Exhibition, and which, since its return from there, did good service at the large fire near Blackfriars-bridge; the other engine, by the same manufacturers, just completed, and named the "Torrent," is of a class termed "light steam fire-engines." The engines were worked at 9.30 a.m., and again at 3 p.m., and were at work throughout the greater part of the day. The fire was lighted under each boiler, and cold water used at both times. The "Torrent" raised steam to 90 lb. pressure in 12 min. 10 sec., and the "Deluge" 50 lb. of steam in 12 min. 10 sec. Each engine starting to work at those respective pressures. The "Torrent" threw a 1⅛ inch jet well over a chimney 120 ft. high, although the wind was blowing stiff, and afterwards worked on the building, with great force, through 1¾ inch and 1⅞ inch nozzles; from the effective manner in which these jets were delivered, it was very evident that 2⅛ inch jets could be powerfully projected; and 1¼ inch jet was also delivered with very good effect. The "Deluge" threw the water nearly half as high again as the chimney, through a 1¼ inch, then a 1⅜ inch and 1½ inch nozzles; 4¾ inch jets were then attached to the "Deluge," and both engines working at one time, six powerful jets of water were delivered on to various points of the factory. From the manner in which the "Deluge" discharged those jets, it was very evident that 4⅞ inch jets could be projected equally as strong.

Both engines were worked at their steady usual speed, as for fire duty, and the raising of steam was not hurried, so as to show what could be done under ordinary circumstances. Either of these engines can be at work in 9 min. from the time of lighting the fire, if required. The "Torrent" has previously raised steam to a working pressure of 37 lb. per square inch in 8 min.

The pump valves of both engines are specially arranged so as not to choke with foul or gritty water, and so that they cannot get frozen. The working parts bear no undue or transverse strain, and are without fly-wheels. The frames are of wrought iron, and fitted for the roughest travelling without sustaining injury. Among the gentlemen present were:—W. Duncan, Esq., water engineer; Major Greig, head constable; and Mr. Henritt, superintendent of fire police, Liverpool; also Captain Strange, Mr. White, superintendent of the Gravesend police; C. F. Young, Esq., C.E.; Mr. White, of the County Fire Office; Mr. W. Baddeley, &c.

THE NAVY AND THE FRENCH EMPIRE.

Last week we indicated the character of an important letter communication, by Mr. Donald Mc'Kay, on the French Navy. We now give the entire letter, which we extract from the *Boston Commercial Bulletin*. Mr. Mc'Kay is a high authority on naval matters in the United States, and his words are worthy of mature consideration by the authorities of this country. The letter is as follows:—

Paris, Nov. 30, 1862.

Mr. Editor,—I promised you a full report on the state of the French Navy, and having again visited their dockyards and arsenals, I am happy in being able to give it to you. Although I had the Ministerial permission to visit all the dockyards of the Empire, yet I found the greatest difficulty in obtaining the permission of the admirals commanding the different stations, but at last I succeeded.

APPROPRIATIONS.

In the year 1855, a commission, composed of the most able men of each department of the French navy, considered the organisation which it would be proper to give to the Imperial navy, and a report of the Minister of Marine, approved by the Emperor, contains a complete list of the ships composing the French navy, with the strength of each ship in guns and horse power, and no doubt this report is in the hands of our Government.

The same report gives also the number, and strength in guns and horse power, of the ships which are to be built from year to year till 1870. The credits necessary to carry out these plans were voted in 1857, and the plan fixed upon was then to be executed and accomplished in 1867, at each time the French navy was to be composed (besides a large number of ships of inferior classes) of

Screw line of battle ships of first class …………	15
Ditto second class ……	25
Total ………………………………	40

IMPROVEMENTS.

Since then experience has pronounced in favour of iron-cased frigates, and it has been decided by the Imperial Government that the plan fixed upon in 1855 is to be carried out to the letter, with the difference of putting iron-cased frigates instead of line-of-battle ships.

This transformation of the French navy (if war should not accelerate the progress) will be completed in 1870, and the principal fighting parts (for aggressive purposes) of the French fleet will consist at that time in 40 iron-cased frigates of the first class, varying in armament from 36 to 52 guns (all rifled and breech loading), having a horse power of from 900 to 1,200, and all possessing a superior speed, exceeding 12 knots per hour.

Whatever improvements may be made in the meantime in naval architecture, the same plan will be carried out with such slight modifications as well stated and tested experience will show it to be desirable and necessary to adopt, in order to always secure to France the rank of a first naval power.

After all that I have seen, it is my firm conviction that France is the first naval power on the globe, and further, that no other power will possess, at the end of another year, a fleet capable to cope successfully with the French iron-cased fleet on the open sea.

ESTIMATE OF EXPENSES.

The estimate of the French navy expenses, for the year 1863, is as follows :—

	Francs.
SECTION 1.	
Central administration (personnel)	1,059,900
,, ,, (materials)	267,300
Council, general inspection and control	485,777
	1,812,977
SECTION 2.	
Pay of officers and crews	27,335,806
,, marine troops	8,652,810
Different administrations and agencies	5,953,725
Pay of masters, leading men, watchmen	2,766,012
Hospitals	2,254,658
Victuals	13,748,900
	60,411,911
SECTION 3.	
Pay of workmen in the yards	17,000,000
General stores for the fleet	34,954,000
Hydraulic works and civil buildings	8,012,000
Powder	475,412
	60,441,412
SECTION 4.	
Maritime tribunals	147,560
Naval schools and pursers of the navy	210,000
Hydrographic and scientific service	400,000
Purchase of books and cost of printing	489,400
Travelling and different expenses	2,277,660
Temporary expenses	100,000
Convicts	128,000
	3,752,620
SECTION 5.—COLONIES.	
Civil and military service	14,481,600
Materials (civil and military)	3,044,500
Penitentiary service (Guyane)	4,942,800
Local service	2,223,500
	24,692,400
Total of estimated expenses for the navy and the colonies	151,111,320

These estimates have already been found to be not sufficient to cover the probable expenses of the navy in 1863, and therefore an additional grant has been made to cover the expenses. This grant is added to section 3, and allows for

	Francs.
General stores of the fleet	12,500,000
Hydraulic works and civil buildings	4,500,000
	17,000,000

In this additional grant are included for

The purchase of timber	1,500,000
,, ,, iron	3,000,000
For construction of ships in private establishments	2,000,000

The latter items give proof of two facts:—That the French Government continues to give the preference to wooden, and against iron ships, and therefore intends yet to increase its already immense stock of timber; and that the iron-cased ships are to be completed with greater rapidity than was originally contemplated. Therefore the large additional grant for the purchase of iron. I am confirmed in this view by the order given a short time ago, by the Minister of Marine, to complete all the iron-cased ships on the stocks by the middle of next year. With the present relations existing between France and the United States, this fact is of high importance, and looks rather ominous.

To return to the estimate, we find that all the grants for the navy for 1863, deducting those for the colonial service, amount to 143,418,920f., being twenty millions of francs in excess of the Naval Budget for 1860.

The sums allowed for the purchase of the principal materials for naval construction, use will be found in the following table :—

	Francs.
Timber (transportation not included)	6,450,000
Iron and metals of all kinds	10,821,000
Hemp, rope, saileloth, oakum, &c.	2,520,000
Pitch, tar, oil, tallow, soap, &c	2,200,000
Coal and combustibles (transportation not included)	3,100,000
Cloth, woven articles, &c.	250,000
Different articles	325,000
Total for purchase of materials	25,666,000
For purchase of steam engines and all kinds of ready-made stores (from private industry) for naval construction use	10,215,000
Construction and repair of ships in private establishments	4,100,000
Total cost of transportation of material to the naval arsenals	3,710,000
The estimated expenses of the material for the artillery of the navy amount to	2,400,000

The large amounts granted for the purchase of rough material, notwithstanding the immense amount of stores on hand, show the intention of the French Government to be prepared to meet the possible exigencies of suddenly increased armaments.

STEAM NAVY OF FRANCE.

The steam navy of France at the present moment, November, 1862, is composed as follows :—

Class.	Afloat.	Building.	Total.
Line-of-battle ships	36	1	37
Iron-cased frigates	6	10	16
Screw frigates	25	4	29
Paddle ,,	18	—	18
Despatch boats (screw)	35	1	36
,, ,, (paddle)	88	5	93
Iron-plated floating batteries	14	7	21
Gunboats	53	5	58
Transports	34	9	43
Total	325	42	367

SAILING NAVY OF FRANCE.

The sailing navy of France consists at present of:—

Class.	Afloat.	Building.	Total.
Ships of the line	7	—	7
Frigates	23	—	23
Corvettes	12	1	13
Brigs	19	2	21
Small vessels	26	—	26
Transports	32	—	32
Total	119	3	122

STOCK OF MATERIAL ON HAND.

To make it possible for the French Government to carry out the plan for the transformation of the navy, notwithstanding a long war preventing the importation of all kinds of material necessary for the construction of ships, the stock of iron, timber, and coal has been increased by one half over the amounts fixed by the navy regulations to be kept on hand. Thus the stock of timber on hand is sufficient for a 7½ years' consumption; that of masts for a 30 years' ditto; that of small masts for a 10 years' ditto; that of iron for a five years' ditto; that of copper for a five years' ditto; and almost every other article in similar proportion.

It is to be borne in mind that a year's consumption is assumed to be equal to the wants of the navy in the course of its regular development. The last official accounts of the stores on hand are dated January 1, 1861. They are contained in the "Compte général du matériel de la Marine," a work very difficult of access. Since that time the stock has been largely increased, but I will give you the correct amount at that date.

Stock of material on hand in the French Navy yards in January, 1861; also comparison with the stock required to be kept on hand by navy regulations:—

ON HAND JAN. 1, 1861.

The stock of timber, particularly oak, on hand in the French arsenals, is without doubt the finest ever selected. The arsenal of Toulon alone contains upwards of 65,000 tons of the choicest oak timber, mostly procured from the Romagna, the Island of Sardinia, from Burgundy, and the south of France. About 20,000 to 25,000 tons of this quantity are kept in salt water, mixed with fresh, and the remainder is kept in storehouses constructed of solid masonry, and which together have a length of more than a mile and a half. Large as these are they are not sufficient for the wants of the navy, and the whole boundary of the establishment at the Mourillon is being encircled by one building of about a mile in length, intended solely for the storage of timber. This circumstance proves that in France, where the question of iron-cased ships has been very closely studied, the highest authorities of the naval service have come to the conclusion that for sea service the preference has to be given to wooden iron-cased ships, and in general to wood-built ships instead of iron ones.

WOOD VERSUS IRON.

Of the sixteen iron-cased frigates which France possesses afloat and in construction, only two, the "Couronne" (afloat) and the "Heroine" (on the stocks), are built of iron, and it is now regretted by the Government that they were not constructed of wood, for experience has already proved, and without any contradiction, that these vessels, on account of their rapidly fouling bottoms, will not be capable of keeping up in speed with the wooden built and coppered frigates. The "Warrior," of the English fleet, has lost from this cause two knots of her original speed, and it is generally conceded that these iron-built men-of-war ships will have to be taken into dock at least every three months to clean their bottoms. The pirate ship "Alabama" — which by her superior speed defies the whole United States' navy, and which actually keeps up a partial blockade of our Northern ports—is a striking example how the advantages of timber built ships for speed are even recognized in an iron country like England. Well knowing that her safety would lie in her superior speed on a long cruise, Mr. Laird, of Birkenhead, the iron-ship builder, has built this ship expressly of timber, with coppered bottom. I regret to have to state my firm conviction that we do not posses in our navy a single ship which is capable to cope with her in speed. This is the consequence of Government never having trusted to private constructors for the production of superior models for our navy. Vessels of high speed are what we want, but which we never shall possess unless a different course is adopted by our navy department.

The French at the present time have the following iron-cased frigates afloat:—

The "Gloire," "Invincible," and "Normandie," built of timber, and all from the same lines, by Mr. Dupuy de Lome; the "Couronne," built of iron, after plans of Mr. Audenet; and the two ram ships "Magenta" and "Solferino," built of timber after plans of Mr. Dupuy de Lome. The thickness of the iron casing in all these ships, as well as in those on the stocks, is the same—4¾ in. near the load line and 4¾ above that. The first three named ships have been already thoroughly

---

* A stere is equal to a metre-cube, or about 36 cubic feet.

tried at sea, and they are a perfect success. They have attained the superior speed of 13¼ knots, under steam alone, with men and armament on board. They roll easy, and do not pitch more than is usual. I have been on board of the frigate "Invincible," thoroughly examined her, and found that she has not strained in the least (as was reported)—that she is perfectly tight, and her ventilation is the best I ever met with in any ship, the air being pure throughout. The captain assured me that the ship steers like a pilot-boat, and that she never strained or leaked, and is an excellent sea vessel. All the appliances on board of these frigates, to make them real, efficient fighting ships, are admirable and ingenious.

The 10 frigates on the stocks are similar to the "Gloire" in their general outlines, but they are of a far superior model, will have easier motions, be faster still and carry their battery 14 in. higher. I think their shape could yet be improved upon; but, such as they are, I consider them to be the most efficient men-of-war ships yet laid down by any nation. Their principal dimensions are:—Length, about 265 ft.; breadth, 56 ft.; mean draft, 25½ ft.; and will render themselves always easily managed ships, obeying the rudder quickly; and they possess, in this respect, immense advantages over their over-large and overlong English adversaries, which, on account of their exaggerated dimensions, are almost unmanageable.

I regret very much to see, from the late accounts received from the United States, that our Government intends to construct a number of iron iron-cased ships (cruisers) of 7,300 tons each. How such a plan could be adopted, with the English experience of such large iron ships before our eyes, is more than I can understand. The comparatively small draught of water which these ships only can have, on account of the depth of our harbours, prevents a possibility of giving any great speed to such immense structures, and their necessarily immense length will render them less manageable yet than their English sister ships. Thus they will be at the mercy of a much smaller opponent, whose superior steering powers allows a choice in position.

The construction of such vessels would be as great an exaggeration as was the construction of a whole fleet of "Monitors," which, I know, will be acknowledged, are only fit for harbour defence, and which leave our navy of sea-going ships just as it was before we commenced the construction of iron-cased ships.

SEA-GOING QUALITIES OF IRON-PLATED VESSELS.

The fact of the safe arrival of the iron-cased frigate "Normandie" at Vera Cruz has dispelled all doubts that were expressed with regard to the possibility of iron-cased ships crossing the Atlantic. She is wooden built and coppered, performed admirably, and proved to be an excellent sea vessel; she rolled comparatively easy, and will, after lying four months at Vera Cruz, have preserved her original speed of 13¼ knots, while an iron-cased ship (like the "Couronne") would in the same time, from a foul bottom, attain a speed of no more than 8 knots per hour. This was the reason that the "Normandie" was substituted for this expedition instead of the "Couronne," which ship had already had orders to proceed to Vera Cruz. The "Gloire" and her sister ships, and also the "Couronne," have engines of 900-horse power, and are armed with 36 rifled 30-pounder guns throwing, shot of 70 lb weight, but breech-loading rifled 30-pounders are being substituted.

IRON RAMS.

The two ram frigates "Magenta" (at Brest) and "Solferino" (at L'Orient) are built on entirely different principles. The bow of these ships is admirable for the purpose designed. If their upper battery were removed, and the lower one plated from stem to stern, in my opinion they would be the most formidable vessels in the world. Up to the first battery these ships are plated from stem to stern, but in the upper battery only 12, and in the lower battery only 18 guns are protected by iron casing. The four rows of iron casing are 4¾ in. thick; the upper ones, 4½. Both ships are being built of timber, and I therefore consider it a bad plan to have left their extremities unprotected. Their shape and interior arrangements are almost perfect.

Their engines are 1,000-horse power; speed 13½ to 14 knots; armament consists in fifty-two 30-pounder rifled guns, on two decks. The "Magenta" is now ready for sea. The "Solferino" was making her machinery trials when I was on board, and she will be ready for sea before the middle of December.

IRON-CASED FRIGATES.

The names of the ten iron-cased frigates on the stocks are "Provence," "Savoie" and "Revauche," at Toulon; "Guienne," at Rochefort; "Heroine" (of iron) and "Surveillant," at L'Orient; "Gauloise," "Magnanime" and "Valeureuse," at Brest; "Flandres" at Cherbourg. These ships are all built from the same lines, and after the same plans. They are built exceedingly strong, and the materials used in their construction, as well as the workmanship, cannot be surpassed. Their engines (almost finished) will be of 1,000-horse power, and they are expected to realise a speed of 14 knots. Their armament will consist of 38 breech-loading rifled 30-pounder steel guns, throwing shot of 180lbs. weight, with which the stoutest armour plates have been penetrated at 600 metres or 660 yards distance. A considerable stock of these guns is on hand at L'Orient.

Work was progressing rapidly on the "Provence," "Flandre," "Guienne," "Heroine" and "Surveillant." The "Provence" will be launched in December. The other four ships can be completed before April next. All their beams were in, and they were ceiled and partly planked. The ribs and beams of the "Heroine" were in place, and the four lower streaks of plates were rivetted on. The remaining five frigates on the stocks all stood in frame, and with their beams in and partly ceiled, and can be completed if necessary before next June.

Thus France will have afloat by middle of next summer 16 iron-cased frigates superior in shape, speed, and steering powers to those of any other nation.

OTHER VESSELS.

Besides the iron-cased frigates, I found in Toulon on the stocks the "Tarne," a large three-decked steam-transport frigate of 500-horse power; also four second class screw gunboats on an improved design—six feet draught of water. At Cherbourg and Rochefort, two other large steam transport frigates are building. At Brest, two twenty-two gun frigates. At L'Orient, a gunboat. All these vessels are built of timber.

PRIVATE ESTABLISHMENTS WORKING FOR GOVERNMENT.

The private establishments are executing many orders for the Government. Mr. Arman, in Bordeaux, is building four light draught iron-cased floating batteries, from plans of Mr. Lemoine, in L'Orient. They will be plated with 6-inch iron throughout, and their armament is to consist of eight 180-pounder steel guns, and they will have two engines each 50-horse power, and be propelled by two screws under the counter. To obtain an exceedingly light draught these batteries are constructed of iron. They are named the "Embuscade," "Imprenable," "Protective," and "Refuge."

At the establishment of Mr. Gouin, at Nantes, three other iron-cased floating batteries are building, named the "Arrogante," "Implacable" and "Opiniatre;" are of iron and light draught; engines are of 150-horse power; and these batteries will be armed with ten of the heaviest guns, of which nine can be used on either side, also three could be used in a chase, or three in retreat. The speed of these batteries will be 6½ knots, which is considered perfectly sufficient. They are entirely different in shape from anything that has been constructed, and are what our Government should have had to take and to hold our Southern ports. The batteries in Nantes are only to be plated near the load line with 4¾ in. iron, and above that with 4¼. All these batteries will be completed by next summer. Several transport frigates, gunboats, and despatch boats are being built in the private establishments of Bordeaux, Ciotat, and Havre.

ENLARGEMENT OF NAVAL ARSENALS, DOCKYARDS, AND WORKSHOPS.

Works for the enlargement of the five naval arsenals are in progress. The dry dock accommodation is also being increased in all the yards. In Toulon, two are completed and the third is excavated, and all are of enormous size. In L'Orient one has been lengthened sufficiently to admit two ships of the largest class at a time. In Brest three are being cut out of the solid rock, and one of them is far enough advanced to begin the mason work. The workshops for the construction and repair of steam machinery in Toulon (at Castigneau) and at Brest are without any parallel for size and excellent arrangement. Steam saw mills, for cutting plank, curved, and bevelled timber, have been erected in Toulon, Brest, and Cherbourg, and are nearly finished at L'Orient and Rochefort, on the most extensive scale, showing again that the French naval authorities have come to the conclusion that man-of-war ships have to be built in future as before, of wood in preference to iron. The whole dockyard organization in France is of the most perfect description, and allows the Government to carry out its plans with the utmost rapidity. Thus arrangements have lately been made at Toulon and Cherbourg enabling them to put provisions and stores for an army of 60,000 men on board of a fleet in less than half a day's time, and the purport of this can be easily guessed. The plans for new vessels are not made exclusively at the Ministry of Marine, as formerly, but a programme of the works to be undertaken is communicated to all the dockyards—and all the naval constructors, of whom there are 122 in the service, are allowed to submit their plans to a commission, and the plan offering the most advantages, though perhaps coming from the lowest in rank, is adopted. To this excellent system, worthy of a free country, the present high standard of French naval construction is indebted.

WHAT THE UNITED STATES NAVY OUGHT TO BE.

In comparison with the power of the navies of France or England, I must confess ours is not worthy the name of a navy. In conclusion, I may be allowed to say, in order that we may be respected by all the European naval powers, we ought to commence without delay the construction of at least 12 iron-cased frigates of from 36 to 52 guns, each of not more than 25 feet mean draught of water. These will form the nucleus of our real fighting ships at sea. We ought further to have an equal number of corvettes of high speed, and of about 14 to 16 guns each, and about twenty of 30 to 50 gun frigates, and an equal number of screw steam sloops of war of about twenty guns each, both latter classes of the highest speed obtainable, so as to allow them to evade their iron-cased opponents. The latter vessels will always prove of excellent use in case of a foreign war in harassing the enemy's commerce. All these ships ought to be built of timber, and in the most substantial manner. Not until this increase has been accomplished shall we command respect as a nation.

Iron ships ought not to be adopted in our sea-going fleet, for the following reasons: 1. The fouling of their bottoms (against which no remedy has been found yet), and consequent loss of speed. 2. The weakness of their bottoms, and consequent liability of soon breaking up whenever they touch. 3. The impossibility to give them a good ventilation, all the artifical means having failed to produce a good ventilation, on account of the many water-tight bulkheads necessarily used in their construction. 4. Their great unhealthiness, as proved already by the few cruises made by the "Warrior" and "Defence."

Yours truly,
Donald McKay.

HOLMAN'S PUMPS AND BAR RUBBER VALVES.

Mr. Holman of Cannon-street, appears to pursue the study of hydraulics to good purpose. He brought out a double-action pump in the year 1854, which has been most extensively used. He also entered a provisional specification in the year 1857 (No. 1679), for improvements in force pumps, from which the following is an extract:—

"The chief object of this invention is to simplify the construction of force pumps by applying thereto an elastic compound valve, in place of the ordinary arrangements of clack and other valves. This valve is formed of a cup of vulcanized rubber, which is applied to the lower end of the pump cylinder between it and the inlet pipe, so that its bottom covers the inner end of the pipe, while the lip or upper part of the cup surrounds and lays closely against the cylinder which is pierced at that part with holes for the discharge of water from the cylinder."

It appears that Mr. Morris, the well known engineer of the Kent Water Works, patented the same valve in the year 1861, four years afterwards. The following extract is from the *Engineer* of Oct., 1862:—"The pump valve, patented by Mr. Morris, of the Kent Water Works (No. 323), 1861, has been provisionally specified by Mr. S. Holman in 1857 (No. 1679)."

The annexed illustration furnishes a new arrangement of the pump, and a new form of valve, both of which contribute to the production of a concentrated mechanical arrangement and a compact and simple pump. We have seen the model which Mr. Holman has at his office, 18, Cannon-street, which is provided with a glass barrel, through which the peculiar action of the valves may be observed; and there are one or two remarkable features in the operation of the valves which we think worthy of notice. The model simply represents an ordinary house-pump fitted with the bar rubber valve, in lieu of the ordinary clacks, the valves being placed in what may be termed bottomless grooves and seatings against the two sides, as shown in Fig. I of the annexed illustrations. The seating of the lower (or suction) valve is stationary, and that of the bucket moves up and down the barrel in the usual way. The inventor here realises the practical development of his theory, that "the fluid having a free passage on all sides of the valve, a comparatively free and unobstructed egress will be obtained; this is demonstrated in the following manner:—At the up stroke of the bucket the water passes through the lower valve, and in its distended position the valve moves freely in a circular direction, showing that the round sectional form of the valve maintains its central position in the issuing stream. This peculiar motion is also imparted to the bucket valve notwithstanding its traverse at right angles with the circular plane. The action or opening of the valve is comparatively little, and very quick; unlike the clack or other disc valves, it does not float away with the current to any unnecessary extent, but simply stretches out to allow the fluid to escape equal to the traverse of the piston, and closes instantaneously at the termination of the stroke in either direction. This arrangement will be found very useful for air pumps and blast engines, because the firm and steady seating of the valve secures the duty of the full length of the stroke.

FIG. 1.

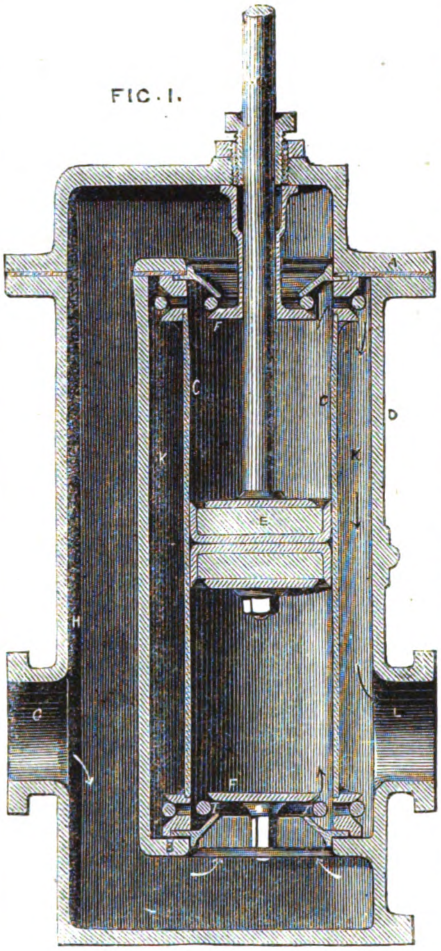

FIG. 2.

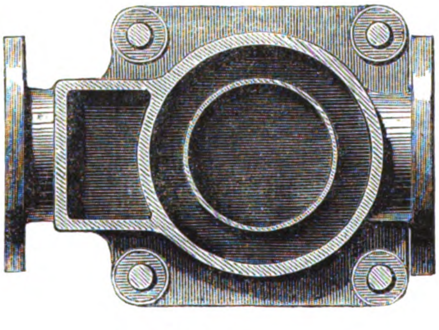

FIG. 3.

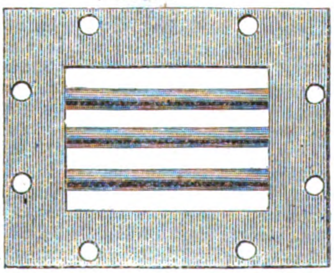

FIG. 4.

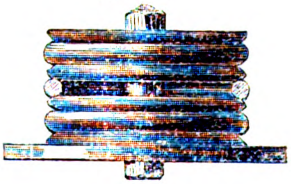


The following are extracts from Mr. Holman's specification:—This invention relates, firstly, to a novel arrangement of pump. The pump consists of a barrel or inner cylinder, placed within a cylindrical casing (which may be used as an air vessel) leaving a space all round between the inner andouter cylinders to permit the discharge of the fluid at or beyond each end of the barrel alternately. The piston, in its reciprocating motion to and fro in the barrel, operates upon the suction and delivery valves so as to cause the water or other fluids to flow into and out of the pump whichever way it is moved; it will thus be a double-action pump. The delivery valves are made to encircle the outside of the cylinder or working barrel or seatings at the top and bottom, the upper suction valve or compound valves (as the case may be) to encircle the rod and to be operated upon from the top side of the piston, the lower suction valve or compound valves to be placed on the seatings (which may be either cylindrical or flat), so as to be operated upon from the bottom side of the piston. The cover of the pump is constructed with a chamber or space formed all around the stuffing-box, so that at the descent of the piston the fluid will be admitted to the barrel above the piston through the upper suction valve or valves, and at the same time be forced out from the barrel by the lower side of the piston through the lower delivery valve or valves; and at the ascent of the piston the fluid will be admitted to the barrel below the piston through the lower suction valve or valves, and at the same time be forced out from the barrel by the top side of the piston through the upper delivery valve or valves. The bottom of the pump has also a hollow space or chamber for the water or other fluid to pass freely to the lower suction valve. The fluid may be conducted to the top and bottom of the pump by separate suction pipes, or by a suction pipe common to both, and may be discharged from the pump through one or more outlets in the outer cylinder or case. For many purposes no other support will be necessary for the working barrel than that of holding it between the pump cover and bottom, the cover and bottom of the pump being secured by bolts or any other convenient mode of fastening to the case or outer cylinder, are at the same operation made to press on each end of the working barrel, which may have flexible rings between to ensure soundness of joint, thus leaving the outside of the working barrel entirely free.

In this pump I leave myself free to use the flexible cylindrical valves, according to my specification, dated 16th June, 1857, No. 1679, or the disc valves, as frequently used in pumps, or new valves and seats made according to the following description, in the second and third parts of this invention:—

The invention consists, secondly, of new forms of pump valves and seats, viz., I purpose to make flexible valves of india-rubber or other suitable material, in such forms and proportions as that each valve shall close an opening or space by a lateral or inclined bearing against the two sides forming the seating for the valve. I purpose to make the valves generally of round pieces of india-rubber or other flexible material, and to form them in roundings, such as would be represented by making a round bar of iron into a hoop and welding it into an endless ring. The endless ring of flexible material thus formed may be either put or stretched on to a cylindrical seat, to be expanded therefrom by the action or pressure of the fluid against the inner surface, and to close thereupon when the pressure is removed from the inner surface; or they may be placed upon the surface as upon the area of a bucket; or they may be made in longitudinal pieces, either singly or several pieces connected at the ends or other parts, and placed at distances corresponding with spaces on the area of the seat. This invention consists, thirdly, of the application of a double ring valve made in U form, similar to the double cup leather used in hydraulic presses; the inner ring to form the suction valve and the outer ring to form the delivery valve, by operating upon seats adapted for them, or the outer ring may be made to form the suction valve, and the inner ring the delivery valve, according to the arrangement of the communicating passages.

In the accompanying engravings, fig. 1 represents the pump in longitudinal sectional elevation; fig. 2 is a section of the same. A, A, is the cover of the pump; B, B, the bottom; C is the pump barrel; D, the pump case (which can be used as an air vessel); E, the piston; F, F, the seats of the two suction valves; G, the inlet; H, the passage, communicating to the upper and lower suction valves; I, I, I, I, are the four flexible valves; K, the space or passage around the barrel, into which the fluid is forced at the ascent and descent of the piston through the upper and lower delivery valves; L is the outlet; M represents a hand lever; N, a spring stanchion; the spring in the stanchion obviates the necessity of a third pin, and reduces the number of wearing parts; but the pump may be worked by any ordinary method of actuating reciprocating rods.

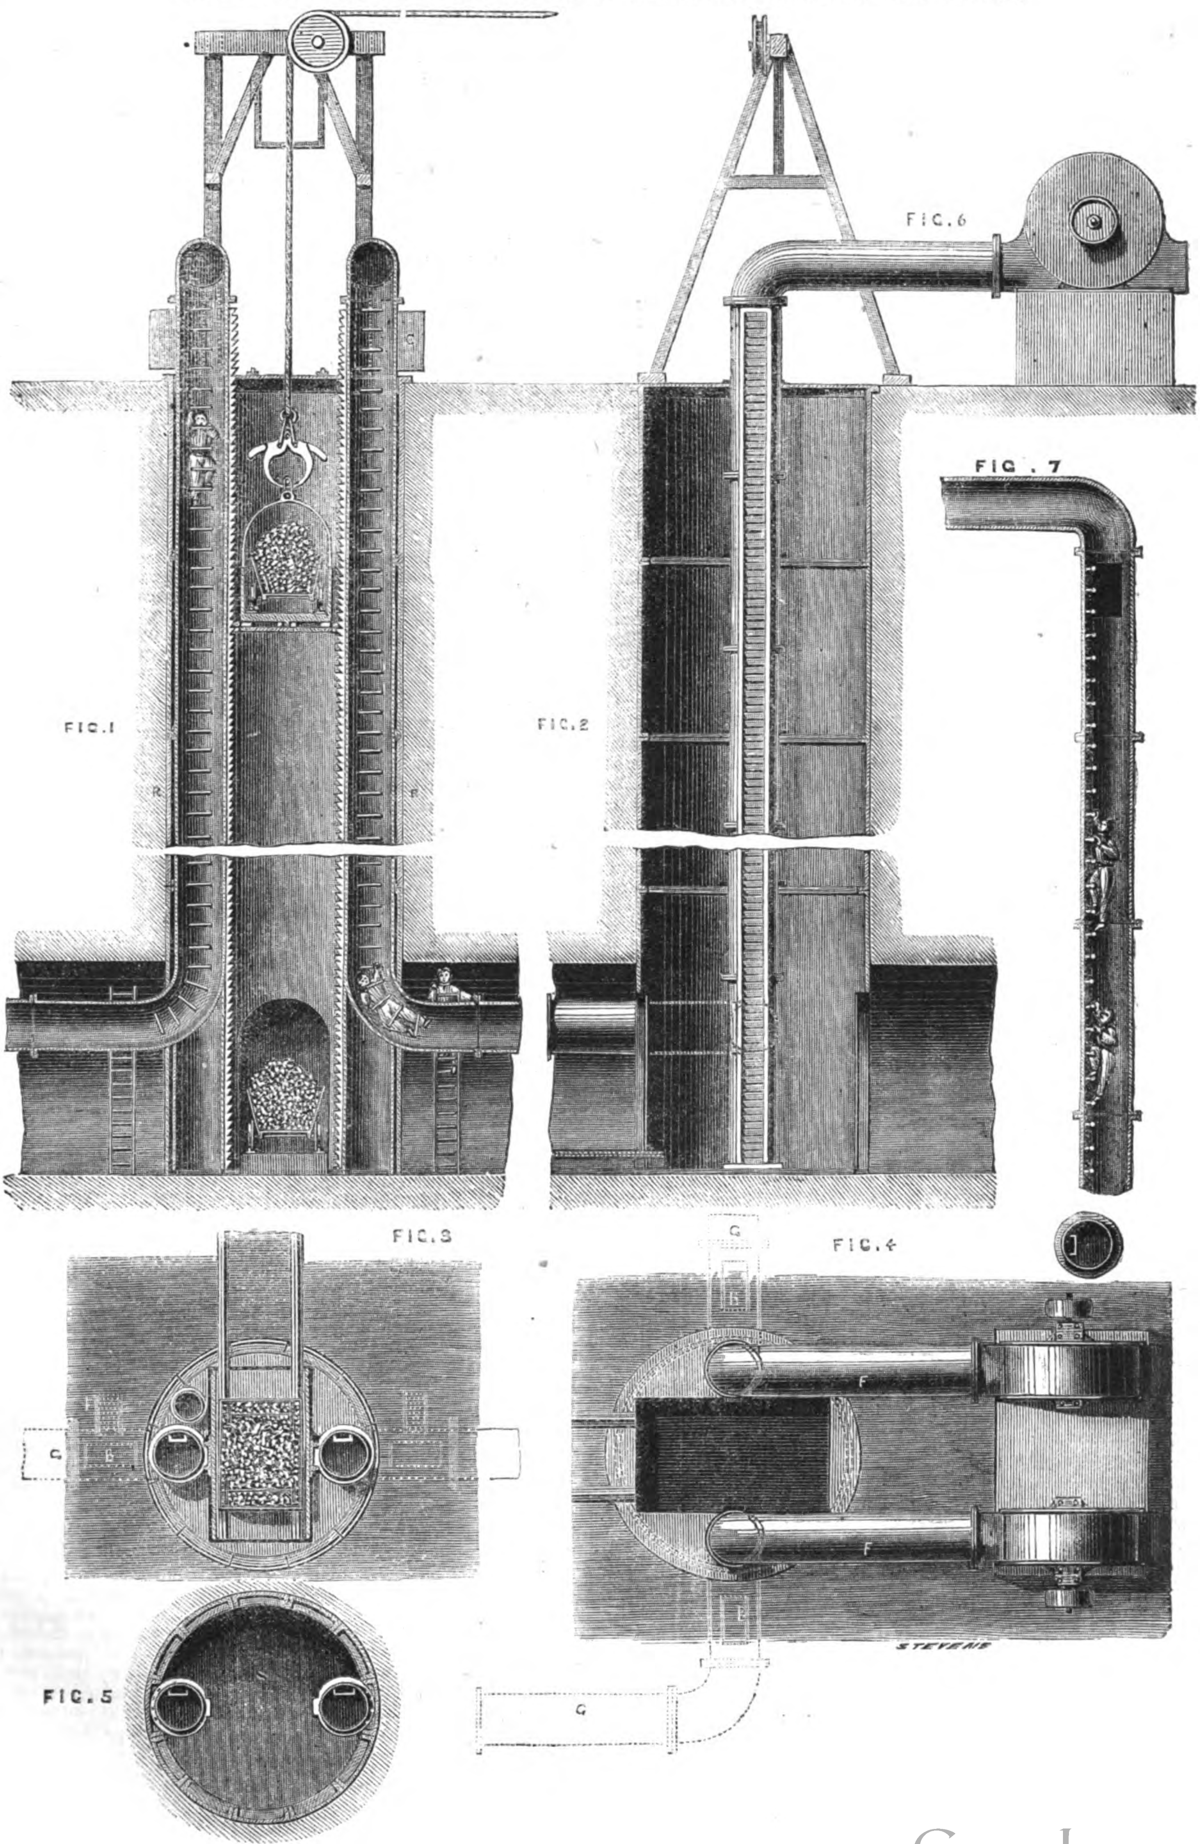
Fig. 3 represents a compound longitudinal valve in plan; Fig. 4 represents three conical ring valves on a treble space seat, the middle ring or valve being in section.

The action of the pump is as follows: — When the piston performs the upward stroke, the lower suction valve and the upper delivery valve will be expanded from their seats simultaneously, the fluid will then enter the barrel below the piston, and be discharged from the barrel above the piston at the termination of the upward stroke; these two valves (being elastic) will close quickly on their seats, and at the downward stroke of the piston the upper suction valve and lower delivery valve will be actuated in a precisely similar manner; the quick repetition of this action will effect a copious and continuous discharge at the outlet L.

We learn that Mr. Holman has secured his invention in England, France, and Belgium. And we hope it will have the success it appears likely to achieve."

Mr. J. H. Foley, the sculptor, has been elected a member of the Belgian Academy of Fine Arts.

RAE'S PLAN FOR THE PREVENTION OF ACCIDENTS IN MINES.—SEE PAGE 68.



THE ASSOCIATION FOR THE PREVENTION OF STEAM BOILER EXPLOSIONS, MANCHESTER.

A SPECIAL meeting of the Executive Committee of this association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, January 20th, 1863, Hugh Mason, Esq., Vice-President, in the chair, in order to take into consideration a retrospect of the transactions of the association during the past year of 1862; when Mr. L. E. Fletcher, chief engineer, presented his annual report relating to matters of an engineering character, from which the following facts are extracted:—

It appears that all the boilers under the care of the association have received their full complement of examinations during the past year, including an annual visit of inspection from the chief engineer; while the report goes on to say, "820 of these boilers have been examined 'thoroughly,' that is when empty and cold, when the inspector not only gets inside them, but also goes up the flues, so as to ascertain the condition of the plates and seams of rivets throughout. The number of these 'thorough' examinations this year is higher than it has been in any preceding one since the commencement of the association, and is nearly double that of last year." In consequence of this increased number of "thorough" examinations, it was stated, that a larger number of defects than usual had been revealed, and which would otherwise have been unknown; an additional illustration of the importance of these "thorough" examinations. "The defects discovered in boilers are mainly of two classes, one relating to their construction and the other to their condition. Under the first head, namely, that of construction, 196 recommendations had been made, which are as follows:—

"In 163 boilers the internal flue tubes have been recommended to be strengthened by hooping.

"In 18 boilers the shells have been recommended to be strengthened at the steam domes by stays of angle iron, &c.

"In 9 boilers the shells have been recommended to be strengthened at the ends.

"In 16 boilers the load on the safety valves have been recommended to be reduced."

Under the second head, namely, that of condition, 85 defects had been discovered, all of which were considered dangerous; they are as follows:—"Fracture of plates and angle irons, 13; Blistered plates, 1; Furnaces out of shape, 12; Corrosion, 37; Defective safety valves, 5; Defective water gauges, 9; Defective blow-out apparatus, 7;" others not actually dangerous, but still unsatisfactory, were then given, which need not here be repeated. The report then went into a detailed consideration of the defects discovered under each of the above heads; some of the remarks on corrosion may be given.

"Corrosion is found to be going on in all boilers more or less, and it will be seen that the greatest number of dangerous defects in the preceding table are to be found under this head.

"In one case a boiler set upon a mid-feather wall 15 in. thick, had a channel eaten right along it about 8 in. wide, which ran down the centre of the seating, while the plates at the edges of the brickwork appeared quite sound, and the danger consequently passed for some time unsuspected. In a second instance, with a mid-feather 2 ft. wide, the plate was found to be eaten almost through from nearly one end of the boiler to the other; while in a third, where lime had been allowed to come in contact with the boiler at the mid-feather, the plate was completely pulverized and could be carried away in handfuls. In a fourth case, a vertical tubular boiler had been placed close to a wall, one being in actual contact. Damp in the brickwork set up corrosive action in the plate, which being concealed by the position, went on undetected until the metal was completely eaten through, and a piece blown out by the pressure of the steam. The original plating of the boiler was thick, the pressure low, and the corrosive action local, only affecting a surface of about 12 in. square, so that the rent did not extend.

"Examples of corrosion might be multiplied indefinitely; enough, however, has been said to show the importance of having all parts of the boiler accessible to examination, the flues sufficiently capacious, and the seatings as narrow as possible, and also of having the brickwork removed occasionally, at all events in places, so as to ascertain the condition of the plates, since to conclude that the parts concealed are in the same condition as those in view has been found in practice to be fallacious."

Under the head of Explosions it was stated:—"It is to be regretted that no means exist of ascertaining the whole number of steam boiler explosions that occur throughout the United Kingdom, and there can be no doubt that many are never recorded at all. There are known, however, to have occurred during the last year no less than 31 explosions, from which at least 87 persons have been killed, and 88 injured. Of the number of lives lost by some of the above, no account could be obtained; while from one of them, as many as 29 persons were killed and 12 injured; from a second, 12 were killed and 24 injured; and from a third, 6 were killed and 8 injured.

"The following list gives the description of boiler to which the explosions have occurred, with the number of each class, as well as of the persons killed and injured:—4 Haystack Boilers—12 persons killed and 5 others injured; 6 Plain Cylindrical Egg-ended Boilers—6 persons killed and 6 others injured; 3 Iron Works Boilers—47 persons killed and 44 others injured; 3 Plain Single-flued Cornish Boilers—2 persons killed and 2 others injured; 2 Plain Double-flued Lancashire Boilers—4 persons killed; 3 Locomotive Boilers—4 persons killed and 2 others injured; 1 Agricultural Boiler of Tubular Portable Construction—4 persons killed and 4 others injured; 1 Kitchen-range Boiler—1 person killed. Also 8 other boilers, of the construction of which no reliable information could be obtained, but from the explosion of which 27 persons were killed and 22 others injured."

An analysis of the causes of explosion then followed, the summary of which only can be given:—"Of 31 explosions which have happened during the year 1862, 11 occurred to externally fired boilers, from failure of the plates exposed to the action of the fire; 3 resulted from internal corrosion, and 3 from external; in addition to which, 4 were due to improper original construction, one to shortness of water, and another to accumulated pressure through want of a safety valve; while 7 occurred at a distance which precluded a personal investigation of their causes, at the same time that no reliable information could be obtained with regard to them."

It was also stated that since the foundation of the association 8 years ago, "It has been found, upon limited inquiry only, that throughout the United Kingdom no less than 213 explosions have occurred, which have been attended with the loss of 472 lives, in addition to serious injury to 512 persons, and considerable damage to property."

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

AT a late meeting of the Manchester Philosophical Society (E. W. Binney, F.R.S., F.G.S., president, in the chair), Dr. Joule read the following letter addressed to himself:—

"Varagnes, near Annonay, Ardèche, France,
"November 25, 1862.

"DEAR SIR,—I am much obliged to you for the disinterestedness you have maintained in reference to the discovery of the great principle that my uncle, the celebrated Montgolfier, revealed to me some sixty years ago. Since that time I have passed my whole life in studying this question.

"Much merit is due to you, Sir, for your defence of another's rights, especially after the compositions which you have published, and are, without doubt, the best explanations yet written of the great principle so continually occupying you, myself, M. Grove, M. Mayer, and many others. Among the latter there are many who endeavour to persuade the public (every one in his interest) that the world owes the great advancement of the *dynamical theory of heat* solely to their works; but the public do not like being led in this kind of logic, and look with indifference upon the pretended authors of these discoveries, at the same time raising the merit of those, like yourself, who take a pleasure in rendering justice to those who wait patiently until just and impartial men judge them by their works and not by their words.

"For more than sixty years I have studied the question of identity of caloric and movement, and yet have perceived no advancement of this subject; nothing that either has been said or written has helped me towards the conviction I have arrived at. Indeed, almost all the experiments since then have proved this a fact (which formerly no one endeavoured to contest), viz., that immediately movement disappears, heat is produced, reciprocally. We cannot, however, praise too much your studies, and those of the physicists who have followed you, having witnessed the details of this great principle and calculated the different circumstances with the utmost accuracy. All the attempts in giving a plausible explanation of the phenomenon in question have generally conveyed this opinion, that the molecules of bodies, as well as those of ordinary matter, are liable to Newton's attraction, and, consequently, must be separated from each other by spaces infinitely larger than they occupied before; then, they must keep their distances from each other by virtue of laws, if not identical, at least analogous with those which govern the celestial bodies and maintain in fixed boundaries the distances between the planets and the stars, which determine their course.

"Such were the ideas I had, when addressing a letter on this subject to the celebrated and most learned Sir John Herschel, when president of the Royal Astronomical Society, the most distinguished man of our time for his philosophical genius and his wise and judicious manner of treating sciences, well known to me through the connection I have had with him.

"We are indebted, Sir, there is not a doubt, to the solid and enlightened spirit that characterises the English learned, for the development made in your country on this interesting question, which occupies the most learned men in the world. I have endeavoured to engage, by numerous papers, the attention of the members of the French Academy of Sciences, my colleagues, upon this important subject, but without avail. But I take the liberty of asking you to communicate this letter to the members of the institution of which you are a member, and, should I obtain its publication, I hope my studies will be known by all your learned colleagues, and contribute to enlighten the opinion of those who pursue this branch of science.

"The letter I addressed, on the 2nd of April, 1824, to Sir John Herschel, has been translated into English, and was sent to Sir David Brewster, who inserted it, on the 24th of April, 1824, in the 20th number of the *Edinburgh Review* (page 280), in which I expressed an opinion that the cohesion of the bodies constituted on the surface of the earth may be liable to attraction, which will tend to join in their centre of gravity the composed molecules. I also explained the great difficulty I had in attaining this result. Indeed, if the particles of invisible and invaluable bodies could maintain their distances by the same laws as the celestial bodies, the former would necessarily be perceived, for they would be obliged to collect themselves in a symmetrical and regular manner about their centres of gravity, and make their movements apparent to our senses. I have understood since that a law exists, unknown to me, determining the organized parts of bodies to keep a distance, and to preserve the permanent forms they exhibit. Therefore I studied incessantly to solve a question of so great an interest, and in 1836, after twelve years passed in study and meditation, I was fortunate enough to succeed. Indeed, an attentive examination of the manner of action exercised reciprocally by the particles and generally by all the bodies brought this result: If systems of two or several molecules, being comparatively in repose, traverse other systems comparatively in movement, the former separate the latter from another, losing a part of their own movement. Consequently, the question of cohesion was for me implicitly resolved; and, after eleven year's further reflection, I began to publish (in 1848) the series of papers I have read in the institute, and in which I proved, under the name of Distension, the new result of Newton's attraction applied by myself.

"Then, making myself better acquainted with this law, I published, in 1855, a large volume upon cohesion, and in 1859 another upon the origin and propagation of force, in which I have perfectly explained these principles, trusting to my own proofs and experience. Moreover, I published in 1861, in the form of a letter addressed to M. Tramblay, director of the *Cosmos*, a third paper in reference to the same subject. But yourself, Sir, a physicist of the greatest reputation, and who have taken quite a different direction in science not attempted by any other, must know very well how difficult it is, even for those who sincerely wish the triumph of truth to leave ideas and old practices in which they have grown up. To attain this result, we must have confidence in ourselves. New ideas, however clear and judicious they may be, are never adopted immediately, but by degrees, so that those who are occupied with the same question, already explained by their predecessors, fancy themselves the discoverers and authors. After several generations, however, when the tomb is closed above all, historians and commentators will re-establish the truth of the facts, and render them due justice.

"Mr. Faraday, your fellow-countryman, gave me that great satisfaction, and his powerful testimony has paid me more than I ever could hope, for the oblivion with which several of my contemporaries wished to cover me, who endeavoured to uphold one another without attaining anything but ridicule, the public always being just and free from prejudice, even if the question is above their intelligence.

"Let us console ourselves, Sir, should our efforts rest in obscurity and not be valued as we suppose just; let us be assured that those who will follow us will know how to sift the true from the false, that they will adopt the one and reject the other; and that, if the opinions we have exhibited are just and exact, they will be duly valued one day. But we shall not complain for the present to see our reputation injured by errors we have incurred, perhaps at the first moment, for these errors will have the definite result of classing us according to merit in the history of science. I am, &c.,

SEGUIN, Aine.

(M. Seguin also claims to have invented the tubular boiler).

In connection with a conversation on the solutions of different salts with which almost all the waters in England are contaminated, and the practical evils resulting from these impurities to steam-boilers, Mr. Spence stated that various means had been adopted, with only partial success, for preventing incrustation on boilers caused by these impurities. For some years he had adopted a simple plan, which is perfectly successful, both at Goole, where the Aire and Calder Canal has a considerable amount of lime salts, and also at his Newton works, where the water from the Rochdale Canal is not only impregnated with lime salts, but apparently also with sulphate or chloride of iron. The plan is as follows:—On the suction part of the water-pipe by which the boiler is supplied, that is, between the force-pump and the canal, a small vessel is placed, capable of containing about two gallons, of water; a pipe of half an inch diameter, with a stop cock, communicates from the water-pipe with this vessel; every day the boiler man puts into this vessel 1 lb. or 1½ lb., as found sufficient, of soda ash, and dissolves it in water in the vessel, and then, when pumping into the boiler, turns the small cock, and in three or four minutes all the solution is taken up and passed through the force-pump into the boiler, and this is daily repeated; the consequence is, that not the slightest crust forms on the boilers, and no chipping is ever required, the salts being all decomposed, and the earthy and metallic bases thrown down as mud, which may be blown off or cleaned out periodically, if the boiler is a flued one. These two boilers are cleaned monthly, and a broom and shovel are the only tools required. The plan is easily adopted, perfectly efficient, and very generally applicable.

Dr. Joule drew attention to the great sacrifice of life by steam-boiler explosions. He believed that, in nearly every instance, rupture took place simply because the iron, by wear or otherwise, had become unable to withstand the ordinary working pressure. Various hypotheses set up to account for explosions were worse than useless, because they diverted attention from the real source of danger. He believed that one of these hypotheses—that which attributed explosions to the introduction of water into a boiler, the plates of which are heated in consequence of deficiency of water, was quite inadequate to account for the facts; although weak boilers might be exploded at the moment of starting the engine, in consequence of the swelling of the water through renewed ebullition throwing hot water over the heated plates. The absolute necessity of employing the hydraulic test periodically had been pointed out so frequently that he considered that the neglect of it was highly criminal.

AT the ordinary meeting of this Society, on the 13th inst., Dr. JOULE described a peculiar kind of mirage which he had witnessed from the northern extremity of Douglas Bay, Isle of Man, and at an elevation of twenty feet above the surface of the water. At about nine a.m. a number of chimneys in the town were fired, and the products of combustion were driven out to sea by a very gentle breeze. Presently the wind changed, and drove the smoke at right angles to its former track. The steamer for Liverpool had, in the mean time, attained a distance of about three miles, and, although somewhat obscured, was distinctly visible through the smoke. Noticing something extraordinary in her appearance, he viewed her through a telescope, and then observed that nearly the whole of the hull was obscured by the horizon, the uppermost part of the paddle-boxes, the bowsprit, and tafferel being alone visible, whilst at the same time the masts and funnel appeared considerably elongated. Quarter of an hour afterwards, when the smoke had cleared away, and the steamer was about seven miles distant, the hull was seen as usual, quite unobscured by the horizon. Dr. Joule attributed the phenomenon to a stratum of highly refractive gases, lying about 20 ft. above the level of the sea and gradually diluted and diminished in extent on its upper and lower sides, so as to produce the effect of a convex lens.

Dr. ANGUS SMITH said—I saw once a very remarkable instance of the diversion of the rays of light from the straight line. Although fogs are common on our hills, I have met no instance of similar exaggeration of effect among us. I went with some friends up Skiddaw, and near the top entered a cloud which prevented us from seeing many yards before us, although it was not extremely dark. When moving over those loose stones which form a highway to the summit for a considerable distance, we observed a building which appeared to us about 14 ft. high. The side towards us seemed to be a wall nearly square, and we took it for granted that the top of the hill was attained and that the foremost of the party would be found there; but as we approached the building sank; and in the course of a few steps it went downwards until we found that there were only three layers of stones not very thick, and the whole under two feet high. The disappearance must have occurred within the space of twenty feet; my present impression is that it was less. Further on we attained the man at the summit, and the cloud became denser; we could not see many feet, and I did not think it safe to move from the spot for some time, not knowing the locality. Sitting there I saw four perpendicular lines on the cloud; I looked up and found that they terminated in the body of an animal which was moving slowly towards us. The distance could not be measured, except by the number of steps taken by the animal, and from these I concluded that when first seen it was from twelve to twenty feet from us; I looked on twelve as being most probable. I do not exaggerate when I say that the height was in appearance 30 ft. Wondering what to be the end of this strange vision, I called the attention of all, but the animal diminished in size so rapidly that only one or two, who instantly attended to my call, could perceive the monstrousness of the exaggeration of form now presented by a moderately-sized pointer. On coming up to the more advanced portion of our party, they were enlarged and distorted, as we often hear described; but such effects are comparatively common, and they are not to be compared with the two instances mentioned. The first was seen with my face towards the sun nearly. It was about midday. The second phenomenon was seen 20 minutes later, when looking nearly north.

Although I have lived much in sight of Morven, where one might expect to see the "spirit of the mist on the hills," I had not seen anything similar before, nor have I gained from the shepherds that such things are common. Perhaps if they were common, Ossian's ghosts would be less imposing.

MICROSCOPICAL SECTION.

15th December, 1862. Mr. J. G. LYNDE, F.G.S., M. Inst. C.E., in the chair.

The CHAIRMAN stated that he was led to pursue Dr. Roberts's suggestions on the use of magenta dye in examining tissues. From experiments made since the last meeting of the section, he finds that the dye has no power to colour living tissue, whether animal or vegetable, but that as soon as life is extinct the action of the dye commences. He is continuing the experiments, which are of a most interesting character, and he hopes to lay the result before the next meeting of the section.

Mr. LEIGH considered it probable that so long as vital action continued, ordinary endosmosis could not take place.

Mr. MOSLEY said that Mr. Hepworth had frequently tried magneta for injections, and the results were not satisfactory, as the colouring matter diffuses itself through the whole of the tissues, giving an appearance of dyed flesh rather than that of injected preparations. This appears to confirm the preceding observations, and to account for the accumulation of colour where the integument is thickest, by means of which Dr. Roberts discovered the spot on the red blood discs, as announced at the previous meeting.

Mr. LEIGH drew the attention of the section to the adulteration of size as a cause of mildew in cotton goods.

Mr. WATSON named the investigations made by Mr. Thompson about twenty-five years ago, as to the cause of mildew in madder purple-printed cottons shipped to hot climates. It was attributed to the starch employed in finishing the goods, which, acted upon by moisture, heat, and pressure, had given rise to an organic acid which discharged the colour.

Mr. HURST described his experience of mildew on printed cottons and upon dyed fustians, at Gibraltar and Calcutta. In most cases it appeared in spots and round patches, which affected the colours. On the fustians, he had no doubt it was caused by the growth of a fungus, as the surface of the spots was sensibly raised.

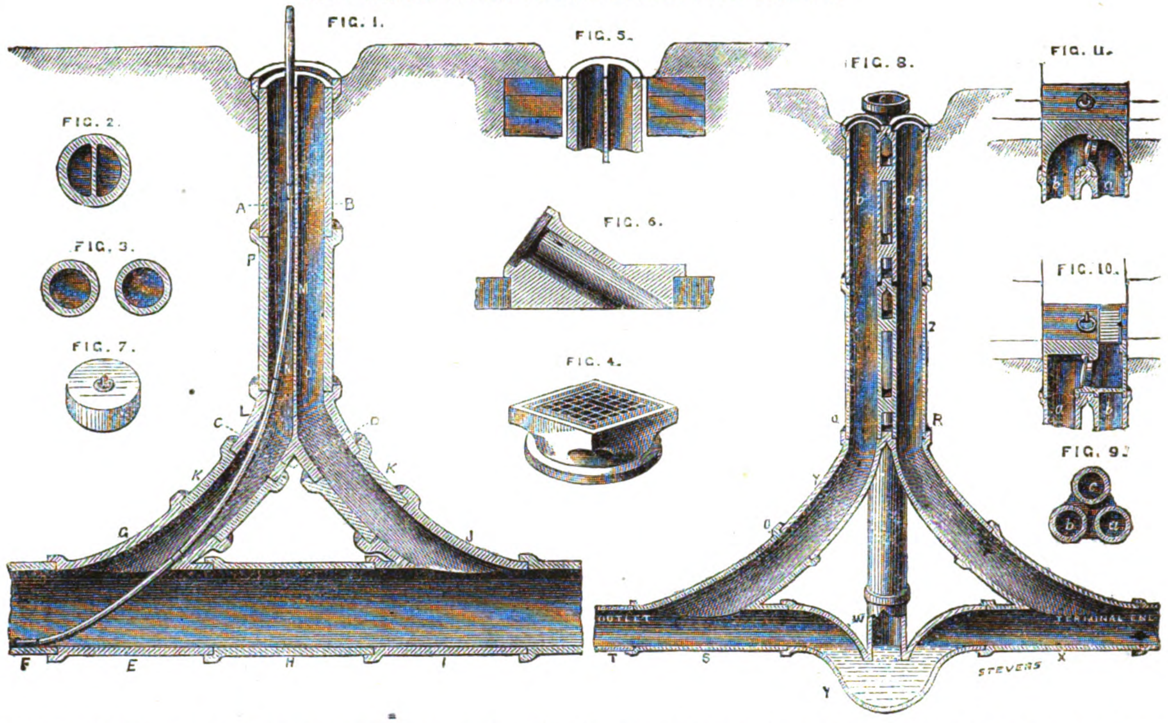
Mr. MOSLEY considered there might be several kinds of mildew; that upon the fustians might be attributed to the size with which those goods were generally furnished, and known by the characteristic smell. Mr. Mosley also exhibited a pattern of grey calico, which had become discoloured and quite rotten in irregular patches, from mildew; it had lain for some time in a damp place, under pressure; there was this peculiarity about it, that the coloured patches whilst damp were quite tender, but on exposure to the air and drying, the cloth had recovered its strength.

Mr. HEYS remarked that twenty years ago he was engaged in the manufacture of fine muslins; it was usual to soak the weft in soap suds to facilitate the weaving: and it was found the cloth was most liable to mildew during hot, close, summer weather, and the greater the quantity of goods heaped togther the more rapidly would mildew set in. The flour from which the size was made was always the best that could be purchased.

Mr. HEYS exhibited mounted specimens of the fibres of the Zostera Marina, and stated that, as the fibre is considerably finer than the finest Sea Island cotton, it might probably be of use in the manufacture of fine muslins for ladies' dresses, if possible to obtain a supply, and separate the fibre from the plant by machinery. Mr. Heys also exhibited mounted specimens of Queensland cotton, lately sold at five shillings per pound; the fibre is very regular in size and much more cylindrical than other cottons; also several specimens from ripe and unripe pods; and Mr. Heys expressed the opinion that great advantage would arise from a regular and careful examination of cotton fibre taken fresh from the plant through every stage of growth.

YELLOW SPOTS ON LEATHER.—Yellow spots on leather frequently occur, and these detract from its value. A correspondent of the *Shoe and Leather Reporter* says they are caused by decomposition in the hide, probably in the sweating process. The remedy, he says, is "more care in the manipulation or working of the hides. With good, cold spring water for soaking, and with a sweat-pit kept at the right temperature, with ice or otherwise, and a cool, sweet liquor for the first stages of handling, there is but little danger of being troubled with yellow spots on leather."

NEW ARRANGEMENTS FOR INSPECTING DRAINS.



NEW ARRANGEMENTS FOR INSPECTING DRAINS.

MR. J. LOVEGROVE, surveyor, of Dalston Rise, has recently obtained a patent for an arrangement of appliances for inspecting small sewers and drains, which he describes as follows:—For the purposes of ventilation, inspection, or flushing shafts at intervals over small drains and sewers, they are constructed from the top of the sewer to the surface of the ground, partly vertical and partly curved, and also in two divisions (for a double shaft), so as to admit of the passing of a bamboo cane (screwed together in short lengths) down one division of the shaft turning into and along the sewer, towards the outlet for any distance, and thus to effect the removal of any obstruction that may have formed between the shaft and the distance reached. Also down the second division of the shaft, turning into and along the drain towards its terminal end for any distance, and thus remove any obstruction that may have formed in this portion of the sewer. The shaft is covered with a marked box adapted, either for carriage or foot roadways, that can easily be opened or lifted off without breaking the ground.

In the construction of ventilating and inspection shafts over house drain traps, they are constructed partly vertical and partly curved, and also in three divisions, so as to admit of the passing of a bamboo cane down one division of the shaft towards the outlet of the drain, or down the second division towards the terminal end of the drain, and down the third division (forming triple shaft) into the syphon dip trap, and thus in each of the places reached to remove any obstruction that may have formed. This shaft is covered with one of two marked box covers, dependant on the mode adopted for the ventilation of the drain, *i.e.*, if the drain is ventilated above the roof, or from its terminal end, then the shaft is covered with a box cover containing an air supply valve, to admit air into the drain down one of the vertical shafts on the inlet side of the drain trap, to pass all through the drain to the exit at its terminal end; and if the drain be ventilated into the sewer, then the shaft will be covered with a marked box cover to contain an air exit valve, to admit from the shaft on the inlet side of the dip trap upwards to and through the exit valve, and down the shaft on the outlet side of the dip trap, the foul air contained or generated within the drain. The dip trap and box valve together sealing the foul air from the sewer. The valve is opened by the pressure of the contained air, caused by a barometic difference of temperature between the air contained in the two shafts, or by the sudden influx of water.

The annexed engravings illustrate the invention more fully.

Fig. 1 is a vertical section of a double shaft for a small sewer; Figs. 2 and 3 are cross sections through the lines A B and C D.

A junction pipe E is inserted into the sewer pipe F with its mouth G curving upwards from the top of the sewer, and downwards in the direction of the outlet, then, next adjoining to and in extension of, this junction pipe, is placed an ordinary pipe H; and then, in further extension, a pipe with a reverse curved junction I, the junction J curving from the top of the sewer, also upward (but downwards), in the direction of the terminal end of the sewer, and the upper part converging towards the first named junction G. A bend pipe K, of a fixed minimum radius, with socket flange at the upper end, and spiggotted at the lower end, is inserted, one in each junction mouth, still more converging towards each other. A breeching and double junction piece L L is then fixed, having two spigot ends downwards and one socketted end upwards, divided by a diaphragm M, and so made that the two spigot ends shall fit into the socketted bends. The top of this breeching piece terminates the curved portions of the shafts, and the vertical portion P commences, which is continued to the surface. This is formed in short lengths of pipe, in iron or stoneware, having a diaphragm M throughout its length, thus dividing the shaft into two sections, N O. The diaphragm of the vertical shaft fits over the diaphragm of the breeching piece, thus forming a separate communication with each curve as it diverges from the bottom of the vetrical shaft towards the outfall, and also towards the terminal end of the sewer.

Fig. 4 is a cover in iron for carriage-ways to indicate the position of the shaft; Fig. 5 shows the top of the shaft with brickwork bed for carriage-ways to receive iron box; Fig. 6 is a longitudinal section of a junction block, used in lieu of the junction pipe J and G in the case of brick sewers. A plain block is then inserted in the arch of the sewer between the two junction blocks, in lieu of the pipe H.

In searching for or removing obstructions, the box is opened and the cane passed down one side of the diaphragm of the perpendicular shaft; the breeching piece gives direction to the cane, which then passes the curve into and along the sewer towards the outfall or terminal end, as may be desired, for any length.

Fig. 8 is a vertical section of a triple shaft for house drains. Fig. 9 is a cross section through the line Q R. Fig. 10 is a marked box cover, containing an air supply valve, fixed there for a ready examination; Fig. 11 is a marked box, containing an air exit valve, also placed here to admit of ready examination.

In the construction of the triple shaft over house drains a curved junction pipe S is inserted into the drain pipe T, with its curved junction mouth U curving upwards from the top of the pipe with a socket flange; then, next adjoining to and in extension of this junction pipe is fixed a syphon dip trap V, with a perpendicular junction mouth, with socket flange W brought up from the centre of the dip, and in further extension of this syphon dip a curved junction pipe X, curving from the top of the pipe upwards, but in the direction of the outfall, and convergent to the before-described junction mouth U. A bend pipe, Y, of a minimum curve, is then fixed with its spigot end, one in each of the three junction mouths converging so as to bring the three bends at the top or socketted ends together, or contiguous to each other. Three vertical pipe shafts Z, united so as to form a triple shaft with spigot and socketted ends, are fitted into the sockets of three bend pipes just before described. These triple shafts are then continued in short lengths to the surface, where it is covered with one or other of two box covers, dependant on the arrangement of the ventilation of the drain, *i.e.*, either a box cover, Fig. 10, with an air supply valve to supply air to the drain through and down one of the three shafts *a*, and through the drain to its terminal end, and thence through a pipe continued above the roof; or a box cover, Fig. 11, to contain an air exit valve to admit from the shaft *a* on one side of the valve upwards, and pass through the shaft *b* on the other side of the valve downwards, and thence into the sewer, the foul air contained or generated into the drain. The dip trap V and box cover together sealing the foul air from the sewer.

TO CORRESPONDENTS.

RECEIVED.—**J. A. D., J. G. F., J. N., Capt. N., P. F. A., J. F., R. T., S. H., H. B., S. T. G., E. J. R., E. B., W. S., J. T., J. W.**

A READER.—Supposing that all your tubes were perfectly homogenous, which is physically impossible, and that all were exactly alike in dimension, which is mathematically impossible, all the tubes would give way at one and the same time. With solid bars, instead of hollow tubes, the result, of course, would be the same.

T. F. (Manchester).—Giffard's injector *does* incrust in the annular water passage round the steam nozzle when hard water is used.

H. J.—We believe that Mr. William Fairbairn first introduced the side-lever arrangement of engines.

Correspondence.

◆

GUNS AND PROJECTILES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Under the above heading, in your valuable journal of the 23rd, I notice a letter by "Cosmopolitan," and also a description and an engraving of a flat-fronted shell for penetrating iron plates, which has been patented by Mr. Whitworth. By your kind permission, I would like to make a few remarks on these subjects.

I observe, both in the letter alluded to above, and in your article on the 9th instant, the hexagonal groove system is ascribed to Mr. Whitworth, and the oval system to Mr. Lancaster. Now, Messrs. Wilkinson, of Pall-mall, have in their possession, or had a year or two ago, an old Lapland rifle, *hexagonally* bored, exactly as used by Mr. Whitworth.

The oval bore of Mr. Lancaster will be found described in a work called "Seloppetaria," published in 1805, by Colonel Beaufoy. The narrow linear groove, or "saw-tooth" rifling, as it may almost be termed, as used by Sir W. Armstrong, I saw more than twenty years ago in a Belgian rifle belonging to one of my friends, which had been in his possession for many years. The ribbed bore I saw many years since in a rifled pistol; and I believe there are revolvers yet made so, and with a very little trouble; examples are to be found in existecne of all the known "new" systems of rifling, many of which have been in existence for half a century.

I will now turn to the question of flat-fronted percussion shells, and also flat-fronted shot, for penetrating iron plates, the invention of which is now ascribed to Mr. Whitworth, and also patented by him. In the year 1824, Captain J. Norton completed an elongated rifle shot and shell, and in 1826 we find him using them at Dublin, Woolwich, Addiscombe, and Sandhurst, as well as various other places, *with complete success*; but we find the wise acres then in power opposing their use on many grounds, one of which—and I may say about as good as any of them—was the "liability to wear out by carriage in the soldier's pouch!" In 1832 we find Captain Norton, at Windsor, firing a *flat-fronted steel* punch-formed rifle shot from an air gun, through a Life Guard's cuirass, and exploding powder placed on the other side. This steel, punch-fronted rifle shot was tested at Woolwich in 1828, and Captain Norton stated that it might "also be converted into a shell by drilling a hollow tube into its front," just as shown in Fig. 2 of Whitworth's patent. In the shipbuilding yard of Messrs. Leckie and Beale, at Cork, we find Captain Norton perforating a three-eighth boiler plate, at a distance of forty, and also sixty yards, with his flat-fronted shot. In the concluding part of his patent specification, as quoted in your journal of the 23rd instant, Mr. Whitworth says, "The form which I find to be the best compromise for a penetration shell is that shown," whereby one might be led to believe that the invention of the flat-fronted shot and shell belonged to Mr. Whitworth.

Now, I think it will be pretty evident, from what I have stated, that all Mr. Whitworth can claim is the *mode* of manufacturing shell as described in the specification, and that the form of bore adopted by him is not new; all that is novel being a quick pitch, much quicker than that of any other maker, because we find Captain Norton using and describing *flat-fronted* shells and shot, as the proper form for penetrating iron plates; and he also, many years since, in the MECHANICS' MAGAZINE, though I do not remember the date, states that "if gunpowder is placed within a box made of boiler plates, and the plate is pierced by such a flat-headed steel bolt, *the powder within will be exploded by the heat generated by the blow*.

Now here again is proof of the credit due to the indefatigable Captain Norton, who seems to have possessed the unpardonable fault of being a man before the time; for to him we owe the *expanding* elongated bullet, not the "wood plug" absurdity in use, but a real, sensible, useful shot, the explosive percussion shell, the *flat-fronted shot* for punching holes in iron plates, the credit of which, as well as the use, is tried to be made a monopoly, and various other matters, all of which he has the great merit of having "practically" tested, and not brought forward "on paper."

It is a great disgrace to this country that some substantial acknowledgment has not been long since made to this veteran, who has smelled powder, and been in active service in most parts of the globe, besides having had his share in the great struggle in the Peninsula. One cannot help contrasting, in some bitterness of feeling, the rewards that are heaped on the "featherbed" gentry, who have so laboriously served their country in doing nothing, and the fact that as yet no notice (substantial as it should be) has been taken of his inventions, all of which are now being brought out by others, who are deriving both credit and money from them, whilst the real inventor and first user, is not recognized, is a fact far from creditable to the powers that be; and one cannot help thinking, that if the inventor had laid his plans before another power, we should have had, by the results, additional proof that they "manage these things better in France."

Cannot some gentlemen of influence be got to join in getting up some acknowledgment of Captain Norton's genius? I should be glad to join in trying to do so.

I am, &c.,
C. F. T. Y.

Adelphi, Jan. 26, 1863.

HYDRAULIC PRESSES.

Sir,—In your journal of January 23d, you describe certain improvements in hydraulic presses, recently patented by Messrs. Peel and Simpson, of Manchester, upon which I beg, with your permission, to offer a few remarks.

In the first place, I find that the telescope arrangement of the cylinders and rams claimed in the above patent is already described in the specification of Michael Scott, No. 2713, dated 29th Oct., 1861. Secondly, with reference to the air vessel described, the same does not appear to me to offer the advantages of the ordinary weighted accumulator. The former, as well as the latter, has to be charged with the requisite quantity of water by means of the pumps. In working the press by means of the common accumulator the pressure remains constant, whereas with the air accumulator the pressure will diminish in proportion to the rise of the ram, whilst at the same time the resistance increases. If the ordinary low pressure accumulator be weighted to 1 cwt. per square inch, the ram will rise, till the resistance amounts likewise to 1 cwt. per square inch. It is evident that for producing the same effect by means of the air accumulator, the pressure in the same, at the end of this part of the stroke, must also be 1 cwt. per square inch. Supposing that for the completion of this part of the stroke the air has expanded to double its volume, it is evident that its pressure at the beginning of the stroke must have been equal to 2 cwt. per square inch, and from this it follows that the power required for charging the air vessel is far greater than that necessary for filling the common accumulator.

From the above it is also quite plain that the water cannot possibly return from the cylinder to the air vessel, as stated in the description.

I am, &c.,
January 27, 1863. S. S.

"INTERNATIONAL ASSIMILATION OF PATENT LAW."

Sir,—The excellent article in your issue of Jan. 16, contains a sentence in regard to the state of the American Patent Law which may prove injurious to the interests of European inventors, who have or shall hereafter secure patents in the United States.

Speaking of the patentee, it is stated "he discovers that he is everywhere, except in England and America, obliged to put his patent to work within a time generally varying from a year to two years." Instead of the United States forming a real exception to this general rule, under the Act of 1836, sec. 15, it is sufficient answer in a suit for infringement, to prove that the patentee, if an alien at the time the patent was granted, had failed and neglected for the space of eighteen months from the date of the patent, to put and continue on sale to the public, on reasonable terms, the invention or discovery for which the patent was issued.

Whatever might have been the intention of the framers of the Act of 1861, which equalized the patent fees, they failed, in this respect, to place the alien in the same position as the citizen.

The article contains the following rule of the United States Patent Office:—"The taking out of a patent in a foreign country does not prejudice a patent previously obtained here; nor does it prevent obtaining a patent here subsequently." By the Act of 1836, a person was debarred from obtaining a patent if the invention had been patented in a foreign country more than six months prior to his application in the United States. This clause was repealed by Act of 1839, sec. 6, and on this section the above rule is based. The repeal is made, however, with an important proviso, viz.:—"That the same shall not have been introduced into public and common use in the United States prior to the application for such patent. It will be well for inventors who intend to secure patents in the United States to bear this provision in mind.

I am, &c.,
GEORGE HASELTINE.

12, Southampton Buildings,
January 19, 1863.

Sir,—The articles which have appeared in your Magazine will, as I think, render good service to the cause of inventors. It is, I believe, universally admitted that the patent laws, both of England and of foreign countries, require revision. I have, myself, lately drawn the attention of the legal profession to the subject, feeling that, as a commission has lately been appointed, the present is an adventitious time for suggestions. The subject is a difficult one for legislation, as indeed it has always been since the celebrated "Statute of Monopolies"

An "international assimilation" of patent law is, I fear, too much to expect. The idea is good, and beyond doubt such a thing is desirable, but there are two difficulties in the way, which I venture respectfully to suggest, viz:—

1. The delay which must take place in getting all countries to adopt one system.
2. The corresponding difficulty which would attend the alteration of any system.

Even in England, at present, no system is as yet suggested, even by inventors, so far as I am aware. Patents are based, as we know, upon a sort of contract between the people and the inventor, the Sovereign acting as the representative of the people's interest. I fully agree with you, that it matters not whether an idea be "embodied in a mechanical or chemical combination; or whether it be developed in a product of art; or it be expressed in a literary work; it is an international benefit." But the great question to be settled is this: *Should the novelty be local or universal?* In strictness, no doubt, as I apprehend, the novelty should be universal—for if not so, how is it a "new idea?"—but the English laws are based upon the assumption that the invention is only within their realms. Perhaps in a future letter I may have a little to say as to the patent laws of other countries, but I reserve my observations for the present.

An "idea" is clearly, I think, a man's property. It may be the result either of reflection or investigation. On some occasions it is the result of instantaneous observation, but the idea, nevertheless, I think, involves a "property." But whilst this is so, the novelty and utility of an invention should, as I think, be tested by a scientific tribunal. A large number of inventions are, comparatively speaking, useless, to say the least. This being so, it must not be forgotten that the public have their rights as well as inventors, and it not unfrequently happens that a patent is a very serious restriction upon the rights of the public. It is no easy matter to "balance the scales" equally, so as to give a reasonable protection to inventors on the one hand, and to the public on the other hand. The subject will now, I think, be reviewed in a fair spirit, and it is to be hoped that a less objectionable system of patent laws will be the result.

I am, &c.,
T. CULVERHOUSE.

3, Compton-street, Ballspond,
January 19, 1863.

THE CAUSE OF APPARENTLY *COLD* STEAM.

Sir,—It has been suggested to me, that, for its more extensive reading, I make the following communication to your pages:—

The cause of what is termed *cold blowing* steam is generally considered to be the recovery of i capacity for receiving heat, which then becomes latent, it being supposed that the superheating of steam, or rather the spaces (interstices) surrounding its particles, in some way, prevents the steam itself from receiving its proper accession of heat; but this explanation, the notion of latency as regards *the thing itself*, rapidly losing ground among men of science, will not, I apprehend, long be tolerated as the *received* opinion; on which ground, and also because I am convinced of its falsity, I here present the reader with the following eminently practical explanation:—

The phenomenon may be accounted for by the enormous increase of the steam's expansive force, which is clearly the consequence of its superheating, the abnormal heat furnishing it with a truly prodigious elasticity, which elasticity, causing its particles, when the steam escapes, to be driven asunder with inconceivable rapidity; prevents the sensation of heat from being experienced; each particle, when the hand is placed in the steam, passing over all its parts too rapidly to raise the friction known as heat, from which cause we have the phenomenon of *cold* steam. I must grant that, if the notion of latency be received, the doctrine of steam, upon its being set free, receiving heat, and making it latent (the consequence of which absorption, we may suppose, would be the absence of the sensation), will be considered the probable one; but my explanation is founded upon the *improbability* of any kind of latent substance. I am, &c.,

J. ALEXANDER DAVIES.

STEAM FIRE ENGINES.

SIR,—There is an error in your last, which, as referring to an historical fact, permit me to correct. At page 52, it is stated that "in April, 1860, the London Fire Brigade agreed to hire on trial for twelve months a (steam) fire engine, constructed at the expense of Messrs. Shand and Mason. This steam fire-engine was found so serviceable that it was purchased, and several others were ordered, all of which are now in use by the London Fire Brigade."

The first steam fire-engine, so hired of Messrs. Shand and Mason, and made in conformity with their first patent, described in your pages, came out in July, 1860; its performances were *not* satisfactory, and in May, 1861 it was withdrawn and replaced by one on a different construction, in many respects like that Mr. Braithwaite brought out in 1830. A second, on this principle was supplied to the fire-brigade about the middle of last year, but a third was upon another and different construction, patented by Messrs. Shand and Mason in 1862. In Captain Shaw's report to the Committee of the London Fire Establishment, in December 1861, he stated that "the three land steam fire-engines recently ordered would be finished in about six weeks from that date." Various mishaps, however, prevented their anticipations from being realised, and two of them only have yet been delivered.

I am, &c.,

A CONSTANT READER.

London, January 27, 1862.

IRON WALLS AND THEIR ARMAMENT.

SIR,—During the last session of Parliament I availed myself of your permission to publish opinions on "Iron Walls" in the MECHANICS' MAGAZINE. Since then the subject has intensified in interest, and, has, it is no exaggeration to say, become a great national question. It is one which cannot be evaded or shelved. It will force itself into notice in its various aspects, naval, military, political, manufactural, and financial. Never was there a more stupendous question to be investigated and settled.

The approaching assembly of the council of the nation makes me desirous of again finding space in your columns for the expression of my views on the subject in question.

My opinions may be erroneous. If they are they share the fate of those of great authorities, military, engineering, and scientific, to whom the effects of guns on iron is a new study, of which they all have had to learn their A B C. But, by giving currency to opinions, and stating facts, I may help to provoke discussion, enlighten the public, and direct the attention of members of both houses to points which might otherwise escape notice.

There is, just now, an additional motive for fixing attention on the matters referred to. A number of experiments of an important and interesting character will, in the course of the next few months, take place at Shoeburyness. Of these it is desirable that the reports, if any are allowed to appear in newspapers, should be faithful and impartial, and not one-sided or garbled, such as the reports of target trials in the *Times* have almost invariably been. Hitherto, that journal, with a few exceptions, has had the monopoly of reporting experiments at Shoeburyness and Portsmouth, and in return for the easy access its reporters obtain to official sources, the leading journal pays the tribute of "quasi" official reports in terms calculated to support Government, and mystify or mislead the public.

If, on national grounds, the accounts of Admiralty and Ordnance doings and experiments were to be, or could be, a sealed book, I should be the last to give them publicity; but when it is notorious, on one hand, that foreign Governments, through their agents, who are always on the *qui vive*, are well informed on every move in our dockyards and arsenals; and, on the other hand, foreigners of all nations are allowed to inspect the works in progress in Government and private yards, and to witness all or any of the experiments—it would be affectation to require or maintain secresy. Under these circumstances, it is far better for the public interest that, instead of being dependent on the pretensious and oracular paragraphs of the *Times* for "naval and military intelligence," other sources should be opened. So far as I am able, I will contribute to elicit and give pnblicity to the truth, on the multitudinous questions embraced under the heading to this letter; comprising the manufacture and construction of armour plates, with their supports, fastenings, and backing, and the requirements of iron-cased ships and forts, guns and projectiles. These questions must be treated in a popular and somewhat desultory fashion, as they arise out of events which, from time to time, fix public attention.

IRON FORTIFICATIONS.

It is hardly possible to overrate the importance of iron fortifications, whether applied to ships or land works. They inaugurate a new system of naval and military tactics. The iron-clad man-of-war annihilates timber-built navies. Stone or brick fortifications are powerless where an invulnerable floating battery brings its guns to bear at short range.

Until the world was startled by the terrible and swift destruction hurled upon powerful first-class frigates from the iron sides of the "Merrimac," whilst she herself was proof against the heaviest missiles, it was not remembered that the effect of projectiles on ships or land forts results more from the hardness of the material of which the former are composed, than from the explosive force of the gun from which they are fired. It is iron against wood or masonry. The contest is unequal: iron has the best of it.

But when iron is opposed to iron, the conditions of the conflict are altered. Iron cannon balls, which cannot be resisted bp wood or masonry, will not so easily penetrate iron. I was, I believe, the first to point out the analogy between the penetration of iron plates with iron or steel projectiles, and the ordinary process of punching holes in boiler plates. It is an established law that a plate cannot be perforated by a punch less in diameter than the thickness of the plate. This law is confirmed by recent experiments at Shoeburyness. The Whitworth shot and shell of 7 in. diameter perforated 5½ in. plates, and those of 5½ in. diameter perforated 4½ in. plates, but could not pass through 5½ in. plates. And in the trial of an ordnance target constructed by Capt. Inglis, R.E., a 120-pounder Whitworth steel shot was smashed to atoms against an 8 in. plate.

Iron plates, therefore, of the required thickness and security, fastened to a structure of sufficient solidity, will be impenetrable by iron projectiles. Whatever may be the weight and velocity of the latter, their inferiority in volume and weight to the body opposed to them will, under the punching law, ensure their destruction; the material of both being of equal hardness. The value of hardness for penetrative effect is proved by the process of punching boiler plates. The punch being of steel, is easily forced through the iron plate. An iron punch could not be relied upon. The Whitworth projectiles, being of steel, penetrated iron plates which were impervious to iron shot.

Thickness of armour, which means weight of iron, has its limits for a ship in her carrying capacity. But for land fortifications there is no limit, therefore the application of iron to protect forts is a question of even greater importance than naval armour, because the former may be made completely invulnerable. There is a limit to the size of guns, but there is none to the weight of iron with which forts may be cased. In these two facts there is the germ of a new system of fortification for coast, harbour and river defences. Iron walls afloat must be opposed by iron walls on shore, for a squadron of efficient iron-clads would render the strongest stone batteries untenable.

But, in determining the value of iron for fortification, we are only on the threshold of the question. Iron, from its very nature—its hardness, its weight, and resistence to any agency but that of fire, or a metal harder than itself, is a material which demands skill, science, and costly appliances for its manipulation. The manufacture of armour plates, their size and form, and the mode of supporting and fastening them, are at present imperfectly understood, and require deep thought, profound research, and, above all, intelligent and numerous experiments.

These remarks are a brief *resume* of the points of view in which the question of iron fortifications is proposed to be considered under its different heads.

REED'S COMBUSTIBLE IRON-CLADS.

At the opening of Parliament the paramount question of national importance will be, "Are we to have an iron or a wooden navy?" As a natural seqnence, "wooden bottoms with iron top sides" will be discussed.

For this reason, I am induced to enter fully into the subject of Reed's iron-clads.

Next to invulnerability, the essential quality of an iron-mailed man-of-war is incombustibility. On more than one occasion I contended that the Reed plan did not fulfil either of those conditions. I described the incongruity and inefficiency of his proposed combination of iron and wood. These criticisms were met by denial of facts, and a refusal, on the pretended ground of a patriotic regard for national interests, to give explanations which might have satisfied the public if I was in error.

Some weeks ago an article in the MECHANICS' MAGAZINE, condemning the gun tower principle, exposed the blunder of the *Times* in asserting that broadside ships could not safely carry the heaviest guns. It also pointed out the advantage of placing great guns amidships, and showed that that arrangement was an essential part of Capt. Cole's system.

Simultaneously, the *Engineer*, in a notice of the same question, stamped with the authority of the clever secretary of the Institute of Naval Architects, put the case of a cupola ship armed with ten 12-ton guns, in five shields, the whole weighing 620 tons, and asked, "Who would not greatly prefer to incorporate 500 tons out of the 620 tons, in the *hull of the ship?*"

I took a different view, for whilst I joined in condemning the revolving tower, I preferred carrying the armour towards the centre of the vessel to protect the battery, to incorporating it in the hull. The arguments in favour of the former plan appeared to me conclusive, always bearing in mind that to carry it into effect the cupola is not indispensable. The writer in the *Engineer* made this question turn on the difference between *fixed* and *revolving* armour, whereas the real point at issue is the advantage of carrying the armour away from the side and nearer to the centre, an arrangement incompatible with the incorporation in the hull of a weight intended to fortify the battery; but an arrangement which can be accomplished on a plan affording the means of training the guns as effectually as in a rotary tower without its disadvantages.

In an article on iron-cased shipbuilding, which lately appeared in the *Standard*, Mr. Reed's system was reviewed. By a coincidence which can hardly be fortuitous, that article, as well as the article in the *Engineer*, possess, in common, one characteristic. Purporting to be an impartial review of a plan, as a public question, both are made the vehicle of extravagant and fulsome eulogiums of the designer.

Some time since I put our legistators on their guard as to the insidious nature of this novel scheme of naval construction. I warned the country to be vigilant, and now, again, I see the necessity of protesting against the expenditure of public money on a class of vessels which never can be effective iron-clads. In whatever way, under whatever design their real character may be disguised, they are nothing more than *wooden ships* partially protected with armour. It is asserted that these vessels are to be "coated all over (*as completely as any of our larger ships*) with 4½ in. armour." Will Mr. Reed come forward and corroborate this statement by declaring that his vessels will be coated with 4½ in. plates and 18 in. of teak backing, like the "Warrior," or with 5½ in. plates to 9 in. of teak, like the "Minatour," *in addition* to the ordinary frames and planking which form the hull of the ship? I throw down this challenge and await the answer. I do not wish to mislead the public, and shall be only too glad to be set right if in error. My only aim is to prevent mystification on a subject which is little understood; and, to justify the course I am taking, I avow my belief that the Reed combination is a contrivance to revert to the construction of wooden ships.

Mr. Reed, or his advocate, is a bold man to choose this as the auspicious moment for urging Government to construct a fleet of combustible "wooden bottoms." Four and a half inches of iron, on 18 in. of timber, is a "Warrior" target without the iron skin or frames. It is a body without a back-bone or ribs. Rigidity in the mass, and cohesive resistance in the parts, two properties which constitute the strength of iron ships, are wanting in the Reed plan. Those who have watched the experiments at Shoeburyness and Portsmouth know that 68-pounders, even in single shots, fired at such a target as the iron-plated hull of the "Enterprise" represents, will splinter the planks behind the area of impact; and, if fired in broadsides, at short range, will smash in the hull over large spaces. If Mr. Reed has any doubt on this point, let him go to Portsmouth and examine the sides of the hulks, which have served as targets for testing armour plates. The trials on the "Warrior" section proved that it was the rigid resistance locally, and all over the *iron hull*, which mainly obstructed penetration. The Reed belt, as it is affectedly called, is the "Warrior" broadside without the iron hull. What its fate will be under fire may be predicted. At long ranges, rifled 7 in. shot will perforate the sides through and through, and rifled shell will lodge their incendiary charge in the wood and set the ship on fire. At shorter range, 5 in. rifled shell will produce the same effects. A salvo of five or six guns, much more a concentrated broadside of 68-pounders, will crush in so large a portion of the hull that, if between wind and water, the ship will be in imminent danger of foundering. Will Mr. Reed, who taxes those who doubt the perfectness of his system with not understanding the subject, deny the probability of these results? Will the Admiralty shut their eyes to the palpable and fatal weakness of iron-clad sloops and corvettes with wooden bottoms?

To leave no room for doubt, there is a way of solving the vital question. Let a target, representing a section of the "Enterprise" "belt," be constructed and experimented upon. I earnestly press this recommendation on Government, and, until it is adopted, shall perseveringly, as I did last session with reference to the Spithead forts, invoke the interference of Parliament to demand a target trial, before the keel of another "wooden bottom" be laid down. Mr. Reed may be a first-rate naval architect. I have no desire to dispute his title to that distinction. But he is of the wood school, and he is working to aid the Controller's department in prolonging the reign of wood in the royal dockyards. Regarding that attempt as official blindness, convinced that, if not checked, it will lead to an enormous and wasteful outlay, and to national disgrace, if not loss of England's supremacy on the seas, I raise a warning voice, hoping it may find its echo in the House of Commons. These alone are the motives which guide me, not any personal feeling towards Mr. Reed, whose experience, as a designer and constructor of wooden ships, does not qualify him to form correct notions on armour plating, which is the province of the mechanical or military engineer.

From the foregoing observations, and the tenor of all I have written on this subject, it will be seen I do not assail the Reed iron-clad as regards the lines and form of the vessel, but as a powerless wooden cruiser, incapable of holding her own against an armour-plated iron ship. If its author will defend it on this ground, we shall have a fair issue. But in his ardent advocacy of his invention, he thinks only of the cruiser, and loses sight of the war ship. He is a naval constructor, but not a naval engineer.

Mr. Reed, it appears, thinks that in condemning his class of iron-clads I am dealing with a subject I do not understand, and affects to treat my opinions as unworthy of notice. This is a convenient way of ending a controversy, but it will not effect its object. The evasion of the question is unwise. No writer, who commits himself in the press to the condemnation or approval of any act or measure, on public grounds, supported by facts and arguments fairly stated, is unworthy of notice. The subject assailed, or its author, is brought to the bar of public opinion, and it is no answer to a charge to tax the assailant with ignorance. If no better reply is given, the natural inference is, that the ignorance is on the other side. The facts and arguments adduced, remaining unrefuted, may be regarded as true.

This subject will be resumed in another letter.

I am, &c.,
CIVILIAN.

STRENGTH OF IRON AND STEEL.

SIR,—I was vexed to find that by some unaccountable mistake you omitted the most practical, and therefore the most valuable, suggestion which my manuscript contained—namely, that of making use of the heat given out by the waste steam, in order to warm the iron tires of railway wheels during frosty weather.

At present the steam is allowed to pass uselessly into the air. I would propose that in frosty weather it be carried along in a jointed pipe underneath the carriages, with small holes through which it would escape towards the wheels, which, as they revolved, might receive and retain sufficient of the caloric to prevent their becoming brittle by the frost.

As I feel convinced, that by such arrangement many accidents might be avoided, and much injury to person and loss of life prevented, I should feel obliged by your giving this insertion in your valuable paper.

I am, &c.,
CHAS. BATHOE.

Gossip.

At the last meeting of the Liverpool Docks and Harbour Board, a communication from the secretary to Lloyd's was read, stating that, impressed with the necessity for some steps being taken to secure greater efficiency in the anchors and chain cables used in the merchant service in this country, they had passed a resolution in the latter part of last year to the effect, that to entitle a ship to be classed with the figure "1," her anchors should be proved to bear a strain equal to that known as the Admiralty test. That resolution, it was intimated, would come into operation on the 1st inst., and the committee had erected a proving house near the West India Docks at Poplar, and wished to know when the testing machine at Birkenhead would be ready for working. Referred to the Works Committee.

Mr. Donald Mc'Kay, in his report on the French navy, says the reason why iron war vessels are somewhat at a discount in France, is the insuperable difficulty of preventing their fouling. We have now another signal example of the same difficulty amongst ourselves:—The "Urgent," iron screw troopship, lately paid out of commission at Portsmouth, on her return from service in China, has been placed in dock at Portsmouth, and her bottom found to be covered with barnicles and other marine adhesions. The "Urgent" had been previously, during the term of her commission, carefully coated over her bottom with various so-called patent preservative compositions. The result has only been to coat her bottom with shell matter and weeds more plentifully than could possibly have been the case without them. We have before had occasion to remark on the apparent uselessness of these anti-fouling preparations, as illustrated by vessels docked at Portsmouth.

A general meeting of the Inventors' Institute will be held at the Polytechnic, Regent-street, on the evening of Monday, the 9th February next. We are informed that the Patent Law Committee of the Institute have completed their first report on the working of the laws relating to patents for inventions, which report will be published in the course of a few days. We understand also that arrangemants have been concluded for the use of rooms at the Polytechnic for the members' meetings, and we have no doubt that, under the management of its present council, which comprises many of our most noted inventors, and is presided over by that eminent man, Sir David Brewster, this institute will speedily take rank as one of the finest institutions in the kingdom. A large number of inventors and patentees have been already admitted to membership. The rights of inventors have always received our hearty support, and we shall have much pleasure in recording the success of the Inventor's Institute.

The following is the number of locomotives owned by each of the leading English railway undertakings. In the enumeration no account is taken of companies possessing less than fifty engines, and the figures, it should be stated, are brought down to the date of the latest return on the subject:—Bristol and Exeter, 60; Great Eastern, 328; Great Northern, 338; Great Western and South Wales, 413; Lancashire and Yorkshire, 363; London and North-Western, 972; London and South-Western, 177; London, Brighton, and South Coast, 145; Manchester, Sheffield, and Lincolnshire, 133; Midland, 475; North-Eastern, 446; North Union, 66; South-Eastern, 189; Stockton and Darlington, 151; West Midland, 104; Caledonian, 224; Edinburgh and Glasgow, 97; Glasgow and South-Western, 129; North British, 96; Scottish Central, 62; Scottish North-Eastern, 53; Great Southern and Western (Ireland), 92. The total number of locomotives at work in England and Wales at the date of the return was 4,956; in Scotland, 848; and in Ireland 352, making an aggregate of 6,156. Assuming that the average cost of each of those locomotives was £2,500, the capital invested in them would be no less than £15,390,000.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 1884, 1902.
BOILERS AND FURNACES, 1903, 1917.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1906, 1915, 1926.
SHIPS AND BOATS, including their fittings, 1881, 1895, 1918.
CULTIVATION OF THE SOIL, including agricultural implements and machines, 1878, 1921.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1869, 1874, 1929.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1870, 1872, 1877, 1886, 1889, 1890, 1901, 1907, 1909, 1911, 1913, 1916, 1922, 1923, 1927.
BUILDINGS AND BUILDING MATERIALS—*none.*
LIGHTING, HEATING, AND VENTILATING, 1876, 1880.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1873, 1897, 1899, 1900, 1930.
METALS, including apparatus for their manufacture, 1885, 1896, 1919.
CHEMISTRY AND PHOTOGRAPHY, 1871, 1883, 1888, 1891.
ELECTRICAL APPARATUS, 1879.
WARFARE, 1898, 1908, 1925.
LETTER-PRESS PRINTING, 1882.
MISCELLANEOUS, 1868, 1892, 1904, 1905, 1910, 1912, 1914, 1920, 1924, 1928.

1868. J. WITHAM. *Improvements in the apparatus used in working oil and other hydraulic presses.* Dated June 25, 1862.

Here, in constructing the pumps of hydraulic presses, the patentee makes them double action instead of single action; that is to say, he makes them to force liquid to the cylinders of the presses, both in the up and down strokes; and, as is usual, more especially for oil presses, he employs two pumps, one of small diameter to give the finishing pressure, and one of large diameter to rapidly bring up the ram of the press. The details of the invention are voluminous. *Patent completed.*

1869. G. TURNER. *Improvements in mincing apparatus, such improvements being also applicable to machines for grinding coffee and spices.* Dated June 25, 1862.

This consists in the application to such machines of a moveable end plate for forming a second bearing for the spindle of mincing machines of the ordinary construction, such plate being secured in its place by means of two screws or pins, one of which is inserted in the upper part of the casing of the machine, and the other in the lower part of such casing, slots being formed in the moveable end plate for embracing such screws or pins. An aperture is made in the moveable end plate to allow of the exit of the minced material, as it is forced out of the machine by the action of blades formed on the revolving spindle, which is in the ordinary way. *Patent completed.*

1870. J. David. *An improved dynamometer for ascertaining the relative strength and elasticity of various kinds of thread and ropes.* Dated June 25, 1862.

In carrying out this invention a spindle charged with the material to be tested, say thread, is placed vertically upon a needle of relative strength working upon a centre, from which needle proceeds an arm acting as a lever; the thread is passed from the apex of the spindle over the extremity of the arm, which, being drawn downwards, will remove the needle from its vertical to a horizontal position. At the lever extremity of the needle is attached a weight of relative power to the strength of the thread or other material; as the needle is acted upon, by the time it has reached its horizontal position, the lever end will have described the finish of a circle. A graduated quadrant, to scale, whether of pounds or of more or less weight, is placed between the needle and the lower end of the needle at the moment of the thread breaking, will be locked by a latch upon the teeth out on the outer side of the quadrant. The point where the needle stops is indicative of the amount of force the thread supported before breaking. To show the elasticity of the thread, one end is attached to the arm, as above, the other held in the hand; the thread is acted on by a lever describing a smaller quarter-circle, which, at the moment the thread breaks, the amount of its elongation is indicated by the difference between the scales of the two quadrated quadrants. *Patent abandoned.*

1871. W. Clark. *An improved frame for holding photographic pictures.* (A communication.) Dated June 25, 1862.

These improved frames consist essentially of grooved bars, in which the pictures slide, and in which they are held in position, as described. *Patent completed.*

1872. W. Clark. *Improvements in apparatus for raising the nap on cloth and other fabrics.* (A communication.) Dated June 25, 1862.

Here the inventor substitutes a metal comb for the vertical teazle. This comb is formed of metal plates having hooked teeth, and these plates are fixed to a frame in rows, one above the other, similarly to the pickers of the pickers of the teazle. The frames carrying the comb teeth may be of metal, or other substance. *Patent abandoned.*

1873. E. T. Hughes. *Improvements in regulating or moderating the movement of the keys of pianofortes.* (A communication.) Dated June 26, 1862.

In carrying out this invention, a spring is fixed by a screw at the back part of each key of the key board, and in order that the said spring shall not be turned aside either to the right or left, its moving extremity is curved, and traverses a lined hole in the key, which allows it to move as a piston, and without noise. Above the back part of the keys there is a bar extending the whole length of the key board from the bass to the treble. The top of the bar works upon pivots, so that it can be moved to and fro, and its lower surface rests upon the springs. When the bar rests upon the part of the springs most distant from their fixed ends, a slight resistance is given to each key, which resistance is increased in a progressive manner as the bar is made to recede towards the fixed ends of the springs. The said bar is moved to and fro, as required, by a rack gearing into the teeth of a toothed segment fixed to the bar, motion being given to the rack by a screw upon a rod, the plain part of which works in a collar, and extends to the front, and has at its extreme end a socket for a key, by which the screw may be turned. Attached to the rack, or to the bar, there is a plate of metal, or other material, in connection with a scale, or gauge, placed in sight, at the front part, for the purpose of indicating the position of the bar, and the resistance given to the keys. Thus, by turning the screw, so as to move the rack backwards, resistance is given to the keys of the key board, and, by reversing the motion of the screw, the resistance is diminished. *Patent abandoned.*

1874. G. Peterson. *Improvements in apparatus for ascertaining the quantity and strength of spirits or other products obtained by the process of distillation.* (A communication.) Dated June 26, 1862.

We cannot here quote the details of this invention. *Patent completed.*

1875. S. R. Trebutt. *Certain improvements in the manufacture of soap and soda and other material employed for the purpose of washing and cleansing.* Dated June 26, 1862.

This invention consists in the novel employment and use of such oils or spirituous extracts, petroleum, camphine, rock oil, paraffin, naptha, and other such similar oils and spirits procured from wood, and progressing detergent properties. The oils or spirits are to be mixed and incorporated with the washing material in any required proportions to increase the cleansing or detergent powers thereof. *Patent completed.*

1876. J. Parkes. *Improvements in gas lanterns.* Dated June 26, 1862.

This invention relates to that class of lantern suitable for suspension in railway stations and other public places, and are of a globular form; the framework consists of a series of segmental ribs, to which the glass is fitted and makes up the globular form, each piece being of the section of a sphere. The patentee employs three rings in the frame—two small ones, one each at top and bottom, and one large one at the middle or equatorial line. The small rings he makes of a thin strip of metal presenting the edge to the light, and consequently to throw little or no shadow. The middle bead is unlike that in ordinary use, being narrow and without openings—the only openings in the lamp being above and below the one at the bottom for admission of the air, and the other at the top for the escape. The section of metal of which he forms the segmental ribs, and the large ring, consists of a flat strip with a hollow head united thereto on the outside, the whole being kept as narrow as consistent with the strength necessary. He supports this lamp with three rods united to the middle bead, and meeting at top in a single pendent arm or branch; or they may be otherwise supported. From the absence of apertures in the middle bead, and the disposition of the metal in its upper and lower rings and ribs, which are few in number, comparatively little surface is presented to intercept the radiation of light, and, consequently, little or no shadow is thrown. The gas duct passes down one of the arms to the mid ring, and there enters the globe, and descends to a suitable position for the jet. The stop cock he prefers to place immediately under the jet, and concentric with the lower opening in the lamp, the elbow being formed with a stop cock in which the gas passage emerges at one end of the axis, with a view to that object. The parts of the frame are united by soldering, brazing, or otherwise, and the glass, which is inside the frame, is fixed by means of metal strips coinciding with the ribs and large middle ring, and fixed thereto inside and upon the edges of the glass; or the glass may be fixed with putty and otherwise in the ordinary manner of fixing the glass in similar kinds of lamps. *Patent completed.*

1877. J. B. Coquatrix. *Improvements in weaving carpets, tapestry, and similar fabrics, and in apparatus for the same.* Dated June 26, 1862.

This invention consists in the passing of the warp threads through two reeds fixed opposite each other in the batten of the loom. By using two reeds instead of one—as is usual in weaving all kinds of fabrics—the patentee is enabled to use a much larger number of threads, and also of producing, by an arrangement of the warp, a tapestry stitch which has, hitherto, only been effected by hand. The stitch of which the improved carpets are made is that termed Gobelin stitch or fine tapestry, done with a needle. He thus obtains a much more regular and stronger work than that done by hand. The designs which he weaves at the present time are suitable for arm and other chairs. *Patent completed.*

1878. J. Martin. *Improvements in reaping and mowing machines.* Dated June 26, 1862.

This relates to improvements in reaping and mowing machines, and consists in accumulating the motive power in one or more springs, by which means the cutters are caused to operate with equal speed and effect, whatever may be the rate of speed at which the machine is driven. *Patent abandoned.*

1879. J. H. Johnson. *Improvements in the construction of electric-voltaic plate 'work. for medical and other purposes.* (A communication.) Dated June 26, 1862.

This invention relates to a peculiar construction and arrangement of articulated or flexible electro-voltaic plate work, intended for the cure of certain bodily complaints, and applicable in various forms, suitable to be worn about the person, but more particularly in the form of an inner sole to be worn inside boots or shoes. The essential feature of this invention is the forming of articulated electro-voltaic plate work in various sections throughout the whole major portion of its area, by using two or more tiers of negative plates in preference to one, and interposing between such plates a series of positive plates, or by using two or more tiers of positive plates, and interposing between a series of negative plates. The upper and lower plates should be so divided and kept separate longitudinally and transversely as to establish a multiplicity of negatives and positives, with their contiguous edges exposed and breaking contact. The several sections of the positive and negative plates are connected or hinged together by a flexible insulating strip or strips of india-rubber, or other suitable material, united to the sectional plates by metallic or other eyelets. But in order to give a more united character to the whole, and facilitate the manufacture, it is preferred to connect the sections of plates by a single insulating strip made with perforations or openings therein, so as to be of a skeleton form, and admit of the positive and negative plates, or rather those sections which lie one under the other coming in contact, and establishing electrical action between or by the said plates or plate sections. *Patent completed.*

1880. J. H. Johnson. *Improvements in fluids to be used for illuminating purposes.* (A communication.) Dated June 26, 1862.

This consists in the production of a new illuminating fluid, consisting of a combination of a fusel oil, petroleum, paraffin, or coal oil and alcohol, or of such alcohol as is known as methylated spirit. The proportions, as at present found suitable, are four quartz of fusel oil, one quart of refined petroleum, paraffin, or coal oil, and about a pint of alcohol, or of methylated spirit. The fusel oil before being mixed with the other oils, is purified or cleansed by being washed with water; after the water which has been used for this washing process is drawn off, the petroleum, paraffin, or coal oil, is added to it, and the alcohol being then added, produces a chemical combination, and a fluid fit for burning purposes. *Patent abandoned.*

1881. A. Anderson. *Improvements in apparatus for steering ships and other vessels.* Dated June 27, 1862.

Here the rudder head is furnished with a tiller or lever arm, to which the ends of ropes or chains are attached, which pass in opposite directions around blocks or pulleys, carried by arms or projections fixed to the deck or other part of the vessel. From the sheaves or blocks, the ropes or chains pass to and around a grooved drum or barrel, to which the other ends of the ropes or chains are fixed. The grooved drum or barrel is carried by a vertical (or it may be in any other position) shaft or axis, supported in fixed bearings, and on the upper end of this axis a toothed bevel wheel is fixed, which takes into, and is driven by, a bevel pinion fixed on a horizontal axis, upon which the hand or steering wheel is fixed, and by which motion is communicated to the rudder when required. *Patent abandoned.*

1882. J. Watson. *Printing sheets of paper from letter-press forms, stereotype blocks, and wood engravings.* Dated June 27, 1862.

This consists in the general design of the mechanism and arrangement of the parts of the apparatus by which the following advantages are obtained, that is to say:—1, Printing from both sides of the cylinder, taking one impression from the letter-press forms, blocks, and wood engravings, as they pass under the said cylinder from left to right, and another as they return from right to left, and so on continuously. 2, By so constructing the cylinder and feed and delivery rollers and apparatus in connection therewith, that the whole can be instantly lifted by a hand lever, moved to the right or left, so as to cause the paper to pass through the machine without taking an impression, in the event of its becoming deranged in the laying-on operation. 3, In giving a reciprocating motion to the table carrying the letter-press forms, blocks, &c., and inking boards, by the running gear, without any additional reversing mechanism. 4, Causing the said apparatus to start the sheets upon the laying-on boards at each return of the tables from the left to right, and *vice versa*, by adjusting spring catches and levers. 5, By such adjustment adapting the same cylinder and table for printing sheets of various sizes. *Patent completed.*

1883. C. Cockrane. *Improvements in the manufacture of aluminate of soda and potash.* Dated June 27, 1862.

Here slags obtained from the blast furnace used in the manufacture of iron, are reduced to a powdery form by any of the well-known methods, the best being first to run the slag whilst in a molten state direct from the blast furnace into water. 2, To dry the wet friable slag thus obtained. And, 3, To crush it when dry between a pair of cylinder rollers. The dry, crushed slag is now intimately mixed with a salt of soda or potash, in the proportions of one part of the dried salt (the carbonate of soda or potash being preferred), to four parts by weight of slag, containing about 23 per cent. of alumina. These proportions, however, may be varied, and should vary with the percentage of alumina in the slag. The mixture thus obtained is next thrown upon the hearth of an ordinary reverberatory, or other suitable furnace, in quantities varying of course with the size of the furnace—say, from four to seven cwts. a charge—and these subjected to a temperature somewhat above cherry red heat, but falling short of actual fusion of the ingredients in the furnace, which are to be repeatedly stirred by the workman, so as constantly to expose fresh surfaces to the action of the heat. The completion of the process is ascertained by removing, from time to time, a small quantity of the contents of the furnace and testing it with acid, using by preference hydro-chloric acid. When effervescence ceases on the addition thereof, the materials are drawn from the furnace, and next subjected to the well-known process of lixiviation, by which the soluble ingredients of the products of the furnace, namely, the aluminate of soda or potash, is dissolved out; the liquor containing the salt is then decanted into an evaporating pan, which may be either heated from above or below, and the aluminate of soda or potash obtained therefrom by evaporation. *Patent completed.*

1884. E. Hunt and H. D. Pochin. *An improved condensing apparatus.* Dated June 27, 1862.

This consists in an improvement in separating and depositing resinous or fatty matter, which has, for the purpose of distillation, been converted into a state of vapour by an admixture of steam. This is effected by disposing in the interior of a metal box, furnished with metal partitions, and surrounded by a water or steam-tight jacket, a series of perforated copper plates, against which the admixture of steam and such resinous or fatty matters is made successively to impinge, and in which the resinous or fatty matters are arrested, while the steam is allowed to pass out of the condenser. *Patent completed.*

1885. C. Cockrane. *Improvements in the manufacture of iron.* Dated June 27, 1862.

Here aluminate of soda or of potash is used in order to purify and improve the manufacture of iron. It is preferred that the aluminate of soda or potash should be to and mixed with iron when in the melted state, and when the iron is about to be puddled; but the application of the aluminate may be at a different part of the process of the manufacture of iron to that above named. *Patent abandoned.*

1886. J. Lord and J. Brown. *Certain improvements in power looms for weaving.* Dated June 27, 1862.

This consists in a method of effecting the stoppage of the loom when the shuttle does not enter the shuttle box. Upon the ordinary stop rod of the loom the inventors fix a vertical rod projecting downwards, and forming a bell crank lever with the stop rod tongue; and upon this rod a spring is fixed, which is acted upon by a stud on the crank arm at each beat up; also on the rod and beneath this spring a projecting finger is arranged so as to come under a bowl on the framing for the purpose of holding the stop rod tongue out of contact with the frog during the traverse of the shuttle. When the shuttle enters the boxes as required, the spring yields to the stud on the crank arm; but when the shuttle omits to enter the box at the proper time, the back finger on the stop rod, not being sustained by the swell of the shuttle, is at liberty to fall inwards, so that, when the stud on the crank arm lifts the spring at the next beat, the vertical rod is moved by the spring, and turns the stop rod sufficiently to throw the stop rod tongue into contact with the frog, thereby effecting the stoppage of the loom. *Patent abandoned.*

1888. R. A. Brooman. *A method or methods of preparing paper for the reception of photographic pictures, or impressions may be transferred to and fixed on wood, porcelain, and other surfaces.* (A communication). Dated June 27, 1862.

The details of this invention are too voluminious to be quoted here. *Patent completed.*

1889. A. H. Martin. *Improvements in means or apparatus employed in weaving.* Dated Jnne 27, 1862.

The object here is to obtain increased uniformity or evenness in the winding on or taking up of the cloth. For this purpose the workbeam is borne with the surface of the cloth thereon to the surface of the top beam, or first drawing roller, by weighted or other suitable pressure, and the two beams are geared together by frictional gear, adapted to admit of slip as the diameter of the cloth beam increases by the quantity os cloth wonnd thereon. And to compensate for the consequent difference of distance of the axe of these two rollers or beams, the patentee forms the teeth of the gear of length to admit of such increase of distance without the teeth of the respective wheels separating one from the other. *Patent completed.*

1890. J. Holden. *Improvements in means or apparatus for preparing and combing wool and other fibrous materials.* Dated June 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1891. A. A. Croll. *Improvements in the treatment of ammoniacal liquor of gasworks.* Dated June 27, 1862.

This invention has for its object economy in the treatment of ammoniacal liquor of gasworks when obtaining salts of ammonia; as also the avoidance, or great mitigation, of the inconvenience and annoyance arising from the treatment of such liquor. Steam, from a suitable boiler, is conveyed into ammoniacal liquor contained in a suitable closed chamber, and the combined vapour and steam resulting are conveyed from the upper part of this chamber into other ammoniacal liquor contained in another closed chamber, placed somewhat higher than the preceding, in order that, as the ammoniacal liquor in the previous chamber becomes spent, it may be supplied from the second, and, if desired, other number of such ammoniacal chambers may be employed. From the last ammoniacal chamber, the vapour resulting, combined with particles of steam, are conveyed into a closed compartment, or chamber, of a vessel containing acid adapted to the salt of ammonia desired to be obtained. Thus, supposing the salt desired is sulphate of ammonia, then this last chamber will contain sulphuric acid, and it is, at its upper part, divided into two compartments, one open at the top, the other closed by a cover, and a partition dipping below the surface of the acid liquid therein, and below the mouth of the pipe conveying the vapour and steam thereto from the last ammoniacal chamber. Any vapour arising from the closed compartment of this vessel is conveyed into similar acid in another closed chamber used as a reservoir. From the upper part of this last closed chamber the sulphuretted hydrogen liberated is conveyed to the furnace supplying a vitriol chamber. *Patent completed.*

1892. D. L. **BANKS.** *A method of constructing a portable covered coffer-dam, or apparatus for facilitating operations under the water, in the water, or out of the water, and apparatus connected therewith.* Dated June 27, 1862.

We cannot here give space to the voluminous details of this invention. *Patent abandoned.*

1893. D. L. **BANKS.** *A method of constructing a portable sectional dry dock, and apparatus connected theirein.* Dated June 27, 1862.

We cannot here give space to the details of this invention. *Patent abandoned.*

1895. T. **KING** and J. **KING.** *Improvements in agricultural machines.* Dated June 28, 1862.

This consists, 1, Of an agricultural machine for loosening the soil (it may be after it has been broken up by ploughing or by a scuffle), and bringing to the top of the soil whatever rubbish, such as twitch or weeds, the soil may contain. The said machine is constructed essentially as follows:—Upon a frame mounted on travelling wheels a revolving barrel or roller is supported, to which a horizontal revolving motion is given by the travelling wheels, the said barrel or roller being geared to the travelling wheels by toothed wheels or other gearing. On the cylinder surface of the said barrel or roller, spikes or tangs are fixed in a radial direction. As the machine is drawn over the land, the barrel or roller revolves, and the spikes or tangs enter the soil nearly to the depth to which it had been previously broken up by the plough and scuffle. The said spikes or tangs in passing through the soil lessen it, and on rising out of it, bring out the twitch and weeds, and throw them on the surface of the soil, from which they may be removed, or where they may be left to perish. 2, In applying a moveable collar roller to the prongs of scuffles or the coulters or other like parts of agricultural machines. The said collar or roller is applied to or fixed on the prong or coulter, and turns on a vertical axis. The said collar or roller prevents the prong or coulter carrying with it soil, or anything which impedes its proper working, and it is very useful on clay soils. *Patent abandoned.*

1896. C. **BESLAY.** *Improvements in galvanizing or coating metals by electro-chemical agency.* Dated June 28, 1862.

This relates to improvements upon a former patent, granted to the present patentee, Jan. 12, 1859 (No. 103), and consists in the galvanization of metals, more especially cast or other iron and steel, by indirect means at the ordinary temperature with non-concentrated solutions, which he terms galvanization in a cold state. *Patent completed.*

1897. G. H. **HULSKAMP.** *Improvements in pianofortes.* Dated June 28, 1862

The patentee states that some degree of tension in the sounding board produces a striking effect upon the quality and volume of its tone, and the best effects are produced when some relation exists between the tension of the strings and the strain upon the board; and this invention consists in applying this principle to pianofortes of different kinds. The patentee can dispense entirely with the iron bars usually placed above the strings in grand pianos, but he prefers to cover the wrest and hitch plates with a thin solid metal frame. The strain of the strings on one side of the frame is counteracted by an unequal strain of the sounding board on the other. An equilibrium is maintained between the two. Any excess or variation of the tension on one side is, in a measure, communicated to the other, and a proper relation between the two sustained. The invention is not fully described apart from the drawings. *Patent completed.*

1898. J. **GARNIER.** *Improvements in ordnance and in projectiles.* Dated June 28, 1862.

The documents relating to this invention cannot at present be seen, an extension of time for filing the final specification having been petitioned for.

1899. G. W. **BELDING.** *An improved flexible spring cloth or fabric adapted for the manufacture of ladies' skirts.* Dated June 28, 1862.

In producing this cloth ebonite is combined with the ordinary materials of which cloth is composed, either in the process of weaving or felting, or by attaching strands of ebonite to manufactured cloth by sewing. *Patent abandoned.*

1900. C. **CALLEBANT.** *Certain improvements in sewing machines.* Dated June 28, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1901. J. **TATHAM.** *Improvements in machinery or apparatus for preparing, spinning, doubling, and winding cotton, wool, and other fibrous materials.* Dated June 28, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1902. J. **PETRIE.** *Improvements in slide valves for steam engines.* Dated June 28, 1862.

This invention consists in forming the slide valves of steam engines with cylindrical faces, so that they may be capable of turning upon centres of motion; and this turning the inventor effects by means of tappets or other ordinary apparatus connected to a moving part of the engine. In addition to this rotatory motion the valves slide as usual; but by the first-described arrangement the steam may be cut off at any part of the stroke. The valves may constitute a portion or the whole of a cylinder, and in the latter case he avails himself of the back part thereof for packing, whereby a portion of the steam pressure is removed. *Patent abandoned.*

1903. J. **WEBSTER.** *Improvements in the means of protecting steam-boilers from incrustation.* Dated June 28, 1862.

This invention consists in causing the earthy and saline matters which heretofore have been deposited on the boiler to be precipitated by electric currents on another surface. One mode of carrying out the said invention is to set up an electric action by the contact of two metallic surfaces. Thus, in an ordinary steam-boiler, the inventor places in contact with each other a sheet of copper, and a sheet of zinc (these he mentions as the metals he believes to be most suitable); these he immerses in the water in the boiler, and he insulates them, as far as metallic contact is concerned, from the boiler. It will then be found that all the earthy and saline matters held in solution in the water will be deposited on the said copper plate or plates, which can from time to time be taken out of the boiler for the purpose of cleansing. The entire interior surface of the boiler will thus be preserved clean. *Patent abandoned.*

1904. N. **THOMPSON.** *Improvements in apparatus for stopping bottles, jars, and other vessels, and in instruments for applying and removing such stopping apparatus.* Dated June 28, 1862.

For the purpose of stopping bottles, jars, and other vessels, the inventor employs a cover or stopper of suitable rigid and non-porous material, which enters into the neck of the bottle or jar, and fits on to or into a seat therein, an elastic material being interposed between the two surfaces. Connected with the top of the cover or stopper, but so as to be capable of turning freely, is a screw which passes through an outer lid; this also fits into the neck of the bottle or jar, and it is notched at its periphery at three, four, or other convenient number of points, and the interior of the neck of the bottle or jar has corresponding projections upon it, so that the lid can only be dropped into its place when turned into such a position that the notches therein correspond with the said projections, when it can be turned round, and then, by rotating the screw, the lower can or stopper is forced down, and a tight joint made. There are recesses in the rim of the upper lid into which the projections in the neck of the bottle or jar drop when the lower cover or stopper is forced down by the screw, so that the lid becomes secured, and cannot be turned until the screw is again slacked; a key is employed to turn the screw, which may, if desired, be protected by a seal or capsule or otherwise. *Patent abandoned.*

1905. J. **WALL** and T. **DODD.** *Improvements in taps for controlling the flow or passage of fluids.* Dated June 30, 1860.

The patentees claim, firstly, the construction of taps or cocks with one valve working between two seatings, substantially in the manner described. Secondly, the construction of taps or cocks with a thimble or cap, having apertures therein for the passage of the fluid, over the internal surfaces of which apertures the whole or part of the outer surface of the valve must travel either in opening or closing, substantially in the manner described. *Patent completed.*

1906. W. **THOMAS.** *Improvements in the running gear of four-wheeled carriages.* Dated June 30, 1862.

The body of the omnibus—which may be made of any convenient form—is supported by springs of any known kind, resting on, suspended from, or in any way attached to the axles, and the carriage parts are fitted in the ordinary manner. On the axle, near the inner ends of the naves of every wheel, are secured brackets which carry studs, pins, or bolts for receiving the ends of the tension rods of the equirotal lock arrangement or system. These rods are made preferably of metal, and are carved diagonally from the near fore to the off hind wheel, and from the off fore to the near hind wheel. To prevent friction and flattening of such tension rods, the patentee uses four or more friction rollers, so arranged in a frame or bracket that the said rods shall be kept a sufficient distance from each other, and the friction reduced to a minimum, both in turning, and during the shaking and jolting in straight running. The gear to which the pole of the omnibus is fixed, as well as the gear permitting quick turnings to be made, is the same at both ends, and the main parts of each end consist of four metal tension rods, two or more elliptical shaped or otherwise formed metal bars, rods, or springs, a futchel piece, and a curvilinear metal forging, with a bracket or brackets and friction roller or rollers thereon. All the tension rods are jointed on studs, pins, or bolts, secured by brackets or otherwise to the axle, two at or near each end of the same, and close to the inner ends of the naves of the wheel. One of these tension rods at each side is carried forward to or near to the front or end of the omnibus, and is there coupled by a joint to two or more elliptical or other metal bars, rods, or springs. The other two tension rods are carried forward, and almost meet near the centre of the said elliptical or other bars, rods, or springs, and the futchel piece or socket for the pole is secured in the same position; that is, equi-distant from the ends of the elliptical or other bars, rods, or springs. The bracket or brackets is or are secured or jointed to the said futchel piece, to the elliptical or other bars, rods, or springs, or to both or either of them, and pass and encompass a curvilinear or other suitably formed metal forging principally in a horizontal position, made fast by flanges or otherwise to the bottom of the body of the omnibus. This curvilinear piece, which carries the whole of the fore draught gear, allows the bracket or brackets, and the elliptical or other bars, rods, or springs, as well as the tension rods, to travel or move laterally a sufficient distance for quick turning of the omnibus, friction being diminished by a roller or rollers in the ends of the said bracket or brackets. A further improvement in running gear consists in making the naves of the wheels of the kind known as the "patent mail wheel" of iron, instead of iron and wood combined; the sockets for the wooden spokes being cast or formed in the nave. *Patent completed.*

1907. J. **HARTSHORN.** *Improvements in the manufacture of lace.* Dated June 30, 1862.

One part of these improvements relates to employing extra threads, operated by bottom guide bars (when two sets of guide bars are used), in combination with extra stump bars or spaces for such threads, by which such threads so operated may at times be used to produce looped, purl, or open edges to holes, and at other times be used to produce, increase in substance, or other effects in or upon the body of the fabric. The tension on such threads is regulated as required. Another part of these improvements relates to producing in machine-made lace holes inclined or at angles to the selvage of the fabric, by the working of certain of the warp threads operated by figuring or embroidering bars, and supplied from the main beam, such threads being caused to loop with certain of the bobbin threads at the whole or holes to be diverted or drawn, and then to traverse in and form part of the body of the fabric to a distance sufficient for the required tension. *Patent abandoned.*

1908. A. **BYRNE.** *Improvements in breech loading fire-arms.* Dated June 30, 1862.

This invention is carried into effect as follows:—About four inches in length of the breech end of the barrel is bored out somewhat larger than the principal part thereof. At the junction of the two sizes of bore a conical seating is formed for the purpose of receiving a plug or stopper. Immediately before such seating is placed the ordinary percussion nipple, and behind the same an opening is made by cutting a gap on the top side about three inches in length, and about one third of the diameter of that part of the barrel in depth, leaving about one inch in length behind the opening to receive the breech piece, and form an abutment for the plug or stopper. The sides of the opening are cut away to the full width of the bore, and grooved for a purpose hereinafter stated. A plug or stopper about one inch in length is fitted to the bore within the opening, free to slide the full length thereof, and shaped to fit the conical seating air tight when pushed forward. One part of a hinge is projected on the top side of such plug (behind the conical part) unto which is attached a flap or cover, so shaped as to close the opening, and to fill up that part of the bore between the plug and the back end thereof, thereby completing an abutment for the plug or stopper (quite independent of strain upon the hinge pin) when the flap is shut down. A guard piece is fitted to the plug, and made to slide in the grooves before mentioned to keep the same from rising when drawn back, and admit a cartridge. The flap is fitted with a self-closing spring bolt, such bolt being acted upon by a cranked spindle (or its equivalent), with an arm or lever attached, and so arranged as to withdraw the bolt from the fastened position when the lever is lifted up, and to close and securely fasten the same when the lever is let down. In the latter position only is it possible to get the hammer to the full bent ready for firing. These parts are altogether so arranged that, by one act, the bolt is withdrawn from its fastened position, the flap opened, and the plug or stopper drawn to the back end of the opening, making room in front to admit a cartridge. And when the cartridge is inserted by one act, the plug is pushed up to the seating, carrying the cartridge before it into the barrel, and the lever shut down and securely fastened safe and ready for firing. *Patent abandoned.*

1909. W. E. **GEDGE.** *Improvements in looms for weaving.* (A communication.) Dated June 30, 1862.

This invention consists of improvements in that part of a loom known as the cording or tie up machine or apparatus, and permits working with as many lames as the loom will carry, and with a repetition of, say, thirty treadles. The object of this tie up machine is, therefore, to give the facility of making on power looms figured fabrics which have hitherto only been made by the hand loom. *Patent abandoned.*

1910. W. F. **MURRAY.** *Improvements in the manufacture of stoneware bottles.* Dated June 30, 1862.

According to the improved system or mode of manufacture the material of which the bottle is composed is formed with an inwardly projecting part a short distance below the mouth. This projection forms a smooth swell or bulge, which facilitates driving of the cork into the bottle, and grips it at the central part in such manner as to effectually exclude air, at the same time the expansion of the cork below the projecting part of the neck prevents the cork from becoming loose, or being driven out by accident, or by the expansion of the fluids. *Patent abandoned.*

1911. W. E. **NEWTON.** *Improved apparatus for picking or gathering cotton.* (A communication.) Dated June 30, 1862.

This invention cannot be described apart from the drawings. *Patent completed.*

1912. W. **EASTON** and G. **DOUKIN.** *Improvements in lears or annealing chambers, and apparatus used in annealing glass.* Dated June 30, 1862..

Heretofore lears or annealing chambers have, in some cases, been made in such manner that the apparatus or beds on which the glass is piled or placed have been moved horizontally through a considerable length of a chamber or lear, wherein the heat has progressively decreased. Now, according to this invention, a lear or chamber is constructed with an ascending and a descending limb, which are connected at their upper ends. The succeeding beds or surfaces on which the glass is placed or piled are raised in the ascending limb, and having arrived at the upper part of the ascending limb they pass to and then down the descending limb of the lear or annealing chamber. The ascending limb of the lea is heated, and the requisite heating of the glass takes place therein, and in the top part of the chamber. The temperature of the descending limb decreases from the upper part downwards. It is preferred that the series of beds or surfaces on which the glass is placed or piled should be connected together, in order that those in the ascending limb may be counterbalanced by those in the decending limb of the lear or annealing chamber. The two limbs are connected also at their lower ends, and provision is there made for the surfaces or beds as they are unloaded to pass readily from the descending limb into the lower part of the ascending limb of the lear or annealing chamber, in order to their being again loaded before they again ascend in the ascending limb. It is not, however, essential that the several beds or surfaces on which the glass is placed or piled should be connected together, as provision may be otherwise made for raising and lowering them in the ascending and descending limbs of the lear or annealing chamber respectively. *Patent completed.*

1913. T. **Parker.** *Improvements in tinting or dyeing fabrics composed of mixed animal and vegetable fibres.* Dated June 30, 1862.

In carrying out this invention, fabrics which are composed of mixed animal and vegetable fibres, such as those woven with cotton warp, wefted with wool, or with alpaca, or with other animal fibres, and also other fabrics wherein are used a combination of animal and vegetable fibres, are treated in the following manner:—The fabrics are first well scoured and thoroughly cleaased; twey are then, in a moist state, introduced into and stoved into a sulphur stove, the fabrics being kept open or extended whilst in the stove. The fabrics are then taken from the stove, and without extracting or removing the sulphur they are caused to pass through water, and then through the dye liquor. In performing this process it is important that the fabric should be kept open and passed horizontally through water. It is subjected to pressing rollers as it comes out of the water. It is also important thai it should then be passed in an open state horizontally through the dye liquor, and be pressed between pressing rollers as it comes from such liquor; the fabric is then to be dried. By these means not only will the fabric be very evenly tinted, but at the same time it will have a high finish communicated to it, the animal and vegetable substances in the fabric being similarly tinted or dyed. *Patent completed.*

1914. J. **Parkinson** and J. **Marsland.** *Improvements in apparatus for regulating the flow and pressure of steam and other fluids.* Dated July 1, 1862.

This improved apparatus is particularly applicable as a reducing valve, that is to say, as a valve for reducing the pressure of steam from that in the boiler or other receptacle to the pressure required for heating or other purposes. The apparatus consists of a hollow piston or plunger, open below, which fits in a cylinder, corresponding holes being made in both; the cylinder is secured in a box or casing furnished with inlet and outlet pipes or passages. A spindle from the hollow piston or plunger passes through the cylinder and casing, and it is weighted according to the difference in the pressure between the in-coming and outgoing steam or other liquid. When the improved apparatus is used as a throttle valve, the spindle of the piston or plunger is connected to the governor, so that when the governor-balls expand or collapse the piston or plunger is raised or lowered in the cylinder, thereby contracting or expanding the passage for the steam through the holes in the piston or plunger and the cylinder. In this case the piston or plunger, instead of being closed above, is left open, and the spindle is connected to a cross bar, and passes through a stuffing-box in the casing. *Patent abandoned.*

1915. E. F. **Prentiss.** *Improvements applicable to omnibuses and other vehicles.* Dated July 1, 1862.

This invention relates to a peculiar arrangement and mode of applying the running gear to four-wheeled carriages, to facilitate their turning, and that they may be driven either end foremost. And also to a peculiar construction of light body for passenger carriages, which it is proposed to call the "skeleton" or "spider" chariot. The first part of these improvements consists in constructing and fitting both the front and hinder axletrees of four-wheeled vehicles in sucn a way that they will both turn horizontally round on their vertical axle pins (or "perch bolts") a given distance, and in connecting the two axletrees together by two crossed connecting rods. One of these rods the patentee joints to the front axletree near the nave of the near wheel, and carries it across to the hinder axletree, and joints it thereto near the inner side of the off wheel, and the other rod he joints to the front axle near the off wheel, and which he also extends to the hinder axle, to which he joints it, in like manner, near the inner side of the near wheel. By this arrangement, it will be readily seen that, if the leading wheels are turned towards the left, the two wheels on the left side of the carriage will be brought towards and at an angle to each other, and that the two wheels on the right side of the carriage will be proportionately separated from each other, when the carriage can be readily turned toward the left; and, by turning the leading axle toward the right, the reverse motion will take place in the wheels, and the carriage can be turned in the opposite direction. The second part of the invention relates to the construction of light carriage bodies for open passenger vehicles, and consists in a light parallelogramical frame of wood, angle iron, or other suitable material, between and from the longitudinal sides of which spring a number of light arched spanners of wood, fitted with metal tie rods, or they may be constructed entirely of metal. On the crown of the arched spanners he constructs a vertical longitudinal railed, or other suitably shaped back, for longitudinal seats, fitted on each side thereof. The seats, he prefers, should be cane-seated frames, fitted with loose cushions. The foot rests, and the stages at each end of the body he proposes to form of light open grating framework, and to surround the whole with a light rail, or light open frames, or closed panelwork, except at the openings left for ingress and egress. He further proposes to erect two or more standards, extending above the centre back rail, for supporting a suitable double hood, which can be let down at both or either side of the carriage. *Patent completed.*

1916. E. **Pourpoint.** *An improved wool washing machine.* Dated July 1, 1862.

This improved machine is composed of a wooden framing, on which is suspended a basin pierced with holes, and four cast-iron brackets with copper or brass bearings receive two shafts of square iron, but with the extremities rounded so as to be placed on the bearings. These shafts carry two pulleys, one fast and one loose (or a crank may be substituted when hand power only is at command). The fixed pulley on each shaft causes the two shafts to work together by the aid of a cross band, so that the movement of the four hollow copper arms (by which the wool is to be kept in agitation) are opposed to each other in such wise that the wool, which is driven by the arms on the right, is pushed back by those on the left, and is thus kept uniformly thick in the basin. Each end of these arms forms a curve, so as to slide on the wool in displacing it, without, however, lifting it out of the water. These arms are of hollow copper, rather than of solid iron, in order that they may work more lightly, that the wool may not be pressed or pulled, and because the scouring, which is usually effected with soda or acids, would oxydize iron and damage the wool. These four arms are bolted crosswise, two on each shaft. The bottom of the said machine is of non-oxydisable metal, and is pierced with small holes for the escape of the dirt from the wool. It is fixed on two iron bars, flat at the edge from end to end, and is supported by bolts at each corner of the framing. A pipe is placed in the interior, and from it pure water is poured on the wool, and enters the basin. The water should rise about 24 in. above the bottom, about 8 in. being left between the bottom and the end of the arms, in order that the dirt may issue freely through the holes in the bottom, the wool floating in the upper part during the beating. A cap is fitted on the framing to retain in the basin any wool which might otherwise be thrown out during the working of the arms. The machine is placed in a wooden basin or reservoir, deep enough to hold about 16 in. of water and receive the dirt from the wool. This reservoir may be replaced by one in masonry. In using this machine in a watercourse the reservoir would be surpressed, and two would be adapted side by side at the bottom of the copper basin. Lastly, a pipe is fitted to this crushing machine to permit any excess of water to escape, and serve at the same time for exit of the dirt as it is deposited. *Patent abandoned.*

1917. R. A. **Brooman.** *Improvements in the construction of blast furnaces.* (A communication.) Dated July 1, 1862.

The object of this invention is to enable the lower portions of blast furnaces, and those subjected to most wear, to be removed when necessary, and replaced by similar and duplicate portions, without materially interfering with or stopping the working of such furnaces. The invention consists, 1, In the construction of blast furnaces in two parts, one part being fixed and the other moveable, as hereafter described. 2, In the employment of a trough extending round the furnace in the thickness of the wall thereof, for containing water, air, or other cooling agent, as hereafter described, in order to prevent any adhesion of the parts at the points of junction. 3, In the employment of sight holes in the lower part of the bushes and side of the crucible, whereby the state of wear of those parts may be viewed, in order to ascertain when they should be removed. The upper or fixed portion of the furnace, including the upper portion of the bushes and upwards, is built of fire brick, and rests on metal blocks extending round the furnace; the upper flange of a double flanged plate rests on the top metal blocks just named, while the lower flange supports the metal, water, or air trough. This trough forms the lowest part of the fixed portion of the furnace. Apertures are formed through the lining, and the double flanged plate before mentioned and walls of the furnace for the reception of bars of metal, which may be hollow or solid, and which are inserted through these apertures, and meet in the centre, for supporting the contents of the upper part of the furnace when the lower portion is removed. The lower and moveable portion of the furnace, from the lower part of the bushes downwards, is encased in a metal jacket, and is supported at bottom on a short metal platform with flanged edges, and this platform is supported upon axles carrying flanged wheels, which are made to run on rails below when a shift is required. Sight holes, before named, and tuyers are formed in the thickness of the walls of the lower portion of the furnace. A conical space is left all round between the water trough and the top of the moveable portion, and this is filled with refractory sand. To remove the moveable from the fixed portion of the furnace, when wear in the lower parts renders this desirable, bars are inserted through the apertures, before named, for the purpose of supporting the contents of the upper part of the furnace; and prior to their insertion the temperature should be reduced at the point of insertion, which may be effected by the injection of cold air or water. This done, all the furnace below the trough is lowered until the wheels rests on the rails; it is then run away, and a second and similar portion of a furnace, ready charged and heated, is rolled in to take its place; it is raised into the place of that removed, the bars are withdrawn, and the working proceeds as before. *Patent completed.*

1918. C. **Lungley.** *Improvements in constructing, building, and working floating docks and other floating bodies, and in pumping apparatus to be employed therein.* Dated July 1, 1862.

This invention will be described and illustrated in a future Number of this journal. *Patent completed.*

1919. G. H. **Birkbeck.** *Improvements in processes for the utilization of certain refuse products resulting from the manufacture of iron, such processes being applicable to the treatment of other metallic or mineral substances.* (A communication). Dated July 1, 1862.

The refuse material which it is proposed to treat and utilize according to this invention, consist of the slag and "scoriœ" obtained from the puddling or other furnaces employed for manufacturing or refining iron, and in reheating (or melting), the heads, "gyts" and waste top pieces of cylinders or other castings, the waste metal worked from "squeezers," "shinglers," pressed, or from other operations employed in the manufacture of iron, together with the treatment of waste or refuse metal generally, wherein a large proportion of valuable iron is contained, varying in most cases from 40 to 70 per cent. This richness is increased by a great quantity of metallic globules contained in the mass of these materials. The means employed according to this invention, for utilizing the whole of these materials, are exceedingly simple and inexpensive, and consist of two operations: first, In pulverizing them by means of edge runners, stampers, or other mechanical means; and, secondly, In their carburation previous to their introduction into the blast furnaces; this process being effected without additional cost of fuel. *Patent completed.*

1920. J. and G. **Greenhalgh.** *An improved diminishing valve, and also a water or steam escape apparatus to give alarm in case of fire, and to assist in quenching the same.* Dated July 1, 1862.

This invention consists, 1, In an improved diminishing valve. The patentees form the valve with the pistons, and make in one a number of inclined slots. The valve works in a pipe or cylinder forming part of the valve box or chamber connected to the steam or water pipe, and on the top of the valve there is a spring which is adjusted to any desired pressure by a screw. When the steam or water is admitted, it presses against the piston on which the spring acts, and brings the other piston nearer the passage, so that the inclined slots shall give more or less opening, according to the pressure. Or they make the valve with three pistons, and make inclined slots in two of them, and weigh the valve by a lever and weight. This invention consists, 2, In an improved self-acting fire alarm, and water or steam escape. The patentees suspend a weight by a band of gutta percha, cord, or other material, that can be consumed by fire, over a lever and catch in connection with a valve on a pipe containing water or steam, so that, when the band is consumed, the weight shall fall on the lever, and allow the valve to be opened for the steam or water to escape, and thus quench the fire. *Patent completed.*

1921. T. **Fellowes** and H. **Hemfrey.** *Improvements in apparatus for elevating straw and other agricultural produce.* Dated July 1, 1862.

For the purposes of this invention an endless rope, chain, or band, is employed, to which several apparatus are applied, each of which collects a quantity of straw or other agricultural produce; and having collected such quantity, the parts of the apparatus are arranged to close towards each other, and to retain the collected quantity securely till the apparatus has been raised by the movement of the endless rope, chain, or band, to the highest position, where the parts of the apparatus are caused to relax their hold of the straw or other produce, and allow it to drop on to a stack or other surface whereon it is desired to deposit such straw or other produce. The endless rope, chain, or band, is carried by two pulleys or wheels kept at the desired distance apart, in order that one pulley may be in the position where the straw is supplied from a thrashing machine, or otherwise, and the other pulley held in a position above the stack or other surface on to which the straw or other produce is to be deposited when it has been raised. *Patent abandoned.*

1922. J. M. **Dunlop.** *Improvements in cotton gins.* Dated July 1, 1862.

The cotton gin, known as Macarthy's, consists of a roller with leather lapped round it in a spiral direction, and having a metal blade or doctor pressed up against it. With these are combined a feed table, on which the seed cotton lies, and from which it is taken by the workman who applies it to the roller, so that it may become nipped between it and the doctor. There is also a vibrating blade or beater plate, the edge of which passes rapidly to and fro in front of, and close up to, the lines of nip between the roller and the doctor, and which serves to knock the seed out of the seed cotton there nipped and held; the seed falls off, and the fibre passes round with the roller, and is removed at the back. The patentee has found that cotton gins of this description are improved by the addition of another roller and doctor; the second roller is placed parallel to the first, and close to it. The rollers revolve in opposite directions, and away from each other at the front. They have a single beater plate between them, one edge of which serves to beat for one roller and the other for the other. The length of the beater arms is made adjustable, as is usual, to set it up to one of the rollers, and the bearings of the additional roller are so arranged that they can be set up by screws, or otherwise, to adjust it to the beater blade; after this has been set to, the first roller, or the bearings of each roller, may be made adjustable, and then no adjustment is requisite in the arms which carry the beater plate. In place of making the rollers revolve away from each other at the front, they may be made to revolve towards each other, and have one doctor between the two. In this case two beater plates are employed, but they are carried and actuated by the same arms and parts. *Patent completed.*

1923. W. E. **Newton.** *Improved machinery for washing wool.* (A communication). Dated July 1, 1862.

In carrying out this invention, an oval wash-tub is used, and is provided with a longitudinal central partition which does not reach either end of the tub. A rotary paddle is also adapted to a horizontal shaft for stirring the wool and cleaning it by dashing it about in the water. An endless apron made of wooden slots secured to bands is mounted between two segmental frames, having teeth on their edges, which gear into pinions so that the frame and endless cloth may be raised and lowered as desired. When the wool has been washed sufficiently, the endless cloth is lowered and raises the wool out of the water, and delivers it to a pair of squeezing rollers, which squeeze out the water and then deposits the wool on an endless travelling apron, whereby it is conveyed out of the machine. *Patent completed.*

1924. E. De Lebastida. *A new method of manufacturing india-rubber articles by the combinations of pressure and vulcanization.* (A communication.) Dated July 2, 1862.

In carrying out this invention the patentee constructs press plates of cast or wrought iron of considerable length, say from 10 to 30 ft., and from 1 to 100 ft. wide, and these plates are heated by steam, having chambers attached or partly formed by them, into which steam can be admitted. He so arranges these plates that the bottom is by preference a fixture or immovable table, and the top is made to rise and fall by means of screw, hydrostatic pressure, or any other convenient means. When he is about to make long pipes or tubes, he forms them in the usual way from solid sulphur composed of india-rubber, or of such compound of india-rubber and strong woven fabric, and he prepares a mould to receive it, and then places the mould with the tube in it upon the press table, and brings the top down with pressure enough to perfectly close the mould; in this way such length of the pipe or tube is subjected to heat, and vulcanized by means of the steam-heated press plates; and so soon as this is accomplished (which will be known by an experienced workman, after a trial or two). He then raises the top plate and opens the mould, and introduces another part of the same tube or pipe into the mould, and proceeds as before to vulcanize it, and thus he goes on piece by piece of one length of pipe. And, in order to make greater lengths than have hitherto been made, he leaves a piece of the ends of the tube or pipe out of the mould and unvulcanized, to one end of which he attaches or joins in a form and substantial manner the unvulcanized end of another piece which has been all vulcanized but the ends, and he then puts the joined, unvulcanized part, into a short mould suitable for the purpose, and submits the same to vulcanization. It will thus be seen that, by first vulcanizing all but a short piece of the two ends of, say 100 pieces of pipe or tubing, each 100 ft. long, and then uniting the ends of each as before described and vulcanizing them, he makes one perfectly vulcanized and unbroken tube of 10,000 ft. long by the combination of the large press and the small press, together with the process of joining in the manufacture of pipes and tubes. *Patent completed.*

1925. W. Porter. *Improvements in the manufacture of targets.* Dated July 2, 1862.

This invention consists in the construction of targets with two faces for gun, pistol, or rifle practice, whereby the "bull's eye" in one face of the target is set or brought into position when the other is struck, the improvements being particularly applicable to miniature targets, suitable for indoor snap cap practice and aiming drill. The miniature target, when placed at certain distances, represents in appearance the full size or regulation target, as it appears in reality at long distances from the person aiming thereat. *Patent abandoned.*

1926. J. James. *An improved mode of welding railway crossings.* Dated July 2, 1862.

The object of this invention is to make a more sound and secure welding of this important portion of a railway at a less cost than the mode in present practice. The invention consists in heating the rails or plates in a reverbatory or other furnace or fire, in placing them in moulds according to the sections of the rails or plates, which moulds are used as ordinary top and button tools, and in welding them under a Nasmyth's steam hammer, or other like suitable hammer, or otherwise welding them in a press or squeezer. *Patent completed.*

1927. J. Ellerbeck. *Improvements in looms for weaving.* Dated July 2, 1862.

In order to vary the force of the blow given to the picking motion, according to the width of the loom or other purpose required, the inventor employs the under picking stick, and places upon its cap a wide picking cam with a slot in it, and connects the cam to one arm of an L lever, working on a stand fixed to the loom side, having a nib on its other arm acted upon by a tappet on the tappet shaft. The slot in the cam on the picking stick cap is for the purpose of changing the position of its connection with the arm of the L lever, bringing the position nearer or farther from the centre of motion, thereby lessenning or increasing its traverse, and, consequently, lessening or increasing the force of the pick. *Patent abandoned.*

1928. B. Johnson. *Improvements in rope wheels for mines, collieries, and other similar purposes.* Dated July 2, 1862,

The object of thisinvention is to afford the means of a ready adjustment of the length of the winding rope between the rope wheel and the cage or article to which it is attached. On the shaft of the rope wheel the inventor fixes a boss in two parts, and having a flange on the outside, so as to form between them a circular groove, into which is fitted the rope wheel in such manner that it may be turned upon the boss when required, and afterwards bolted to the side flanges by bolts. In the side flanges he drills, in a circle of a given diameter, a number of holes, and in the solid part of the rope wheel around the boss he drills. in a circle of the same diameter, one, two, three, or more holes; more than there are in the side flanges, so that the bolts employed for holding the wheel and boss together can be passed into different holes, and thereby obtain a very delicate adjustment of the length of the rope. Thus, when there is one hole more in the rope wheel than in the flanges, if two bolts have been passed through two sets of holes opposite each other, and then withdrawn, so that the rope wheel can be turned to allow them to be passed through the next set of holes, the winding rope will be shortened a distance proportionate to a fractional part only of the circumferential distance between the holes, and if the rope wheel be turned to the next following set of holes, another fractional part will be added, and so on, the different numbers of the holes producing an effect similar to the use of the verner in philosophical instruments. When the boss consists of one part only, the rope wheel is to be formed of two parts, in order to place it between the flanges; or the plan may be varied by having the wheel of one piece and one of the flanges moveable. *Patent abandoned.*

1929. T. L. Atkinson. *Improvements in the construction of stew pans and other such like cooking utensils.* Dated July 2, 1862.

This invention consists in forming the boiler or stew-pan with an inner lining, within which are placed the articles to be cooked. The space between the inner lining and the outer holds the water which is introduced through the hollow handle, this being closed by a plug; the steam from the water enters into the interior through one or more holes formed in the upper part of the inner lining by means of the steam thus introduced. *Patent completed.*

1930. G. H. Hulskamp. *Improvements in violins and other similar stringed instruments, and in guitars.* Dated Jully 2, 862.

This invention is not described apart from the drawings. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Nov. 21, 1862.

3133. C. Wagner, Liverpool. Improvements in strengthening, securing, and rendering more durable the soles or bottoms of boots, shoes, and other coverings for the feet. (A communication.)

Dated Nov. 26, 1862.

3174. J. R. Danks, B. P. Walker, and R. P. Walker, Wolverhampton, manufacturers. Improvements in machinery or apparatus for making boot and shoe heel and toe tips, clog irons, and other similar articles.

Dated Nov. 27, 1862.

3181. D. and D. Auld, Glasgow, engineers. Improvements in working furnaces and steam boilers, and in apparatus connected therewith.

Dated Dec. 8, 1862.

3292. E. T. Hughes, 123, Chancery-lane. Improvements in galvanic apparatus. (A communication.)

Dated Dec. 16, 1862.

3358. J. J. Lemon, 10, New Compton-street, Soho, fancy wood and ivory turner. Improvements in book trays or holders.

Dated Dec. 19, 1862.

3399. D. Davidson, Woodcroft, Morningside, near Edinburgh. Improvements in the construction of telescopes, and in the method of arranging and fixing the same in combination with firearms for the purpose of adjusting the aim thereof.

3401. J. Dalton, Brooklyn, United States. Improvements in knitting machinery.

Dated Dec. 26, 1862.

3455. J. Swainson, Newton Stewart, Wigton, wood agent. Improvements in the manufacture of pill boxes and similar boxes from solid wood, and in machinery to be employed in the said manufacture.

Dated Dec. 29, 1862.

3464. A. W. Sleigh, knight, 16, Rue de Chateaubriand, Champs Elysees, Paris. An improved method of rendering or making ships and vessels and floating and shore batteries, or ambulent or stationary defences, impenetrable to shot and shell, and to other missiles and projectiles and war rams.

Dated Dec. 31, 1862.

3481. B. Bottomley, Rochdale, cotton spinner. Improvements in machinery for twisting and doubling yarns or threads of cotton and other fibrous materials.

3485. J. W. P. Field, 233, High Holborn, gun maker. Improvements in breech-loading firearms.

3487. J. M. Napier, York-road, Lambeth. Improvements in heating apparatus.

Dated Jan. 1, 1863.

1. R. H. Collyer, Beta House, 8, Alpha-road, Regent's-park. Improvements in the method of, and apparatus for, preparing materials for the manufacture of paper and similar purposes, part of the invention being also applicable to other operations in which materials are subjected to the action of hot agents.

3. G. Allcroft, New Church-row, Camberwell. Improvements in pressure gauges and vacuum gauges.

5. J. T. Smith, Lee, Kent, gentleman. Improvements in obtaining motive power from steam and the products of combustion.

7. J. J. Southgate, Kensington, builder. Improved arrangements for portable fire escapes.

9. W. Soutter, coppersmith, Birmingham. Certain apparatus for raising and planishing metals.

11. J. E. Baker, Cheapside, and J. Landon, Crosskey-square, Little Britain, boot makers. Improvements in the construction of boots, shoes, and other coverings for the feet.

Dated Jan. 2, 1863.

13. F. C. Bakewell, 6, Haverstock-terrace, Hampstead. Improvements in apparatus for burning oils and other inflammable fluids as fuel. (A communication.)

15. H. Lyon, 31, Sydney-street, Commercial-road, cigar manufacturer. Improvements in the finish and mode of packing cigars, and in apparatus used for these purposes.

17. E. T. Hughes, 123, Chancery-lane. Improvements in producing designs upon velvets, cloth, furniture hangings, and similar materials. (A communication.)

19. H. J. Sergeant, Manchester, silk finisher. Certain improvements in the method of dressing and finishing silk fabrics, and fabrics composed of silk, cotton, and wool.

Dated Jan. 3, 1863.

23. H. Jones, Manchester, engineer. Certain improvements in steam engines.

25. W. Phillippi, iron works, Stromberg, Prussia. Improvements in the manufacture of bearings and axles boxes for machinery, carriages, and railway rolling stock.

27. W. Astrop, Jubilee-street, Stepney, stationer. Improvements in the manufacture of paper.

28. C. B. Clough, Lewyn Offa, Mold, Flint, esquire. Improvements in apparatus for curing smoky chimneys.

29. W. T. Smallware, manufacturer, Fazeley, Stafford, and C. B. Weaver, Fazeley. Certain improvements in treating or covering strip steel, or other sitnable material, for the making of crinoline skirts and other similar purposes for which the same may be applicable, and which same treatment or covering may be used for trimming or strengthening certain parts of ladies' dresses.

Dated Jan. 5, 1863.

31. E. B. Keeling, Gray's-inn, architect. An improvement in lighting halls, theatres, and other buildings.

33. J. A. Cooper, Trowbridge, gentleman. The application of a fibre obtained from a certain plant as a substitute or to be used with silk, cotton, flax, and such like materials, which fibre has not hitherto been applied to any of those purposes, and for certain methods of preparing the same for such purposes.

35. H. Blacktin, Bradford, York, saw maker and ironmonger. Improvements in means or apparatus for saving or preserving money, papers, or other valuable property at sea in case of shipwreck. (A communication.)

37. H. Bessemer, Queen-street-place. Improvements in the construction and mode of working apparatus to be employed in pressing, moulding, shaping, embossing, crushing, shearing, and cutting metallic and other substances.

39. D. Nevin and W. Coppin, Londonderry. Improvements in machinery for clearing and separating the woody parts from the fibrous portion of flax, hemp, or other like material.

Dated Jan. 6, 1863.

40. J. A. Munn and J. D. Cobb, 8, Gresham-street, merchants. Improvements in automatic walking dolls and other figures. (A communication.)

41. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in magneto-electric telegraphs. (A communication.)

44. J. Leigh, Manchester, gentleman. Improvements in the treatment of gas produced by the distillation of coal, cannel, bituminous shale, boghead, mineral oils, petroleum, or other combustible substances, and for the obtaining of certain products therefrom.

45. T. and T. Vicars, and T. Ashmore, Steel-street, Liverpool, engineers. Improvements in machinery for manufacturing bread, biscuits, and other like articles.

46. J. A. Knight, 4, Symond's-inn, Chancery-lane, American law agent. Improvements in printing presses. (A communication.)

47. M. Hodgart, Paisley, engineer. Improvements in presses for pressing cotton and other substances. (A communication.)

49. J. G. Dahlke, Battersea. Improvements in machinery for cutting clay in the manufacture of bricks, tiles, and similar articles. (A communication.)

50. G. Turner, shoe manufacturer, Campbell-square, Northampton. A new method of making leather from waste pieces of common leather.

51. J. Whitworth and W. W. Hulse, Manchester, engineers. Improvements in ordnance.

Dated Jan. 7, 1863.

53. J. Neale, 11, King's-road, Ballspond, gentleman. Improvements in the manufacture of capsules. (A communication.)

54. T. F. Cashin, Sheffield, civil engineer. Improvements in covering wire, crinoline steel, or hoops or skirts.

55. W. Crabtree, Newton Green, near Todmorden, manufacturer, and J. Crowther, weaver. An improved mode of perching and dressing textile fabrics during the process of weaving.

56. W. S. Bruce, Great St. Helen's. Improvements in lucifer matches, fusees, and other similar lights, and in the boxes or holders for containing the same. (A cammunication.)

59. G. C. Grimes, 8, Wandle-terrace, South-street, Wandsworth. Improvements in means or apparatus for treating splints used in the manufacture of matches and other lights.

63. G. T. Bousfield, Loughborough-park, Brixton. Improvements in skate fasteners. (A communication.)

64. H. Harben, Oxford-villa, Haverstock-hill, gentleman. Improvements in the manufacture of fibrous material for cleansing machinery and other purposes.

65. J. H. Johnson, 47, Lincoln's Inn-fields, gentleman. Improvements in the permanent way of railways. (A communication.)

Dated Jan. 8, 1863.

70. R. T. Monteith, St. Malo, France, British Vice-Consul, and R. Monteith, 64, Crystal-terrace, Greenheys, Manchester, gentleman. Improvements in the manufacture of dyes from aniline and its analogues. (A communication.)

Dated Jan. 9, 1863.

74. R. Thomas, 70, Berners-street, Oxford-street. Improvements in apparatus for rendering hair wavy.

78. D. B. Parsons, 77, Upper Thames-street. Improvements in reaping and mowing machines. (Partly a communication.)

80. D. Collinge, Oldham, cotton spinner and manufacturer. Improvements in machinery or apparatus for cleaning and preparing cotton or other fibrous materials to be spun.

82. G. B. Price, Bedford, engineer. Improvements in sights for firearms.

84. M. Henry, 84, Fleet-street. Improvements in furnaces. (A communication.)

Dated Jan. 10, 1863.

86. W. Grove, Tenbury. Improvements in apparatus for sawing wood and other substances.

88. M. Vogl, Sambrook-court, Basinghall-street, merchant. An improved fastening for bags and other articles.

Dated Jan. 12, 1863.

92. D. Dawson, Milnsbridge Chemical Works, Huddersfield. Improvements in manufacturing "magenta" colour or dye.

94. E, Stevens, 139, Cheapside. Improvements in ovens, hot plates, and cooking apparatus.

96. W. Clark, 53, Chancery-lane, engineer. Improvements in carding engines. (A communication.)

Dated Jan. 13, 1863.

100. T. G. Lewis, Cumberland-place, Newington-butts, perambulator maker. Improvements in apparatus applied to perambulators, invalid chairs, and other carriages.

104. W. Platts, Manchester, merchant, and J. Bailey, cotton dealer. Certain improvements in telegraphic cables.

106. C. H. Townsend and J. Young, Bristol, engineers. Improved compositions for preventing incrustation and corrosion in steam boilers and condensers.

110. C. E. Amos, Grove, Southwark, engineer. Improvements in machinery for the manufacture of paper.

112. T. Butler, manager, Nottingham. Improvements in the manufacture of lace in twist lace machines.

114. H. Bessemer, Queen-street-place, Cannon-street. Improvements in the manufacture and treatment of malleable iron and steel, and in furnaces, machinery, and apparatus employed in such manufacture.

Dated Jan. 14, 1863.

118. J. S. Butler, St. Alban's-terrace, Nottingham, lace manufacturer. Improvements in the manufacture of bobbin net made on bobbin net or twist lace machines.

120. G. A. Biddell, Ipswich, mechanical engineer. Improvements in machines for pulping turnips and other vegetable substances.

122. J. Lawson, Hope Foundry, Leeds. Improvements in apparatus for holding castings and other pieces whilst being planed or shaped.

124. G. Holt, 5, Canterbury-place, Lambeth-road. Improvements in apparatus for sweeping or cleaning chimneys, and also in apparatus for preventing chimneys from smoking.

Dated Jan. 15, 1863.

128. W. Hulse and C. L. Haines, Birmingham, metallic bedstead manufacterer. Improvements in machinery for the manufacture of taper metallic tubes.

130. T. C. Barraclough, Manchester, engineer. Improvements in apparatus for cutting metallic tubes or pipes, or tubes or pipes composed of other indurate substances. (A communication.)

136. C. Murrell, Pinfold-street, Aylsham, Norfolk, joiner. Improvements in breech-loading firearms.

140. A. Prince, 4, Trafalgar-square, Charing-cross. Improvements in sewing machines.

INVENTIONS PROTECTED FOR SIX MONTHS BY THE DEPOSIT OF A COMPLETE SPECIFICATION.

Dated Jan. 14, 1863.

119. G. T. Bousfield, Loughborough-park, Brixton. Improvements in machinery for rolling, grinding, and cutting files. (A communication.)

Dated Jan. 17, 1863.

155. G. T. Bousfield, Loughborough-park, Brixton. Improvements in hot-air engines. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, Tuesday 27.

2534. H. M. Radloff. Filtering oils.

2540. G. L. Lee. Metallic shutters, doors, and windows.

2547. L. Leigh. Stretching and glossing fibrous materials.

2549. R. Cranston. Washing machine.

2553. J. Douglas. Fire ranges.

2555. J. H. Johnson. Gas burners. (A communication.)

2560. W. H. Browne and H. Armstrong. Gas meters.

2570. D. C. Bridge and J. Dyson. Warming buildings and similar purposes.

2574. J. Imray. Telegraphing. (A communication.)

2575. R. R. Jackson and J. Coupe. Looms.

2577. G. Maw. Tesseræ and other mosaic inlays.

2583. J. Wilson. Boilers.

2584. A. Prince. Furnaces. (A communication.)

2590. M. Vogl. Fastening articles of wearing apparel.

2605. W. Maddick. Treating and preparing madder.

2607. R. R. Jackson and Æ. I. Jackson. Treatment of flax and other fibrous materials.

2608. R. R. Jackson and Æ. I. Jackson. Cutting fibrous materials.

2613. T. Kennedy. Taps or valves.

2614. F. Tolhausen. Steam cultivator. (A communication.)

2615. J. Raywood. Gas apparatus.

2616. J. R. Breach and E. B. P. Smith. Reducing or equalizing the length of animal or vegetable fibres.

2617. J. Eardley. Pitch or tuning pipes.

2626. E. Dixon. The manufacture of welded iron tubes.

2634. M. Henry. Improved applications of petroleum and its products. (A communication.)

2661. W. C. Cambridge. Washing clothes.

2672. W. Clark. Atmospheric toy pistols and guns. (A communication.)

2673. W. Clark. Candlestick. (A communication.)

2720. M. A. F. Mennons. Self-inking hand stamps. (A communication.)

2729. J. B. Palser. Manufacturing of paper pulp.

2735. J. Lowe and J. Harris. Propeller.

2824. J. B. Payne. Fibrous substances.

3101. R. Beck. Reading glasses and magnifyers.

3117. G. W. Oldham. Preparing fibrous substances.

3123. J. W. Hjerpe, W. Holmgren, and A. V. Sundstedt. Composition or preparation of materials applicable for igniting matches.

3388. J. and A. Brierley. Carding engines.

3428. J. Whitley and J. W. Burton. Permanent way.

3476. W. Mould. Plaiting or folding and measuring fabrics.

19. H. J. Sergeant. Dressing and finishing silk fabrics.

41. W. E. Newton. Magneto-electric telegraph. (A communication.)

67. L. Hull. Treatment of ground caoutchouc.

130. T. C. Barraclough. Cutting metallic tubes or pipes. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Jan. 21, 1863.

2083. R. Grogan.
2099. R. Bell.
2100. J. Leetch and B. Mathew.
2103. W. Clissold.
2106. J. G. Clarke.
2107. W. H. Perkin.
2110. H. A. Jowett.
2111. J. and H. Redgate.
2112. J. Anderson.
2113. P. Robertson.
2114. W. Clark.
2124. J. H. Selwyn.
2127. J. Walton and J. Moore.
2128. H. Bollinger.
2135. T. Cook.
2136. A. Noble.
2160. B. Bailey.
2223. N. J. Amies.
2239. W. E. Newton.
2243. N. J. Amies.
2278. J. H. Johnson.
2286. G. White, F. Buckland, and C. Rees.
2349. D. Moore.
2351. D. Moore.
2358. M. Henry.
2382. A. V. Newton.
2756. C. Thomas.
2928. G. Mayall and J. Hollingworth.
3160. E. Wadsworth.
3198. W. E. Gedge.

Sealed Jan. 23, 1863.

LONDON, FRIDAY, FEBRUARY 6, 1863.

THE ADMIRALTY POLICY IN NAVAL CONSTRUCTION.

Together with the announcement of the appointment of a new Chief Constructor of the Navy, and of further prospective changes in the constitution of the Comptroller's Department at Whitehall, we have the gratifying news that there will be a very considerable reduction in the Naval vote for next year.

It is apparently the intention of the Admiralty to enter honestly upon the path of reform, and we take these changes as the earnest of a better state of things.

It is, we believe, to Admiral Robinson, the Comptroller of the Navy, that very much of the credit of this is due. As a member of the Royal Commission for enquiring into the control and management of Her Majesty's Dockyards, he became thoroughly acquainted with the defective organization of the Department of the Comptroller, by which it failed to assert its independence of the Board of Admiralty in scientific matters on the one hand, and to exercise proper control over the practical operations of the dockyards, on the other.

When, upon the retirement of Sir Baldwin Walker, Admiral Robinson was appointed Comptroller of the Navy, he had the good fortune to find in the Duke of Somerset a man fully alive to the importance of the interests entrusted to him, and prepared to take any measures which his subordinate considered likely to result in the good of the service.

The most important step yet taken in this respect is that of the appointment of Mr. Reed, and we shall await with considerable anxiety the alterations which the Comptroller and his new professional adviser will make at Whitehall and in the Dockyards. In the meantime we should like to point out what has always appeared to us to be a vital error in the policy of successive administrations in naval construction. It has been the passionate desire of the English people, and the professed aim of its statesmen and official servants, to make the British Navy the most powerful in the world. We have believed it necessary to our existence that this should be so, and have never grudged any amount of money necessary for accomplishing it.

One would suppose that in order to maintain such a position it would be desirable to introduce the most efficient machinery of war which the progress of knowledge rendered available. We should have taken it as certain that the English people would never be content to use, generation after generation, the same antiquated and cumbrous machinery, allowing the courage of the seamen, and the mere number of the ships and engines of war to atone for its mechanical deficiencies.

Yet this has really been the case. No one can dispute the fact, that it has been to the courage and conduct of her seamen, and the spirit and skill of their leaders, that England has owed her naval supremacy. It has not been, notwithstanding her mechanical advantages, to superiority in ships, artillery, or any of the machinery of war. No pains have been spared, we admit, to improve the appearance, and increase the accommodation of our ships of war, so that an English line-of-battle ship has become almost perfect both with regard to outward form, and internal arrangement. But no changes whatever, of greater moment, have been *initiated* in the English Navy.

The argument of our administrators has been, "Give to our seamen as good a ship as their enemy, and there need be no fear of the issue. Any attempt on our part to improve the means of attack or defence, will certainly be followed by our adversaries, and after all the expense has been incurred, the odds will be the same as before."

But there is a fallacy here, which it behoves us, as pioneers and expounders of mechanical science, to bring prominently under the notice both of the gentlemen who now have the direction of these matters, and of the public by whom their actions will be judged.

A familiar illustration of the argument just recited is, that England is in the position of a manufacturer who has a large capital invested in his business, and occupies the foremost position in the trade. Any considerable changes in the material or mode of manufacture, renders old stock useless, or at least, greatly reduces its value. As this man has a larger stock in trade than his neighbours, he will suffer most by these changes, and it is, therefore, contrary to his interests to introduce them.

Now, this statement of the case would be quite true if the manufacturer in question had the power of preventing his rivals from making changes and improvements. But, if he have not this power, the irresistible progress of knowledge will give to a rival the *éclat* and profit of the new and improved goods, and he has to suffer a loss of position as well as the depreciation in the value of his stock.

If, on the contrary, he takes care to buy up useful patents, and to encourage invention, he will retain his *prestige*; and being constantly impressed with the necessity of avoiding the accumulation of inferior stock, he will not be likely to suffer by the changes which are in his own hands.

Thus, dropping the illustration, while we admit that the English sailor needs no better ships or better guns than his enemy—while we admit also that any improvements in these respects will be speedily followed by other nations, leaving the odds the same as before—we contend that it is, nevertheless, bad policy for a nation like England to be content to allow all important changes to originate with her rivals, and to receive from Paris or New York the latest novelties in marine architecture. The actual consequences of the adoption of this policy have been a succession of most demoralizing and costly panics, involving a great waste in the hasty construction of the ships supposed to be required, and in providing various kinds of unnecessary coast defences. Take, for example, the change from sails to steam. England is the cradle of the steam-engine; and its marvellous marine adjunct, the screw propeller, is an English creation. The powers of both engine and propeller were known and acknowledged by the Admiralty, certainly as early as 1845. The men and the material were then ready to produce a screw line-of-battle ship, which might have been built, had it not been for the credit given to the false principle we are attacking. Had this been done, there would have been some sensation at Paris and St. Petersburg, and similar ships would have been commenced in all probability by the great maritime powers. But none of these powers had any position to lose by this advance of England, and they might have been expected to make their changes leisurely, and as the finances of the State would admit.

England, on her part, need have made no undue haste to increase the number of these new creations. She would continue to employ her old ships, they being at least as good as those of her neighbours; but she would not have overstocked herself with them, nor would she build any more after their model. Every new ship required to replace an old one would be of the improved kind. It is not too much to say that the production by England of one such ship would have ensured the maintenance of her *prestige* for years, while the expenses of conversion and re-construction would have been avoided. But this was not done; and in 1850 France built the ship, which England should have built at least five years before. And although a similar ship was at once commenced in hot haste in England, the old machinery rolled on its accustomed course, so that it was not until 1859 that the House of Commons was asked to provide for the general introduction of steam into the navy.* But by this time the French Government had made another start ahead, and at the very moment when the House of Commons was voting extraordinary supplies for converting sailing line-of-battle ships into steam ships of the line, the two ships were quietly building at Toulon, which have brought about another revolution, and compelled us again to stop and re-construct.

It is true that, before the iron-cased "Gloire" and "Normandie" were launched, England had commenced her iron-cased ships; but she has continued to build and convert her uncased vessels for three years, and by extraordinary exertions has, in the end, succeeded in obtaining that screw steam fleet which was so ardently desired by our administrators in 1859. Having obtained it, we are informed by one authority that the man who goes into action in such ships is a fool, and the man who sends him there a villain.† And another‡ coolly informs us that we have no fleet except two ships—the "Warrior" and the "Black Prince." These are the plain consequences of being content with ships as good as those of our neighbours. Had we built the "Warrior" five years before, as we might have done, how different would have been our position. And the argument remains sound, notwithstanding that the assertions to which we have referred are so exaggerated as to be mere figures of speech.

To what precise extent the existence of the French iron-cased ships affects the value of the English unprotected fleet, is a very curious question.

Great damage is unquestionably due to England by the mere fact of their existence; and should there be a war between France and England, the credit of England would demand that in no part of her dominions should her unprotected ships be exposed alone to their attack.

The conclusion to which this leads is, that if England is to maintain her *prestige* as a naval power, and avoid costly and undignified panics, she must not be content with having more ships and better sailors than any of the other powers, but she must also be foremost in the creation of the machinery of war. She must not discourage thoughtful, practical men, who seek to improve our naval architecture and seamanship—she must no longer grudge the money spent in well-directed experiments; but she must consider that money well spent which saves her from such errors as those we have recorded.

---

* In her Majesty's speech, at the opening of the Parliament of 1859, she said:—"The universal introduction of steam power into naval warfare will render necessary a temporary increase of expenditure in providing for the reconstruction of the British navy."

† Capt. Sir Jno. D. Hay. ‡ Mr. J. Scott Russell.

JAMES WATT AND PATENT LAW.

THE life of "the greatest inventor of all ages and nations" offers deep and instructive lessons on patent law; lessons unrivalled for vivid intensity and practical suggestiveness. Let it not be said that we look too far back for our instance, for mankind is still only on the threshold of the practical applications of science, and the appearance of another man such as Watt, might probably effect changes of almost equal magnitude to those inaugurated in his famous patent of 1769.* There is, besides, an advantage in taking for our example the history of an invention of old date. The actors being long since dead, the truth is known more completely, from the family documents having been published. The secret history of many more recent inventions would probably tell of similar experiences.

It has been asserted by the opponents of patent rights that "even if these rights were abolished, invention would not stop. Inventors are said to invent as hens lay eggs. The most valuable inventions are made by professionals striving to improve and advance the special business in which they are engaged." It has also been asserted, that many important inventions have sprung from an accidental source, and further, that if one man did not stumble upon any given combination, the next man would be more fortunate. Invention and progress are thus said to be only questions of time. This latter doctrine has found disciples in our own day, and in reference to Watt himself, Tredgold, in his work on the steam-engine (1827) asserts—"The *fortunate* (!) idea of condensing in a separate vessel, which in Watt's engine is the only essential part in saving of fuel, beyond what Smeaton had accomplished, *would, undoubtedly, in a short time, have occurred to some other person.*" No doubt very many inventions owe their origin to professionals, to fortunate accidents, and to mere time. It is, however, no less true that some of the greatest and most original discoveries have been brought forward by outsiders; by men whose mental vision had not been shortened by a lifelong concentration on the narrow horizon of a daily practice. Men engaged at a lifelong occupation have their ideas so warped to the shape of the things continually before their eyes, that it would be difficult to convince men so circumstanced as to the advantage of any new scheme, even if it could be adopted gratuitously. Besides, the interest of a manufacturer is generally directly opposed to the introduction of a new process, that may at last supersede his own machines and his existing plant. The cry of such a class is:—"Great is Diana of the Ephesians." The great philosophic poet of Germany, Goethe, says, "Every (new) idea appears as a strange guest; before being embodied a new idea can scarcely be distinguished from imagination and phantasy. We can perceive the usefulness of an idea, and yet not see how to put it to use."

As we said, the most original inventions owe their origin to outsiders. Take amongst many instances of this phenomenon, the case of James Watt, the mathematical instrument maker. In the excellent life of Watt, written by his relative, Mr. Muirhead, this gentleman quotes the following from Desaguiliers' "Course of Experimental Philosophy," written in 1763: "These discouragements stopped the progress and improvement of this engine (Captain Savery's) till Mr. Newcomen, an ironmonger, and John Cawley, a glazier, living at Dartmouth, brought it to the present form in which it is now used, and has been near these thirty years." (The first edition of Desaguilier's first volume was published in 1734; the first edition of the second volume, from the third edition of which the above passage is taken, was published in 1744.) *It thus appears that the steam-engine had to wait nearly seventy years for the magic hand of a Watt.* It is not generally known that in some of the outlying colliery districts of England, where slack coal is plentiful, and nearly worthless, some old engines of Newcomen are still extant, or, at any rate, were so within the last few years. Newcomen's engine shows very well what mere accident can do, as also what accident cannot effect. The packing of Newcomen's piston, effected in the same way as pump buckets are still packed, was discovered by accident. Its further packing, by means of a stratum of water, was probably due to chance. The use of this layer of water also led, notoriously by accident, to the method of condensation by injection. The self-acting gear was added by a boy. Smeaton now took up the steam, or rather the atmospheric engine, and improved it by properly arranging and proportioning the engine and boiler, leaving het general principle untouched. Smeaton was an excellent engineer, but he was not a very inventive man. The history of the steam-engine thus shows very well what chance can do for progress, and also what professional men, unaided by inventors, can effect in the same direction. It might be supposed that there was little or no demand at that time for steam power. The contrary, however, was the case; as many of the most valuable Cornish mines were being abandoned from the expense in fuel of the Newcomen atmospheric engine.

Another objection to patent-right has been raised because many inventions have been made simultaneously. It no doubt often happens that when a want for anything is public and well known, the same remedy may be proposed by several men. A certain question in science or art being once definitely put, no wonder that the answers coincide. The great difficulty, however, is to put the given question in a definite manner. In "*A Plain Story,*" written by Watt himself, for the information of counsel in the several lawsuits he had to go through, Watt states:—"The matter having got firm hold of his mind, and his circumstances obliging him to make exertions to regain what he had spent (in experiments) he turned the matter over in every shape, and laid it down as an axiom, *that to make a perfect steam-engine it was necessary that the cylinder should be always as hot as the steam which entered it, and that the steam should be cooled down* (afterwards) *below* 100 *deg., in order to exert its full powers.*" This axiom being once in the possession of several men, we can conceive that several would thereupon light upon the separate condenser.

Watt, who was accustomed to say—"Nature can be conquered, if we can find out her weak side," definitely put the question, and practically answered it by creating the steam-engine, to which no new principle had been added since Watt's death.

It is scarcely possible to believe that the steam-engine could have been so soon elaborated, or even brought out at all, without the existence of some patent law. Watt himself might have carried it out, if he had been provided with funds, but he never would have got men of business to aid him without the hope of some return for their pecuniary sacrifices. Watt had nearly ruined himself in experiments, before he met with a partner. In August, 1768, he thus wrote to Mr. Boulton:—"When you were so kind as to express a desire to be concerned in my fire-engine, I was sorry I could not immediately make you an offer. The case is this:—*By several unsuccessful projects and expensive experiments, I had involved myself in a considerable debt* before I had brought the theory of the steam-engine to its present state. About three years ago a gentleman, who was concerned with me, died. As I had at that time conceived a very clear idea of my present improvements, and had even made some trial of them, though not so satisfactory as has been done since, Dr. Roebuck agreed to *take my debts* upon him, and to lay out whatever more money was necessary, either for experiments or securing the invention; for which cause I made over to him *two-thirds* of the property of the invention. The debts and expenses are now about £1,200." To illustrate the necessity of an alliance of a monied partner with an inventor, which also implies the necessity of a patent law, we will quote the words of Dr. Robison:—"Watt's situation in life made it imprudent to engage in great expenses, and he was obliged to look out for an associate. Most fortunately there was in the neighbourhood such a person as he wished, Dr. Roebuck, a gentleman of very uncommon knowledge in all the branches of civil engineering, familiarly acquainted with the steam-engine, of which he employed several on his collieries, and deeply interested in this improvement. He was also well accustomed to great enterprises—of an undaunted spirit, not scared by difficulties—not a niggard of expense. *Such a man was indispensibly necessary to one of Watt's character—modest, timid, easily frightened by rubs and misgivings, and too apt to despond.*

Watt wrote, November, 1772, to Dr. Small—"I would rather face a loaded cannon than settle an account or make a bargain. In short, I find myself out of my sphere when I have anything to do with mankind; it is enough for an engineer to force Nature, and to bear the vexation of her getting the better of him. Give me a survey to make, and I think you will have credit of me; I can draw tolerably; set me to contrive a machine, and I will exert myself."

As a forcible instance of the value that is set by the multitude on an invention that is not ocularly, tangibly, and practically in full operation, we will further quote the following:—"None of his creditors (Dr. Roebuck's) value the engine at a farthing," wrote Watt to Dr. Small, July 25, 1773. It also appears that even Watt himself had but a low opinion of the pecuniary value of the invention. As everyone knows, Matthew Boulton, in 1773, took Watt into partnership,. After working together for two years, and six years of the patent of 1769 having thus expired, it became evident that in the then state of mechanical art, the remaining eight years of the patent would only suffice to make the engine practicable, without at the same time affording any return in the shape of profit.

Messrs. Boulton and Watt then determined to apply for an Act of Parliament to prolong the patent for 25 years. Watt wrote to his father, May, 1775—"The affair has been attended with great expense and anxiety, and without many friends of great interest, I should never have been able to carry it through; as many of the most powerful people in the House of Commons were opposed to it." Strange to say, the famous statesman and orator, Burke, opposed the measure.

As the importance of the invention was not yet generally recognised, the prolongation of the patent does not seem to have been opposed by those interested in using and manufacturing steam-engines. Watt wrote to Mr. T. Parker in 1797:—"One fact, however, I must inform you of is, that, prior to the Act of Parliament, we had sold no engines, though we had made some; they were merely to satisfy ourselves,—and had the act not passed the invention had fallen to the ground." Another crime of mediocrity on genius would thus have to be inscribed in the annals of humanity, and Watt's name narrowly missed being added to the long list of the "Martyrs of Science." The prolongation of the most momentous and valuable patent ever taken out, affords a very interesting and striking instance of the importance of prolonging patents. Boulton and Watt spent enormous sums on the steam-engine before getting any return. Mr. T. Webster was asked, before the Patent Law Committee of the House of Lords, in 1851:—"Are you not aware that Mr. Watt made no profit whatever by his original improvement of the steam-engine? Answer—None.

---

* 1769 was the date in which Arkwright took out his first patent. This year, as is well known, also witnessed the birth of Napoleon I., Wellington, Mehemet Ali, Castlereagh, Humboldt, Cuvier, and M. I. Brunel, and of some other great men.

"Are you aware that, if his patent had not been extended for 28 years, he would have been rather injured than benefitted by his inventions? Answer—There is no doubt of it.

"The first 14 years yielded no benefit to him? Answer—That has been the case with many patents of that class." (Watt's original patent was sealed on the 5th January, 1769, and in May, 1775, he got it extended for 25 years; it therefore expired in 1800. The patent thus lasted more than 31 years, and *not* 28 years only.)

Mr Bennett Woodcroft, the distinguished patent commissioner, was asked before the same committee:—"Do you think that there ought to be any alteration in the law with regard to the duration of patents? Answer—I think they are too short—very much too short for me. I have here a list of the first 25 patents that were granted by James the First. The term of the first grants of patents was 12 years, and all the rest were 21 years, except some two or three for 31 years.

"Would you, as a general rule, grant the same term to all patents? Answer—*The difficulty is to decide which ought to have a long and which a short patent; some pay immediately, and some it takes years to mature, and it would be well if it could be decided.*" Probably the present state of the law is best, whereby a patent may be prolonged, on its being shown that no adequate profits have been derived during the 14 years of the patent. The law costs of a prolongation are, however, too high for a poor patentee. An American patent cannot be prolonged, but the duration of a patent in that country is 17 years. It is also evident that some distinction ought to be made between patents for crinoline and patents for steam-engines.

We now come to a very painful period of Watts's life—that period, namely, during which he encountered the pirates and infringers of his inventions. Watt was, for no less than seven years, engaged in these law suits. It is marvellous how the morality and honesty of some people are bounded by the range of their five senses; how men, who would scorn to appropriate things they can see, smell, taste, or touch, do not scruple to rob tangible ideas. And yet, as John Stuart Mill has it:—"No limit can be set to the importance, in a purely productive and material point of view, of mere thought." Manufacturers of thread, of buttons, or of crinolines, may earn fortunes, but men refuse to pay for the ideas manufactured by men of genius. The pirates of Watt's patent were doubtless encouraged by the success of similar manœuvres against Hargrave, Arkwright, and Crompton, the three first inventors of spinning. Mr. Farey, the distinguished engineer and scientific writer, says—"Of the three inventors of spinning, Hargrave, Arkwright, and Crompton, to whom the nation have owed so much, the first was persecuted, and died in the greatest poverty, amidst a population who were rising to opulence by his means. Arkwright possessed a vigour of mind to command, control, and instruct workpeople far beyond the talent of a mere artist or inventor, and succeeded in realizing a princely fortune by his manufactory; but his money was not gained by virtue of his inventions, for the bulk of it was acquired after his patent was set aside, and others who invented nothing, but merely copied what he did, made immense fortunes by spinning, as well as himself. Crompton, whose combination of Hargrave and Arkwright's inventions in the mule, has more than doubled the national advantages conferred by his predecessors, was, like Hargrave, ruined in his circumstances, and languished in poverty during a long life in the very towns which had grown up from insignificance to wealthy importance by the practice of his inventions. In 1812, his case reached the knowledge of Parliament, and £5,000 reward was given him; but it came too late to have the effect of removing the established impression, that an inventor is almost certain to be ruined, even if his invention succeeds, and proves ever so valuable to others."

The formal objections against Watt's patent, act, and specification, seem to have been much stronger than those which were successfully urged against Arkwright's patents. In fact, the specification of 1769 did not put the public in possession of the invention. Nevertheless, the mere fact of attacking the patent, on the score of its being informal, showed great immorality on the part of the pirates; a technical defect in a title-deed does not give an honest right to another's land. Fortunately for Watt, England and the world, right at last prevailed, and Watt long afterwards "used to call the specifications his old *and well-tried* friends."

If Watt had been refused a prolongation of his patent, or if his patent had been upset, it is not at all improbable that we should have soon felt disastrous political effects from this cause. "It is our improved steam-engine," wrote Lord Jeffery, in 1819, "that has fought the battles of Europe, and exalted and sustained, through the late tremendous contest, the political greatness of our land. It is the same great power which now enables us to pay the interest of our debt, and to maintain the arduous struggle in which we are still engaged, with the skill and capital of countries less oppressed by taxation." Even supposing that the steam-engine had been put aside for only 20 years, we should have lost the increase of wealth that enabled England to meet the tremendous wars of the first French Republic and Empire.

The anxiety and bitterness, however, engendered in Watt's mind by these attempted piracies, were very great. Watt wrote in 1782:—"If our right cannot be supported by law or custom, it is time we knew it before we waste more of our lives improving machines for the benefit of scoundrels." Later, he wrote:—"I wish my head and mind to be in the grave; and I fear they will not rest sooner." Watt was tempted in the anguish of his mind" to "curse his inventions;"—to declare that "there is nothing more foolish than inventing;—and that nine-tenths of mankind are knaves, and a large proportion of the remaining one-tenth fools." He called London solicitors "the anthropophagi of London." No wonder; for Mr. Muirhead saw one solicitor's bill alone to the tune of nearly £6,000 for the last four years of the patent! It has often struck us, that what with railway bills for civil engineers, and patent cases for mechanical engineers, the legal profession has profited more than any other class by practical science. The legal profession is so well represented in Parliament—the fountain-head of all modern English law—that we may never see any changes placing the men of matter in a more favourable position to the men of words.

Cheap litigation is a thing that is absolutely wanted by patentees and the public. The Committee on Patent Law of the Society of Arts, in 1851, quoted the following statesmanlike remarks of Lord Langdale, then Master of the Rolls:—"I consider that to check litigation by means of expense is pernicious to the public. Litigation may be most usefully prevented by cutting off its sources; but if the causes or sources of litigation are existing, the only mode of preserving the peace of society is to allow litigation to take place, and to make it easy. It is a great object of litigation to cast off the causes or sources of litigation: that I conceive to be the object of Government. But when the sources of litigation unhappily exist, instead of allowing them to rankle and fester in the minds of parties, the best and most prudent course is to let them go before an impartial judge, who may decide the matters in difference between them; and this is litigation.

The litigation in patent cases will, however, always be more or less expensive, even if such cases be less in the hands of the legal profession. The witnesses form the great expense in these cases. At present, the best talent must be obtained in both law and science. Cheap patents would be of no use as long as patent litigation is dear. What is a patent but a vested right to bring actions for infringement? On the other hand, of course the public ought to be protected at a cheap rate against undue assumptions of patent rights.

H.

ANALYTIC UNIVERSAL TELEGRAPHY.*

Notwithstanding the vast progress which has already been made in the practice of Telegraphy, much more remains to be effected. Hitherto the world has been indebted to comparatively a few persons, and those mainly Englishmen, for the advancement of the science, but now that the attention of ingenious men of all countries is directed to it, we may calculate with certainty upon its further and rapid development. The publication of the pamphlet, the comprehensive and rather ambitious title of which is placed at the foot of this column, will no doubt induce a considerable amount of curiosity, and some discussion. We are disposed to think, too, that the little work is really a valuable contribution to the literature of Telegraphy. Any attempt indeed to simplify the process of transmitting messages through the medium of the "magic wires," and to lessen its cost, must be received with favour, and deserves consideration. The position which the author of "Analytic Universal Telegraphy," holds in the Geographical Society of France is such as to give especial weight to his propositions, whilst his own faith in their practicability and value is witnessed by the fact that he has patented them in England, Belgium, France, and the United States.

---

* Analytic Universal Telegraphy; an International Telegraphic Language, simple, accurate, and three times shorter than the system at present in use, presenting neither the difficulties nor inconveniences of other cyphers. By Count D'Escayrac de Lauture, Member of the Committee of the Geographical Society of France, &c. &c. London: John Camden Hotten, Piccadilly.

The Count is very enthusiastic in enunciating his belief that a universal telegraphic language is easily obtainable, and that the system upon which it is based can readily be adapted to all existing telegraphic apparatus. His reasons for coming to conclusions so important, and if true, so likely to become illimitably advantageous to the human race, are given in an early page of the pamphlet: "A philosophical and thorough study of language has led me to the conclusion that language everywhere, and always, passes from a synthetic to a more and more analytical form; that different nations brought into contact come, in order to understand each other, to a simplification of their grammar, which becomes the more analytical in the same ratio as those nations are more amalgamated with others, as their empire is of greater extent, their civilization more ancient, and of a higher development. It will be sufficient to cite the English language as an example of this law, which has to my apprehension been clearly established by numerous facts.

"I have then thought proper to express all the grammatical accidents of a principal idea (the tenses of the verbs for instance) by separate signals, which are the same for all words and for all languages. This algebraic notation enables me, with the aid of a very small number of signs, to give all the tenses and all the persons of all the verbs. Another combination, equally simple, enables me to form instantly an indefinite number of expressions always immediately intelligible. Moreover, it enables me to form adjectives, adverbs, &c., and finally to pass from the substantive to the verb that corresponds to it, and *vice versa*."

Here, therefore, is to be found the basis upon which the learned gentleman founds his system, and it is clear that the theory has much to recommend it to the notice of international telegraphists. Further on we are told that "nearly all dispatches are about special subjects; they are either military, commercial, medical, or relate to the money market. Each of these different subjects will (by his system) possess a particular vocabulary of four hundred and fifty, or six hundred words, if the alphabet contains thirty letters. These words will be classed in small groups, like the grammatical signs, according to the affinity, or the difference of the ideas they represent, and inscribed, like the grammatical signals, on tables divided into small squares, each of which will contain a word. Every line and every column of those tables will be designated by one of the letters of the alphabet, and every word will be translated by the two letters of its line and column."

It is impossible for us to do more than indicate generally the method by which the Count de Lauture proposes to accomplish the great task he has marked out for himself, but he has gone with extreme care into all the details of that method in the pamphlet under notice, and furnished the tables and signs by the use of which he believes universality of communication is to be attained. The only objection which he supposes can be raised to his system is that of its extreme "delicacy" and consequent liability to error. This anticipated objection is combated by the assertion that there is this difference between dispatches in cypher under the present system, and under that proposed; "that he who transmits or receives the first, transmits or receives what he does not understand, whilst he that shall receive or transmit the latter will be able, except in some cases, to understand and rectify them." "It will be impossible," says the advocate of the universal system, "for the transmitter or receiver who practices it to mistake the grammatical signals or those in common use of the first table, and those signals will compose nearly two-thirds of every dispatch. An error in the other signals, a mistake difficult to commit, will be generally self-evident, and a glance at the nearest words in the same table will be sufficient to correct it."

In fine, the author and patentee of "Analytical Universal Telegraphy" is, like almost all other authors and patentees, enthusiastic in favour of his own plans. It will be for those who are directly interested in telegraphic improvements to examine and test those plans, apart from prejudice, and with a determination to do justice to their distinguished projector.

One other point we must advert to before leaving this highly-interesting subject, and it has reference to the probability of the general introduction hereafter of automatic contrivances for the transmission of telegraphic messages. Everything seems to point in that direction. Professor Wheatstone, as is well known, invented a machine for the purpose, and no doubt others will follow in his footsteps. When that desideratum is arrived at the chances of error will be materially diminished. Dispatches will then be composed and revised at leisure by the same party who translates them, and afterwards passed to the machine which will transmit them without the probability of error, and with greater rapidity than they can at present be forwarded.

Those who wish to learn more of the new system of telegraphy must be referred to the publication which has incited the foregoing remarks, and which, we feel confident, cannot be perused without advantage. Telegraphy has enjoyed a brilliant past, and we are assured that a yet more brilliant future awaits it. We do not despair of seeing another and a durable Atlantic cable stretched across the ocean's bed, uniting us to our kindred, and vibrating with messages of peace and love. The animated discussion which followed the reading of Mr. Masey's excellent paper on the "Submarine Telegraph" at the Society of Arts last week, gave evidence of the interest which is felt by scientific men in the subject, and in truth all circumstances tend to demonstrate the fact that Telegraphy must be far more widely diffused. Should the Count D'Escayrac de Lauture succeed in realising his views, it will be possible by-and-bye for a merchant of London to converse freely with a native tea grower in the Celestial Empire without the aid of an interpreter!

INSTITUTION OF CIVIL ENGINEERS.

At the weekly meeting of the Institution of Civil Engineers, on Tuesday last—John Hawkshaw, Esq., president, in the chair—the paper read was, "On the Woods used for Sleepers on the Madras Railway," by Mr. Bryce McMaster, M. Inst. C.E.

The native wood sleepers having hitherto been found for the most part to fail—on the Madras railway between 30 and 40 per cent., requiring to be renewed annually—the author undertook an investigation with a view of ascertaining the causes of this deterioration, and whether those causes could be overcome, so as to render available the vast resources of India. Thirteen hundred sleepers, of sixteen different woods, were submitted to careful examination and scrutiny twice at an interval of twelve months. The sleepers were variously placed, both on embankments and in cuttings; in some cases they were entirely covered with ballast to a depth of 4 in., while in others they were, as much as possible, uncovered, and completely so from the rails to the ends, the ballast being only raised 2 in. in the middle of the way, and sloped off so as to carry away the water under the rails. From these observations it appeared, that only five woods—Chella, Woonjay, Eloopay, Kurrah Murdah, Palay, and Karavalum,—were sound at the end of two years, the other eleven not lasting even that time. Also, that when the sleepers were uncovered, decay was less rapid than when they were buried in the ballast. The plan of leaving the sleepers partially uncovered had many advantages; it effected a saving of the ballast, allowed the defects to be more quickly detected, and kept the sleepers drier. It had been urged that the heat of the sun would split the sleepers, and cause the keys and trenails to shrink; but from experience the author was enabled to state that, while amongst the "uncovered" sleepers there was a large proportion "beginning to split," or "useless from being split," there was, on the other hand, amongst the "covered" sleepers, a still larger proportion "beginning to rot," or "useless from being rotten." It was also noticed, that of the sleepers "beginning to rot," 19 per cent. had commenced under one or both chairs. This was due to the retention of moisture under them, and might be remedied, the author believed, by tarring the seats of the chairs. As regarded the trenails, where the sleepers were rotten, the trenails were invariably found to be in the same state; while when the heads were exposed to the sun he never found them loosened by shrinking. Another objection was, that the road would be more liable to buckle and twist, but this was not found to be the case on the 40 miles of line, thus ballasted and opened for traffic, on the division under his charge. Trenails made in India cost £2 10s. to £4 per thousand, and the woods generally used for the purpose were Vengay, Kurrah Murdah, Erool, Porasa, or satin-wood, and Trincomalee. The three woods first-named were also extensively employed for keys, which were considerably larger than usual; but teak keys seemed to be the best, and their cost did not exceed £6 per thousand. From personal observation and inquiry, the author thought the following woods would make really good sleepers, to be used plain:—Teak, Saul, Sissoo, Pedowk, Kurrah Murdah, Aucha, Vengay, Chella Woonjay, Erool, Karavalum, Dud Eloopay, and Paulay.

The sleepers which had failed on the Madras Railway might be divided into two classes—those which were originally of perishable woods, and were, therefore, unfit for the purpose, and those which, although of good woods, had been cut from young trees, and not been allowed to stand till old enough. The first arose from want of experience of the nature of Indian woods, the second to the absence of a proper system of working the jungles. The conditions under which the sleepers were supplied to the railway company, either through native contractors possessed of capital, or by purchase direct from the wood-cutters or others, having been found to fail, the author suggested that in future the company should send their own agents, with sufficient establishments, into the jungle to cut down the wood, that the wood-cutters should be furnished with proper appliances, and their operations be carefully superintended. This was done in one or two instances on the Madras Railway with great success. In particular, from the Palghaut jungles Mr. Ross, one of the resident engineers, was able to furnish sleepers for nearly eight districts, while on other portions of the line the supply required for one district of 25 miles could only be obtained from a great variety of sources. But as the Indian jungles abounded in woods of too perishable a nature to allow of their being used plain, the author recommended that the sleepers should be creosoted on a much larger scale than had yet been attempted in that country, as those so preserved which had been sent from England answered admirably. The process had not yet been fairly tried in India, as only Saul, Teak, Soondry, Sissoo, and other hard close-grained woods had been submitted to it; while the cheaper, more easily procured, lighter, and more open-grained woods, had been neglected. English creosoted sleepers led, say, 100 miles by rail and 50 miles by road, cost 9s. 6d.

each; while good, native wood, plain sleepers delivered at the works, averaged 6s. each. If establishments and apparatus for creosoting were erected in convenient positions near to each extensive jungle, it was believed sleepers of common wood might be procured for 4s. 6d. each, and be creosoted for about 1s. each.

In proof that the resources of India were likely to be equal to the demand, reference was made to the Report of the Conservator of Forests for the official year 1859-60. From this it appeared that from the Salem Jungle alone—one probably of 20 in the Madras Presidency—about 246,000 sleepers, or sufficient for 133 miles of railway, had been cut during that year. Of this number about 62 per cent. could not be used plain, and were practically useless, owing to the want of artificial means for preserving those of a perishable nature. But as a supply from each jungle of 2,000 sleepers per month would provide for the construction of 500 miles of railway in that presidency within the next five years, and for a renewal of 33 per cent. of those already laid, it might be confidently anticipated that the supply would not fail, if means were taken to make the naturally perishable sleepers last a reasonable time.

In conclusion, the author recommended that a fair trial on a new footing be made with the native wood sleepers; that all woods now known, or hereafter found to be good, be used plain, and that others be avoided; that proper care be taken in the selection, felling, and seasoning of the timber; that the sleepers be tarred under the seats of the chairs, and that they may be laid in dry ballast, raised slightly in the middle, and sloped off, so as to throw the water under the rails.

It was announced that the discussion upon Mr. McMaster's paper, "On the Woods used for Sleepers on the Madras Railway," would be taken at the next meeting, Tuesday, February 10th, when, if time permitted, the following papers would be read:—"Description of the Drainage of the Borough of Dundee," by Mr. John Fulton; and "Description of the Drainage of Newport, Monmouthshire," by Mr. A. Williams, Assoc. Inst., C.E.

PROCEEDINGS OF THE INSTITUTION OF MECHANICAL ENGINEERS.

On the Manufacture of Hemp and Wire Rope.

By Mr. Charles P. B. Shelley.

Ropes are mainly constructed either of the fibres of the hemp plant (canabis sativa) or of iron wire. Other vegetable substances and other metal wires are also used; but in the present paper only the two important manufactures of hemp rope and iron wire rope are referred to: and as the treatment of the hemp fibres and manufacture of them into rope is quite different from the formation of iron wire rope, the subject naturally divides itself into two branches.

Hemp rope.—Of the other substances besides hemp which have been found useful and profitable for rope making, the most important are—"manilla," the fibres of which are obtained from the bark of a wild species of banana, grown in the Philippine islands, manufactured into a rope commonly known as "white rope;" jute, grown in Bengal, the fibres of which are used for adulterating hemp; cocoa-nut fibre for inferior ropes; Indian hemp, or "sunn," the high price of which however keeps it out of the market; and Spanish grass or "esparto." Of these "manilla" is the most common substitute for hemp. The machinery employed for manufacturing any one of these several fibres into rope is similar, with slight modifications, to that employed for hemp. The intestines, hide, and hair of animals are sometimes used for rope for special purposes; and the Romans are said to have formed ropes by binding together rushes (junci), whence the name "junk" for cable is believed to be derived. A variety of specimens of hemp and of other fibres, together with ropes of different makes, are exhibited, which have been kindly furnished to the writer by Messrs. Wright, of Millwall. The manufacture of hemp ropes is still carried on by hand, the ingenious machinery invented for the purpose by the late Captain Joseph Huddart, and for some time employed at Deptford dockyard, having been abandoned, and the old plan of hand making again reverted to.

The hemp plant from which the fibre is derived consists of a woody cylindrical stem, surrounded by a fibrous peel held together by a glutinous substance, the whole being protected by a fine epidermis or skin. The fibrous part, which is the portion used in the manufacture of ropes, is strong, flexible, and tenacious; but the woody core and the external skin are useless, and it is necessary that they shall be separated from the fibres. This is effected by "retting," that is by soaking the hemp stalks in water and allowing fermentation to take place, thus rotting the woody and glutinous parts and leaving the fibres free. The hemp is pulled up by the roots, and the flowers and leaves stripped off, and it is then immersed in a pond or running stream where it is allowed to remain until fermentation takes place, the time of immersion being dependent upon the degree of humidity and temperature of the atmosphere, and also upon the quality and growth of the stalks. There are many objections, however, to this system of retting; the principal is that the stalks not all being of the same strength of growth, and also occupying different positions in the immersed heap, some are liable to suffer from decomposition and be weakened while others may not be sufficiently steeped, rendering it difficult in the processes which follow to separate the woody matter from the fibres, and thus rendering the hemp harsh and inelastic. Another serious objection is that the vapour arising from the putrefaction of the stalks renders the neighbourhood of the stream or pond where the retting is carried on unhealthy. Moreover, this mode of retting unavoidably deteriorates and wastes the fibre; for a single stem of hemp is said to be composed of 70 to 80 per cent. of wood and 20 to 30 per cent. of fibre, whereas the fibre obtained by the present method does not exceed 16 per cent. and falls as low as 12 per cent., the remainder being wasted in the retting. Several other modes of preparing the stalks have been tried, such as steaming them, treating them with lime water or alkaline solution, and also adding materials to the mass of soaking stalks with a view of inducing speedy fermentation; but generally these plans have failed and there is still room for improvement in this respect. After the stalks have been dried they are broken at a hand break or by rollers, and the woody part is separated by "scutching," somewhat in the same way as in the case of flax. The hemp thus prepared is packed in huge bales, each bale of Italian hemp, jute, or manilla, weighing about 2½ cwts.

In order to form the strongest rope out of a given quantity of material, whether hemp fibres or metallic wire, the fibres should be laid parallel alongside one another and secured at the ends, so that they may take any tensile strain put upon them in the direction of their length; the strength of such a rope will be equal to the strength of each fibre multiplied by the number of fibres in the section. Hemp fibres rarely exceed 4 ft. in length, so that the above method of making a rope exceeding 4 ft. in length will not apply to that material. In order, therefore, that the fibres may be securely and continuously connected together, they must be placed parallel to one another, with the end of one fibre overlapping the end of its neighbour; and to prevent the fibres slipping from one another, friction is produced amongst them by twisting; but as the strength of the fibres is diminished when they are twisted out of the direction of the tensile strain which they are to sustain, no more twist should be given than is necessary to impart sufficient friction to prevent them from slipping and parting endways. It must be remembered that fibres of hemp, like metallic wires, have not the property of "felting," or uniting into one length by a kind of entanglement or matting together, in the manner common to the fibres of wool and other materials used in spinning. If a bundle of parallel fibres be twisted, those on the outer surface will be stretched and strained considerably more than those near the centre; and the further they are from the centre, the more will they be strained. Hence, in constructing cordage it is necessary to form or build it up gradually from small bundles. Thus the primary object of the rope-maker is to get the longest, finest, and strongest fibres which can be economically obtained; and next to lay them in bundles parallel to one another, and in continuous juxtaposition, giving them ultimately such a degree of twist that the friction amongst the fibres of the bundle is equal to their tensile resistance.

When the fibres are laid parallel and in continuous juxtaposition, they are said to form a "sliver;" and the sliver when twisted is said to be converted into a "thread" or "yarn;" and a number of yarns laid parallel and in juxtaposition, bound round by an external "serving" of yarn to hold them together, form "selvagee," which is the simplest construction of rope. If each of the yarns in the selvagee bore its fair share of strain, this would be the strongest kind of rope; but the objection to its more frequent use is that the outside "serving" of yarn frets away and allows water to enter and rot the yarns inside. In order to overcome the objections to selvagee, ropes are made of "strands," each strand consisting of a number of yarns twisted together, the strands being again twisted into the rope; the class of rope depends upon the number of strands and their arrangement. The yarn is twisted in the process of manufacture by a motion to the left from the right, or contrary to the motion of the hands of a watch, producing what is termed in rope-making a left-handed twist, being a spiral corresponding to the thread of a right-handed screw. The twist of each strand is in the opposite direction to that of the yarns composing it; and the twist of the rope itself is again in the opposite direction to that of the strands, or in the same direction as that of the yarns.

Ropes are commonly divided into three classes known as "hawser-laid," "shroud-laid," and "cable-laid" ropes. "Hawser-laid" ropes are composed of three strands twisted together; the number of yarns for each strand in different sizes of hawser-laid ropes is dependent on the diameter or number of thread of the yarn. "Shroud-laid" ropes are composed of four strands. "Cable-laid" ropes are composed of three hawser-laid ropes twisted together. "Cablets" are small cable-laid ropes measuring from 1 to 10 inches in girth; larger sizes are termed cables. Shroud and hawser-laid ropes seldom exceed 10 inches in girth. A core or "heart" is used in shroud-laid ropes; it is made of rope and is placed in the centre of the strands, running from end to end of the rope with the strands laid round it. In old worn out ropes the core is always found to be broken in consequence of the stretching of the strands; for the strands being twisted spirally and the core straight, the strands will give more under a load than the core, which cannot, therefore, be relied upon for adding strength to the rope; but it assists materially in keeping the strands in position during the manufacture of the rope by hand. Flat hempen ropes are made of four or six ropes, each composed of three strands, and laid alternately to the right and to the left; these are stretched side by side and sewn through in a zigzag direction.

Before the hemp is spun into yarn it has to be freed from dust and hard knots, and the fibres combed so that they may be separate and parallel to one another. This process is called "heckling," and is done either by machinery or by manual labour; the machinery for the purpose is similar to that used in the preparation of flax. When done by hand, each man is provided with two combs or "heckles," one coarse and the other fine. The heckle is formed of a number of straight sharp-pointed steel pins, fixed with the points upwards in an inclined board; the length of the pins, their thickness, and pitch or distance from centre to centre, vary with the material to be heckled, those used for manilla being much finer and closer together than those used for hemp; the pins for heckling hemp are about 10 in. long, and about 2¼ in. pitch centre to centre. The dresser, after untying and opening one of the heads of hemp, takes hold of the fibres at about the middle of their lengths and throws one end of them loosely over the pins, and pulls the bundle towards him; this is repeated until about half the length has been thoroughly combed by drawing through the heckles. The bundle is then turned end for end, and the other half heckled in the same way, after which it is finished on the fine heckles. The hemp is now entirely free from knots, and has a glossy, silky appearance; it is distinguished as "long hemp," and is said to be "topped;" and the handful of hemp is then doubled in the centre, and tied at the ends, in which state it is called "doll," and weighs about 2 lbs. The tow or fibres retained by the heckles are called "shorts," and if the shorts are to be worked into the yarn they are tied up into the bundle of "doll." The dresser applies a little oil occasionally to the points of the prongs, for the purpose of reducing the friction; and in dressing manilla, soap is sometimes applied to the fibres for the same purpose, in addition to oiling the heckles. Each bale of Italian hemp, jute, or manilla weighing 2½ cwts., or 280 lbs., loses by heckling about 80 lbs. of "shorts" and 10 lbs. of waste, leaving 190 lbs. of "long hemp" from the bale. One dresser heckles in a day 8 cwts. (finished weight) of St. Petersburg hemp, or 2 cwts. of manilla, or 1½ cwt. of jute.

The next process which the fibres undergo is that of spinning into yarns. Hand spinning is done on a long strip of ground called the rope walk, which is generally covered by a low roof; sometimes the shed has an upper floor with a low roof, and then the spinning is done on the upper floor, and the other parts of the manufacture on the ground. The length of the walk and shed is about 1,230 ft., or a little over 200 fathoms, and the width about 30 ft. The tie beams of the roof are placed every 30 ft. or 5 fathoms apart, and carry a row of hooks on the underside. That end of the walk at which the spinning machines are placed is called the "head" or "fore end" of the walk, and the opposite end is the "foot" or "bottom end" of the walk.

The hand spinning machine, shown in figs 1 and 2, is formed of two cast iron frames with a band wheel A between them, driven either by a man at the winch handle at the back or by steam power. A band passing round the wheel passes over twelve wood rollers or "whirls" 1½ in. diameter, as shown in enlarged view, fixed on steel spindles about ½ inch diameter, which revolve in notches or bearings in the brass discs C screwed in the frames of the machine: the spindles are kept in their bearings by a riband of wrought iron screwed upon the outside of the frame. On the back end of the spindle is a shoulder, and between this and the brass disc is a loose collar, to take the pull of the yarns in spinning; the spindle is kept in by a finger D fixed on the back of the frame. The front end of the spindle is drawn out into a hook E. The notches are for the purpose of forming fresh bearings for the spindles; there are eight notches in each brass, and when one notch is worn down the brass is turned to bring another notch round: when the whole of the notches are worn down a new brass is put in. The twelve hooks and "whirls" are set upon the semicircular upper part of the machine, and are made to revolve by the band which passes over them from the driving wheel A.

Each spinner, before beginning to spin, takes up a bundle of hemp, sufficient in quantity to spin one "thread" of yarn of the required length; he places the "bight or middle of the length of the fibres in front of him, and turns the ends round his waist, crossing them behind. If the "shorts" are to be worked into the yarns they are tucked below the bight. Each spinner carries in his right hand a piece of stout list. There are twelve spinners to each machine, one to each hook. The spinner draws from the bight or front of the bundle round his waist a sufficient quantity of fibres for the size of the yarn or thread about to be spun, then forming a "sliver," which he twists with his fingers, and hooks the bight of the sliver on to one of the revolving hooks of the machine. He then walks backwards towards the bottom of the rope-walk, drawing the hemp from his waist, and forming a sliver with his left hand, pulling some of the fibres back if they come forward too quickly, and drawing some forward if there are not enough to keep up the required size of yarn. The sliver passes through his right hand, with which, by means of the piece of list, he firmly gripes it, so as to "form" the yarn. The spinner thus prepares the sliver and forms the yarn, while the machine gives it the twist. Care must be taken not to place the ends of one set of fibres too near to the ends of the next set, not giving them sufficient lap, otherwise the yarn will part by the fibres, slipping endways from one another; and also to keep the fibres even and regular in thickness, in order that the yarn may be of equal strength throughout. The spinner's pace in walking backwards must be uniform and in accordance with the speed of the revolving whirls. The speed of the whirls and the amount of twist of the yarn is dependant upon the quality of the rope to be manufactured.

HEMPEN ROPE MAKING MACHINERY.

FIG. 1.

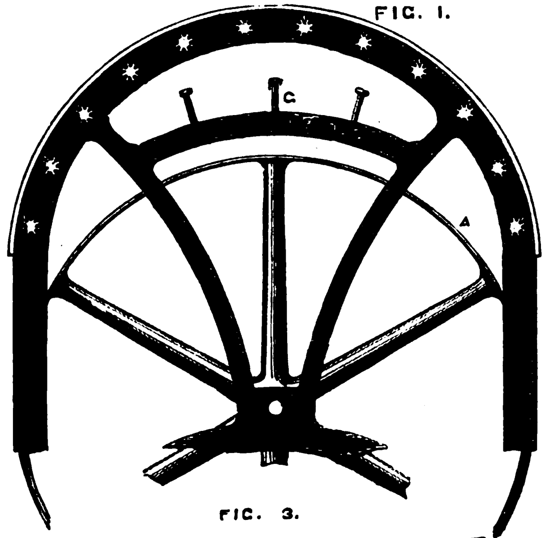

FIG. 2.

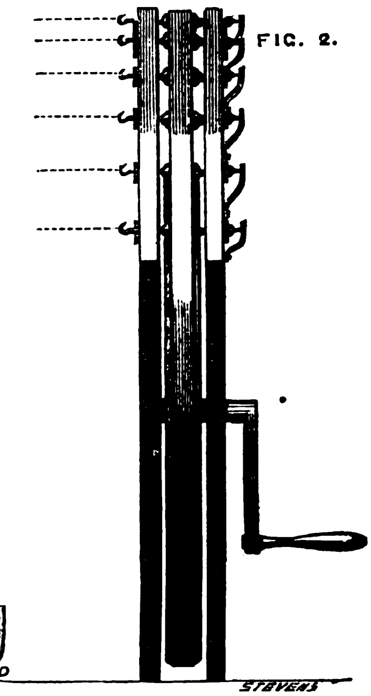

FIG. 3.

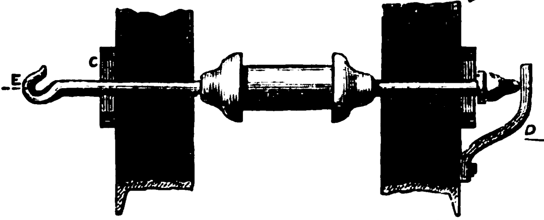


The twelve spinners are divided into three sets of four each; four risers, four middlemen, and four leaders. The four risers work from the four hooks on the left side of the machine, the four middlemen from the four middle hooks, and the four leaders from the four hooks on the right of the machine. All the twelve spinners start at once from the machine in the morning. The four risers spin down the walk a yarn 1-3rd of 160 fathoms long, and then stop, while the middlemen and leaders continue to spin past them. The four yarns of the risers are now unhooked from the whirls by a man at the top of the walk, and are passed each through a hole F in the frame of the spinning machine, fig. 1, to a reel at the back, upon which they are wound; the men at the bottom end of the yarns still hold on so as to prevent the yarn from untwisting, and follow it up to the machine as it is wound on to the reel. They then twist the ends of these yarns on to one of the holding pins G, on the cross bar of the machine frame, and start spinning again with four fresh yarns which they will this time spin down to the whole length of 160 fathoms before stopping. The four middlemen spin down the walk a yarn 2-3rds of 160 fathoms long, and then stop, while the leaders still go on and pass them. Their four yarns are taken off the hooks of the machine and spliced on to the ends of the four yarns which were left on the holding pin by the risers; the yarns of the four middlemen are then wound on to the reel, the men following them up the walk and fastening the ends on to one of the holding pins: the middlemen then start fresh yarns of 160 fathoms length, and spin down the walk. The four leaders spin down the walk a yarn 160 fathoms long, and then they also stop, and their four yarns are taken off the hooks and spliced on to the ends of the four yarns left on the holding pin by the middlemen; the yarns of the leaders are then wound up on the reel, followed up by the men. So they go on till breakfast time, the three sets of men never being up at the machine together, and never more than four being there at one time, so that the three sets are always separated. After breakfast the risers commence with 2-3rds lengths, and the middlemen with the 1-3rd lengths, and thus the quantity of yarn spun is equalized between them.

(To be continued.)

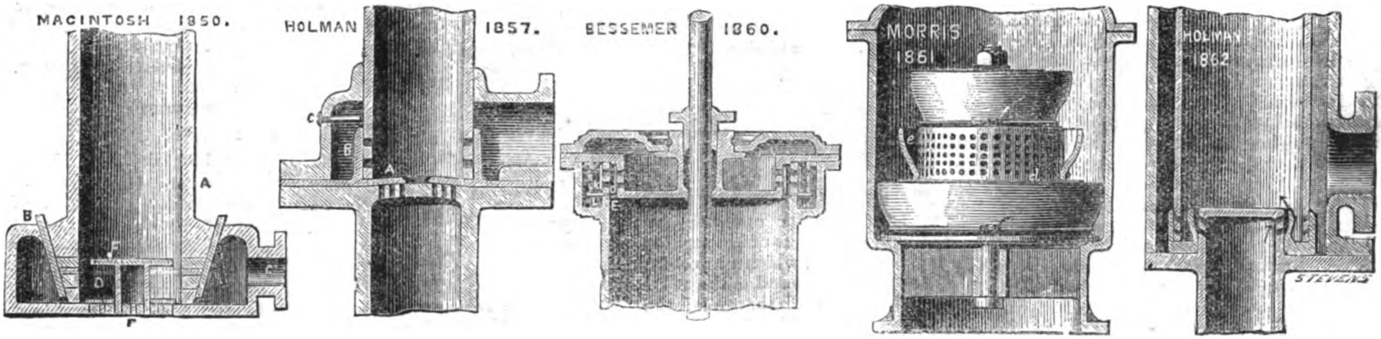
INSTITUTION OF MECHANICAL ENGINEERS.

THE sixteenth annual general meeting of the members of this Institution was held on Thursday, the 29th ult., at the house of the Institution, Newhall-street, Birmingham; **CHARLES F. BEYER**, Esq., Vice-President, in the chair.

The SECRETARY (Mr. W. P. Marshall) having read the minutes of the previous meeting, the annual report of the Council was then read, which showed the very satisfactory progress of the Institution during the past year, and its prosperous condition, with a considerable increase in the number of members, referring also to the large and important special meeting held in London last summer during the period of the International Exhibition. The annual election of officers then took place, Robert Napier, Esq., being elected President of the Institution for the the ensuing year; several new members were also elected.

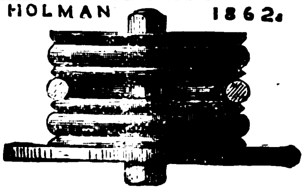
The first paper read was a "Description of the Apparatus used for Sinking Piers for Iron Railway Bridges in India," by M. JOSEPH F. STRONG, of Allahabad. The mode of sinking the piers described in the paper is an extension of the plan long in use among the natives in India for sinking wells and forming foundations for river forts and quay walls to the sandy ground, by building a well or cylinder of brickwork, and

HOLMAN'S PUMPS AND VALVES.



excavating the sand from the interior, so as to allow the cylinder to sink by its own weight until it has obtained the required hold in the ground, the sand being excavated by divers with a scoop called a "jham." The extent to which this plan can be carried out is therefore determined by the limit to which the native divers can execute the work, each one remaining under water about a minute at a time without any diving apparatus. In the application of this plan to the foundations of railway bridges, where a much greater depth and size of well are required a scoop of larger size, and worked entirely from above water, is employed. This is lowered inside the brick well, with its front cutting edge downwards, and is forced down into the sand by being lifted and dropped a few times with the weight of several men acting on a long pole inserted in a socket at the back end of the scoop. The scoop is then hauled up by means of a chain attached to an arm projecting in front, which tilts the scoop and draws it through the sand into a horizontal position; and the scoop full of sand is then drawn up out of the well by the windlass. The brick cylinders are built upon wrought iron kerbs at the bottom, and sink gradually by their own weight, as the sand is excavated from their interior; and successive lengths of brickwork are added above the water, until the required depth of about 43 ft. in the ground is reached. Ten cylinders are sunk together to form a single pier, being afterwards filled up solid inside with concrete and rubble stone, and also between the cylinders above the ground level, so as to form one compact mass of masonry for the foundation of the pier. For the purpose of pitching the iron curb in the first instance for building the brickwork upon, in places where the bed of the river is always under water, an artificial island is temporary formed on the proper site by throwing down sand bags in the river, and filling in sand on the upper side of them till the surface of the water is reached. This is the mode of sinking piers that has been carried out on the main line of the East Indian Railway, in the construction of the iron bridge over the River Jumna, at Allahabad, near its confluence with the Ganges. The bridge is composed of sixteen openings of 205 ft. clear span each, crossed by wrought-iron girders, and the brick cylinders are sunk to the depth of 43 ft. in the sand before being filled in with the concrete. The river is only about 12 ft. deep at low water, but rises 45 ft. higher in flood time.

The next paper was "On a Type Composing and Distributing Machine," by Mr. **William H. Mitchel**, of London. In the composing machine the types are ranged in parallel reservoirs placed nearly vertical, from which they are conveyed to the setting-up wheel by means of a series of parallel endless bands, one to each type, and a diagonal collecting band, upon which the several types are delivered successively by the parallel bands. The diagonal band is driven at a higher speed than the parallel bands; and this difference in speed of the bands neutralizes the effect of the different distances at which the several type reservoirs are situated from the common point of discharge on to the setting-up wheel, which would otherwise cause the type from a nearer reservoir to reach the wheel sooner than one from a more distant reservoir, although the latter had been first started. The total time of travel of every type from the type reservoirs to the setting-up wheel is thus rendered the same, whatever be the distance over which the type has to be carried in the machine; and the types are consequently set up in the exact succession which they are played out from the type reservoirs. The selection of the types by the compositor is performed by a row of finger keys, one key being appropriated to each type; by the depression of any key one of the corresponding types is liberated from the bottom of the type reservoir containing that letter, and dropping on the travelling band beneath is conveyed by it to the setting-up wheel. The types fall into notches in the circumference of this wheel, which is a racket wheel like a circular saw revolving backwards; they are carried round by the wheel into a vertical position and set up one after another in a row, which is pushed forwards successively by the revolution of the setting-up wheel, advancing through a distance equal to the thickness of each type that is added; the whole row slides securely in a groove until the required length of type is set up, which is then removed by hand and justified and corrected in the ordinary manner. In the event of two types being accidentally played out simultaneously, so as to reach the setting-up wheel together, one of them is thrown out laterally, and falls clear of the wheel without injuring the machine or stopping its action. The machine is capable of composing at the rate of six letters per second, but its speed is practically limited by the skill of the operator; one machine is capable of employing two compositors. In the distributing machine the separation and distribution of the different types is accomplished by means of nicks, one, two, or three in number, made in the edge of each type, the size and position of which are different in every type. The line of letters to be distributed is ranged in a long feeding groove, and brought up against an inclined stop plate, which fits into the highest of the nicks in the foremost type; and the width of the nick being proportional to the thickness of the type, the advance of the line of letters is thereby determined according to the thickness of the foremost letter, so that the back face of each letter is brought up exactly to the same line when it comes to the end of the feeding groove, and thus not more than one letter at a time can be cut off for distribution. The foremost letter is then cut off by a vibrating striker, and drops into one of the grooves in the circumference of the distributing wheel revolving horizontally beneath the striker. In this grove the type remains suspended hanging on a projecting pin which catches the lowest of the nicks in its edge; and is carried round by the distributing wheel until its foot encounters one of a series of inclined stops fixed at different levels on the table of the machine, whereby the type is thrown off the suspending pin and drops into the receptacle appropriated to that particular letter. In the case of types having a second distributing nick, the first or lowest nick is cut nearer to the bottom of the type, so that while suspended at this first nick the foot of the type is kept high enough to clear all the stops in the first class of inclines, and the type is carried forward to a second, third, or fourth class of similar stopped inclines, according to the height of the lowest nick above the foot of the type; and being thrown off the suspending pin by a projection at the commencement of its own particular class as it then descends as far the second nick in its edge, by which it is carried back still further on the suspending pin until its foot meets the individual stop belonging to it in the class, when the type finally drops off into its own receptacle. The nicks in the types are readily cut with great accuracy by a kind of plane, which cuts all the nicks simultaneously in a long row of type of the same letter. A stop action is provided, to stop the motion of the distributing machine by a self-acting arrangement, in the event of any type accidentally sticking in the grooves of the distributing wheel. The machine distributes in regular work eight thousand letters per hour, and requires only the attention of a boy. The composing and distributing machines, which were shown in working order, are each constructed to take forty sorts or letters, including all the letters required in the general run of printing work of a regular description. The extra sorts, such as small capitals, italics, numerals, &c., are put in by hand in the composing machine, and are afterwards distributed also by hand, being rejected by the distributing machine, since they do not contain the suspending-nicks, by which the distribution is effected in the machine. Several of the composing and distributing machines have been in use for some years, and are working successfully.



The meeting then terminated. In the evening a number of the members and their friends dined together, in celebration of the sixteenth anniversary of the institution.

HOLMAN'S PUMPS AND VALVES.

Sir,—Doubtless some of your readers are readers also of the *Engineer*. I beg permission, therefore, to correct a statement which appeared in my specification published in the *Engineer* of last week, as it is likely to do me considerable injury. I am more desirous to do so as the patent was inserted in the Mechanics' Magazine at the same time. The statement referred to runs thus:—"Valves of the construction shown were patented by Mr. Bessemer about three years ago." To save time I hand a copy of my reply to the foregoing statement, together with a duplicate of the illustrations.

I am, &c.,
Stephen Holman.

To the Editor of the Engineer.

Sir,—The paragraph which you imported into my specification published in the *Engineer* of last week affects me personally, and many others commercially. I claim, therefore, to reply through the same medium in self-defence, and in the interest of my clients.

I cannot for a moment suppose there was any intention to serve Mr. Bessemer at my expense, and in this case at least there would be no charity in "robbing Peter to pay Paul." I notice, however, a remarkable coincidence. viz., the omission of the following important paragraph :—" In this pump I leave myself free to use the flexible cylindrical valves according to my specification, dated 16th June, 1857, No. 1679, or the disc valves as frequently used in pumps, or new valves and seats made according to the following description in the second and third parts of this invention."

I hope to show by the assistance of the accompanying illustrations, that the above cited paragraph should have appeared in its proper place, and that the following indefinite and mischievous statement was an unhappy substitute for it, viz.: " Valves of the construction shown were patented by Mr. Bessemer about three years ago." Now, it would have been some mitigation of the evil (seeing there are two distinct kinds of valves in my patent) if you had qualified your assertion by giving reference to fig. 7 in the illustration, as that is the only valve to which Mr. Bessemer's bears any resemblance, and seeing that that valve occupied only a secondary position, both in my specification and drawing.

The illustrations of the various valves herewith give their history, as far as I have had an opportunity to trace it. The valve first on the list is by Messrs. Macintosh and Co.; I mean by this, that it was published by Messrs. Macintosh, as long ago as the year 1850, probably before. I enclose you their illustrated list, and am sorry I cannot at present give you the name of the inventor. The single cylindrical strap ring valve, with its perforated seat, is there shown, together with a separate disc valve for the suction or inlet. My valve of 1857, the second on the list, is a compound valve which accords with the following extracts from my specification, No. 1697 :—" The chief object of this invention is to simplify the construction of force pumps, by applying thereto an elastic compound valve, in place of the ordinary arrangements of clack and other valves. This valve is formed of a cup of vulcanized india rubber, which is applied to the lower end of the pump cylinder between it and the inlet pipe, so that its bottom covers the inner end of the pipe, while the lip or upper part of the cup surrounds and lies closely against the cylinder, which is pierced at that part with holes for the discharge of the water from the cylinder. In the bottom of the cup a tongue is cut or stamped out, so as to form a clack valve, which will be free to rise when pressure is put on its under side, and to close when the pressure is removed or reversed. When by the repeated strokes of the piston in the cylinder, the water has been drawn up through the inlet pipe, the piston descends and forces the water through the later openings in the cylinder, the elastic material surrounding the cylinder yielding to allow of its passage. An obvious modification of this improvement will be a ring of india rubber, with flanges at right angles, or nearly so; the inner lip or flange shown at A will then form an annular valve like that which surrounds the cylinder shown at B, and closing openings made in the closed end of the feed pipe, will act like the clack valve before described; this cup or ring may also form a packing for the joint between the cylinder and its supply pipe."

The distinguishing feature of this compound valve is that it comprises both suction and delivery valve in one piece of material; and, as shown in the illustration, the fluid is admitted to and discharged from the barrel through perforated seatings.

Permit me to refer next to Mr. Morris' valves, the fourth on the list (as that appears to be the next of our acquaintance); these appeared in the *Engineer*, under date Sept. 20, 1861, and are single flat band valves secured at one edge and provided with perforated seatings as before described. You did me the favour to insert a letter in the *Engineer*, under date Oct. 4, 1861 (a fortnight afterwards), and as bearing upon the case in point I reproduce it, viz.:—

" *To the Editor of the Engineer.*

" Sir,—Observing the specification of Morris' valves in the *Engineer*, under date Sept. 20, 1861, I hand you a copy of my specification left at the Patent Office on the 16th June, 1857, No. 1,679, which establishes a prior introduction. These valves have been in use for the last four years in London, in some cases confined at the bottom, so that the upper part only is permitted to open for the discharge of the fluid; in others the ring of vulcanized india-rubber is free both at top and bottom, so that the valve may expand in a parallel cylindrical form, instead of being compelled to assume the conical form by reason of its being confined at either edge.

In the latter case, the valve is prevented from shifting out of its position by guard studs (shown at C), which project from the annular seat beyond the spread of the valve, when opened by and for the discharge of the fluid. I think it judicious to offer these remarks, so that Mr. Morris (whom I have the pleasure of knowing personally) and the public may not consider me infringing Mr. Morris' claims in my future use of the valves. " S. HOLMAN, C.H.E."

" 18, Canon-street, E.C."

A further reference to these valves was made, in the *Engineer*, dated Oct. 24, 1862, under the head of " Invalid Patents." The pump valves patented by Mr. Morris, of the Kent Waterworks, (No. 323) 1861, has been provisionally specified by Mr. S. Holman, in 187 No. 16579 :" thus you had three previous opportunities of mentioning Mr. Beesemer's patent, at either of which it would have been much more appropriate than in my specification of 1862. Mr. Bessemer's valves, as shown in the third illustration (being the third in the order of date), are the single flat band or strap valves; D is the inlet valve, and K the outlet valve. The valves being perfectly free throughout the depth, are kept in their position by guard studs at E and L; this mode of securing the valves is also mentioned in my letter dated September 20, 1861, given above. Mr. Bessemer's arrangement, as shown in the illustration, was with the view of forcing air entirely, and formed only a moderate portion of his famous scheme for the manufacture of malleable iron and steel. I read his specification, for the first time, on Saturday last, and shall never forget the ingenious way in which the air is admitted to the barrel by passing through the annular channels. I confess frankly that was a perplexing point to me, and led me ultimately to adopt the inserted barrel with the continuous delivery passage, common to both delivery valves. (Excuse this incidental digression from the immediate case in point. My admiration of Mr. Bessemer as a public benefactor, and my obligation to him as a patron in business matters, makes me regret that an ill-timed use of his name has rendered it necessary for me publicly to defend my patent right. I come now to illustration No. 5 on the list, which I presume is the one you thought analogous to Mr. Bessemer's valve. That, however, is a compound valve, combining inlet and outlet valve in one piece of material. I beg permission to state how I conceived a valve of that form to be practicable. It will be obvious that if a plain internal barrel is fitted with compound valve (as shown) at each end, that any pressure exerted by the cover would cause the barrel to be indented in the bottoms of the cups, if they were of the same flexibility at those parts, as they must necessarily be at the parts covering the perforations. Messrs. Warne and Co., a-year or two since, introduced their " Junction Rubber," the peculiarity of which is, that it may be made to any degree of hardness at one part, and flexibility at another; hence my application of it in the manner shown, and for the purposes described in my specification. Moreover, I could not possibly have been ignorant of the single band valves to which you allude. Just a word in reference to the valves as per illustration, No. 6; they are totally different in form to any of the others mentioned, and are provided with different seatings and water discharges, and seeing they formed a prominent feature in my specification, they ought to have been screened from the damaging influence of your vague assertion, which would appear to apply to all alike. I therefore beg to affirm that, " valves of the construction shown" were never patented by Mr. Bessemer at all.

I am, &c.,
STEPHEN HOLMAN.

18, Cannon-street, E.C.

SUBMARINE TELEGRAPHY.

ON the 28th of January last, Mr. T. A. Masey read an interesting paper before the Society of Arts. As our readers are familiar with most of the facts stated in the paper, we will not give it in full. The following is the concluding portion of the paper:—

I have now briefly reviewed the subject, but I have a few words to say about the proposed cables and telegraphing to America or elsewhere without the aid of wires at all. Hundreds of patents have been taken out for different kinds of cables, but the original spiral form of twisted wires for the outer covering, first adopted by Mr. Brett, still keeps its ground. It is impossible to say what form of cable will be adopted for the new Atlantic line; but no doubt every experiment and trial will be carefully made, and no expense spared to arrive at a satisfactory result; and when a suitable cable has been decided upon, and a careful supervision given to its manufacture, there can be no doubt that it will be successfully laid. Amongst other new inventions is that of Mr. Duncan's Ratan cable, which he advocates upon the grounds of its flexibility without elasticity, of its being imperishable in water, and of the cheapness at which it can be manufactured.

Another form of cable, containing some new combinations, has been adopted by the Indian Government for their cable of 800 miles down the Persian Gulf. The novelty which it possesses is in the manufacture of the copper wire, which is a single wire instead ot a strand of several, so much advocated, as affording great additional strength, and avoiding the possibility of a total fracture at one particular spot. But a strand has this disadvantage—that if one wire breaks, the sharp points are liable to start out and pierce through the gutta-percha. Want of solidity is also urged against a strand, as it is alleged that if water penetrates in any place to the wire it will pass along the wire as in a tube. To remedy this defect, the Gutta-percha Company propose to coat the central wire of the strand with Chatterton's compound, and bed the wire in it during the process of twisting.

Mr. Daft proposes to obtain the same object by bedding copper wires coated with brass in vulcanised india-rubber.

Mr Varley proposes using three or more insulated wires joined together at different distances. If any one wire (or two wires) be exposed by injury to the water, the current will eat it away, and thus increase the resistance of the escape without increasing sensibly the line; the more the wire is eaten away the better the cable becomes. Such a cable may be defective in twenty places, and yet work perfectly.

Mr. Newall unites the several wires of a strand with solder.

Mr. Latimer Clark, who, with Sir Charles Bright, are appointed engineers of the Indian Government, proposes to obtain this solidity by making the conductor in the shape of a solid wire, divided into three or four sections, longitudinally fitted, and rolled into each other, and they have adopted this form in the Persian Gulf cable now being manufactured by Mr. W. T. Henley.

The outside covering of iron wire is the old form, but it also is now coated with hemp, and a tarry composition to protect the iron from rusting, a plan which will be universally adopted in future after the experience gained with the Atlantic and Red Sea lines.

But while various parties have been at work devising new cables, another gentleman, a Mr. Haworth, has been at work to discover a means of conveying electric signals without any wires at all. He has taken out a patent and filed drawings of the apparatus, but I have not met one single gentleman connected with the science of telegraphy who could understand his process of action, or its probability of success, although the theory is an old one. I applied to him for some information relative to his experiments, but he is unwilling to communicate any particulars until the success of his plans has sufficiently demonstrated their practicability.

With respect to the comparative merits of gutta-percha and india-rubber, I may remark that one of the earliest substances used for insulating purposes was india-rubber, but owing to the difficulty of efficiently covering the wire, and from the oxidation which took place when it was exposed to the atmosphere, it fell into disuse after the introduction of gutta-percha; and, although universally admitted to contain insulating properties, far above any other substance, no attempts, I believe, were made for several years to perfect it for telegraphic purposes.

Messrs. Silver have, however, in the last few years, turned their attention to the subject, and have been rewarded by producing a substance called ebonite, which is being universally used for various insulating purposes.

They have also arrived at a perfection not hitherto obtained in covering wire. A mile length prepared by the Messrs. Silver, was submitted to the Government Scientific Committee, and reported on by them as containing the highest insulation ever attained.

They state in the report—"That india-rubber suppasses all other materials in the smallness of the amount of its inductive discharge, and the perfectness of its insulation." Although this testimony carries great weight, yet the substance itself has not hitherto proved very durable, nor has it been adopted to any great extent, but the manufacturers are sanguine enough to believe that, with the present and other improvements which may be made, it will one day surpass everything else.

As regards gutta-percha, no vegetable substance has yet been discovered which presents the same advantages to the electrician as this gum. Its many valuable properties are too well known to mention; suffice it to say, that it has never been known to decay under water, and, as far as experience goes, it may, in that case, be said to be indestructible when suitably protected. The manufacture of the article has now arrived at a perfection to leave nothing to be desired but that the supply may not fail.

At a recent repairing operation in the case of the Belgian cable (made by Mr. France, the Submarine Company's engineer), and which was broken by a ship's anchor, it was found that, although the large iron wires of the outer covering were broken, as well as the internal copper conductor, yet so tenacious was the gutta-percha, that it resisted the enormous strain, allowing itself to be literally drawn out from the thickness of a piece of maccaroni to an attenuated shred of vermicelli, thus adding another fact to those already established of its indestructibility under water, and its superiority over all other insulating materials for submarine cables.

The Submarine Telegraph Company liberally offered the use of their wires to connect the society's rooms this evening with all the capitals of Europe, but, upon applying to the engineer to make the necessary arrangements, it was found impracticable, without great difficulty and expense, owing to the wires of the company being laid under the roadway in the Strand.

I regret this very much, as I had anticipated repeating an experiment which I witnessed some time since, namely, that of sending a telegram over the longest distance of land, and through the greatest extent of sea that was then possible. The experiment was so wonderful and interesting that it will bear relating, as showing what can be accomplished by the aid of electricity, although it does not refer immediately to the Atlantic cable.

A continuous wire was joined up from London to the island of Corfu, a distance of nearly 2,000 miles, but as the wire had necessarily to be suspended from hundreds of poles, extending over such a great distance, and where, perhaps, at every connection a small amount of electric fluid would escape, the charge would not last out to reach its destination without some additional assistance on the road. It, therefore, becomes necessary in such operations to refresh and invigorate the lighting, as in the old slow time a man would water his horses on the road, or as the Brighton "Age" would, in its then wonderful journeys, "change horses in half a minute."

To provide this assistance, instruments called "relays" were placed at different intervals along the line, the object of which was to receive the nearly exhausted current of electricity, revive it instantaneously with additional strength, and send it on to the next relay, and so on till it arrived at its destination.

In order to fully realise this wonderful achievement, we will trace the progress of a message along the route from London to Corfu.

The transmitting instrument in connection with the battery generating the electricity is set in motion. A flash of electricity is liberated, and wings its way along an insulated wire, under the busy streets of London, and under the now quiet turnpike roads to Dover, then under the surging waves, through the submarine cable, peacefully lying at the bottom of the Channel, to Calais, where it mounts up to land again, traverses the intermediate country to Paris, picks up a relay of electricity charged from a local battery in waiting to revive its now languishing strength, and, re-invigorated, pursues its silent and instantaneous flight through cities and towns without stopping, but every now and then receiving assistance and new life, till it arrives at Turin; thence on to Genoa, from whence with increased power it dashes through the submarine cable, 100 miles in length, to Corsica, rushes over this island in the quickness of a thought, descends again into the sea, across the Straits of Bonifacio to Sardinia, up on land again, through villages and over the Gallura Mountains, where the deadly malaria fever lurks that killed so many men in its construction, to the easternmost point of this island; then again taking a header through another submarine cable lying at the bottom of the deepest part of the Mediterranean to Malta, over its rocky ridges to the other side, from whence it finally flashes through another submarine cable under the sea to its destination, Corfu, doing the whole distance of 2,000 miles in two seconds and-a-half, and passing over, in its transit, some of the highest mountains in Europe, as well as five times descending more than a mile's depth into the ocean.

But the coming back of this mysterious agent is still more wonderful than its guided transit along the wire; for there it has an operator, philosopher, guide, and friend to direct its course; but now it returns home again, not along a conductor supplied by man's ingenuity, but alone through the earth. "The world is all before it where to choose," for after it has reached its destination, and recorded its symbolic mission, it is transmitted down a wire, sunk in the earth for that purpose, to find its mysterious way back to the spot from whence it started, and passes up another wire similarly placed in the ground, again into the presence and power of the operator; for, until it has arrived at home, the electric circuit is not completed, and no signal is given.

Wave after wave of electricity was transmitted, until the whole message of some twenty words had been communicated to the island of Corfu, the transit of the whole occupying three minutes; then a brief interval, and click, click, the serpentine length of paper unwinds itself, containing the reply, which came back in even less time than the message sent.

Having now briefly reviewed the subject of submarine telegraphs generally, and the Atlantic in particular, with some, I trust, pardonable digressions, I shall proceed to sum up my conclusions in as few words as possible.

1. First, then, with respect to the original cable, I cordially acquiesce in the resolutions arrived at by the committee appointed by the Board of Trade, that "the failure of the enterprise was to be attributed to the original design of the cable having been faulty, owing to the absence of experimental data; to the manufacture having been conducted without supervision; and to the cable not having been handled, after manufacture, with sufficient care.

2. That intercommunication between the old and the new world, by means of an Atlantic telegraph, is not more desirable than feasible.

3. That the accidents which befel the first cable arose from causes which there is every reason to believe will not occur again.

4. That the improvements in the process of manufacture of the cable itself, as well as of the insulating medium, have greatly enhanced the value of both, and in the latter case to an extent of 10 to 1, as compared with the insulating medium of 1857.

5. That we are no longer exposed to the mercy of the elements in the matter of laying and paying out the cable, as on the previous occasion, the "Great Eastern" having obviated the serious danger and difficulties hitherto experienced from the pitching of vessels employed in these operations, and by which, through the strain upon the cable, success was rendered highly problematical.

6. That the above conclusions are borne out by the liberal proposals of those eminent and successful cable manufacturers, Messrs. Glass, Elliott, and Co., to which I have before alluded.

7. That recent experiments fully demonstrate the possibility of working a one-wire cable commercially; but that it will be cheaper in the end for the Atlantic Company to lay a cable consisting of, at least, two if not three wires, because there will be such an influx of messages both ways, that, if a one-wire cable only is laid, telegrams will have to wait two or three days before they can be sent. The chances of success would also be greatly enhanced by having more than one wire.

8. That of all the various routes contemplated, that between Ireland and Newfoundland presents advantages superior to any other.

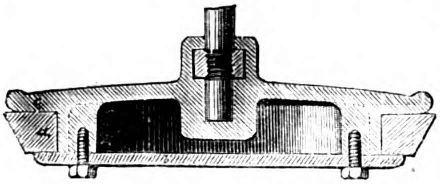
9. That considering the issues at stake, the present state of the science of telegraphy, and the fact that it has already interfered to point out the causes of the former failure, and the remedies to be adopted in any subsequent undertaking, Government might reasonably be called upon for another grant, at all events, to perfect the experiments necessary in a second and successful attempt to lay down the Atlantic telegraph.

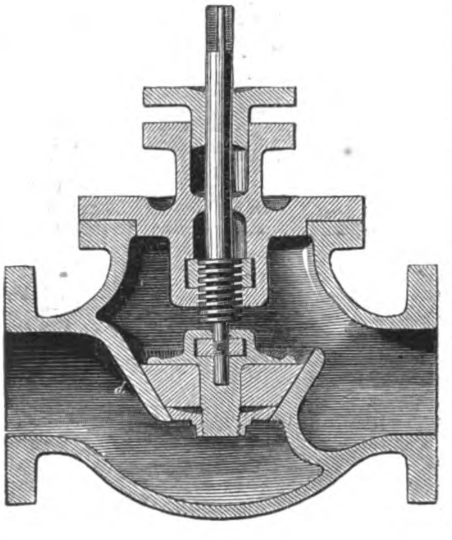
10. That the time has fully come when that attempt should be prosecuted in the interests, not only of science, commerce, and social economy, but also from a regard to the still higher interests of civilization and humanity.

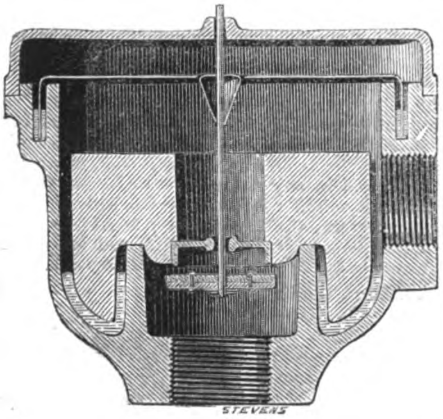
In conclusion, I indulge a fervent hope that those who have sacrificed so much already, and who, nevertheless, are prepared to risk still more to carry out this great work, may in the end reap the full reward of all their noble enterprise. Should, however, that pecuniary reward be wanting, of this I am well assured, that the consciousness of being pioneers on the high road to peace and amity among the nations of the earth, and, above all, between the different families of the great Anglo-Saxon race, will be to them a source of satisfaction, alike deep and permanent. I shall only add the expression of a wish, in which I am certain all here will join, that our kindred across the Atlantic, diverted from scenes of fratricidal strife and bloodshed, may ere long turn their thoughts back again to such subjects as I have been discussing this evening.

Voltaic Batteries for Steamers.—The Emperor of the French is now superintending the construction of one of these batteries, intended to replace fuel. In this country, it has been proposed to our Admiralty to make a trial of a voltaic battery of 2,000 double plates, each containing 30 square inches, the whole surface being 128,066 square inches. Charcoal points, connected with the two poles, are ignited to whiteness; on withdrawing the points from each other, an arch of light, 4 in. in length, is produced between them. When any substance is introduced into this arch, it instantly ignites. Platinum melts as readily as wax in a common candle. Quartz, the sapphire, &c., with equal facility.

TAYLOR'S GAS AND WATER VALVES.





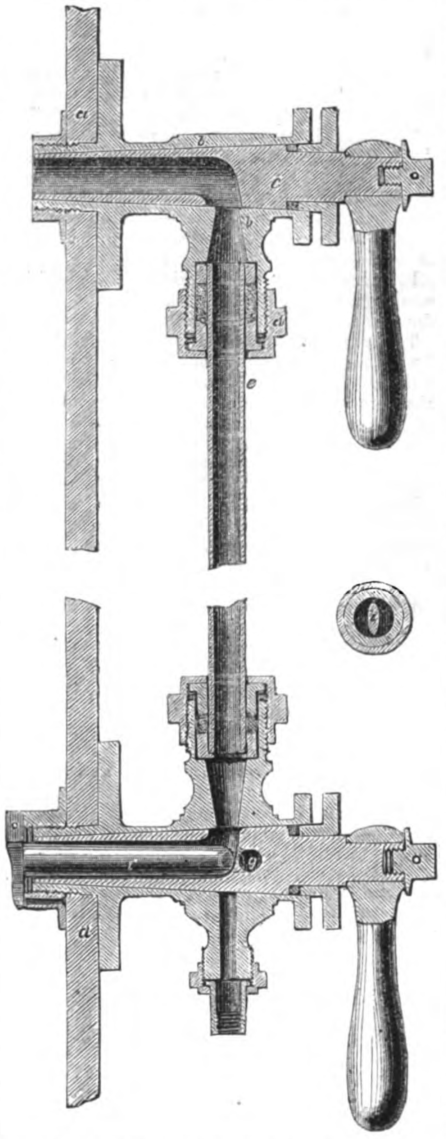


TAYLOR'S PATENT VALVES.

MR. J. W. TAYLOR, of Newsome, York, has patented an invention for improvements in valves, which consist in forming the plugs thereof of india-rubber, such plugs being secured by screw nuts or other suitable means between flanges or washers to the spindle. The accompanying engravings show the invention applied to a tap of the ordinary construction. *a* is the india-rubber plug held between the flanges *b* and *c* ; the plug is formed conical on the outside to fit a seat, *d*, of a corresponding shape, as shewn.

Another part of the improvements relates to apparatus for regulating the pressure and flow of gaseous fluids. The gaseous fluids pass through a chamber having a cover, which is capable of being weighted to the desired pressure, and has a rim projecting downwards into a trough of mercury by which such cover is capable of being lifted without permitting the escape of the gas, as is clearly indicated in the lower figure. The gas passes into this chamber by a passage regulated by a valve suspended from the cover referred to, and this passage is formed in a block with a surrounding edge also dipping into a channel of mercury. By this arrangement of the parts in the event of any derangement they are readily repaired and replaced.

HOWAT'S PATENT WATER GAUGE.



HOWAT'S PATENT WATER GAUGE.

THE annexed engraving illustrates, in sectional view, a water gauge recently patented by Mr. A. Howat, of Farnworth, Lancaster. This invention consists in constructing the plugs of water gauges and blow-off taps with a longitudinal groove or with a scraper, the edges of which, when the plug is turned partly round, scrape and loosen the sediment which may have collected in the body of the tap or in the plug.

a represents a portion of the boiler or other vessel, to which the water gauge is applied ; *b* is the body of the upper tap, which is furnished with a conical plug, *c*, the smaller end of which is towards the boiler, and with a union-joint, *d*, for securing the upper end of the glass tube, *e*, in the usual manner. The body of the lower tap, *f*, is also provided with a conical plug, and with a union-joint, for securing the lower end of the glass tube in the usual manner. The taps are attached to the front of the boiler by nuts as usual ; to the bottom tap a scraper, *i*, is attached, which enters within the plug, as shown in the figure. The upper plug is made with a passage, as shewn, to admit steam from the boiler to the glass tube, *e*, and the lower plug is made with a cross passage, *g*. When the plug is turned one-fourth round, the water out of the glass tube and the steam may be blown off; and when the plug is turned half round, the water alone is blown off through the ordinary passage. Whenever the lower plug is turned partly round, the sediment adhering to the inside of the plug is removed or loosened by the scraper, *i*, and it is blown off with the water or steam. The plugs are ground steam-tight, and are kept in their places by the stuffing boxes.

SELBY'S PATENT SURFACE CONDENSERS.

MR. F. SELBY, of Surbiton, has recently patented a new arrangement of surface condensers, which he describes as follows :—

"I construct surface condensers of a series of chambers, cases, or tubes, each containing within it a coil, or coils, arranged in such a manner that the steam may pass inside the coils or coils, and a separate stream of water entering each chamber, case, or tube (in which a coil or coils are fixed) to condense the steam The coils may be made either of parallel or taper tubing and the coils themselves may be made either parallel or conical. They may be placed round each other by having each successive coil of larger diameter ; or they may be coiled together encircling each other, or in any other convenient manner.

"For small engines one coil and chamber will be sufficient, and although passing the steam inside the coils is believed most efficient and the water outside, yet this may be reversed if desired.

Fig. 1 of the annexed engravings is an elevation partly in section of one of my improved surface condensers composed of one coil fixed in a chamber or tube. Fig. 2 is a plan of the same. Fig. 3 is a sectional elevation of one of my condensers with two coils, one being round or encircling the other placed in the same chamber. Figs. 9 and 10 show in elevation and plan three coils arranged for being inserted in one chamber ; the number of coils may, however, be varied. Fig. 4 is a plan of Fig. 3. Fig. 5 shows an arrangement for connecting coils together. Fig. 6 is an end view. Fig. 7 an elevation, and Fig. 8 a plan showing an arrangement of a series of chambers or tubes, each containing one coil as shown at Fig. 1. The letters refer to similar parts in all the Figures. A A are the chambers or tubes in which the coils are enclosed. B is a bolt or tube for securing the ends D D of the chambers. C C are the coils. E F and G H are chests used when there is a series of chambers A as shewn at Figs. 6, 7, and 8. Although the chambers A are shewn cylindrical, they may be of any other form desired. They may also be employed as framing of engines.

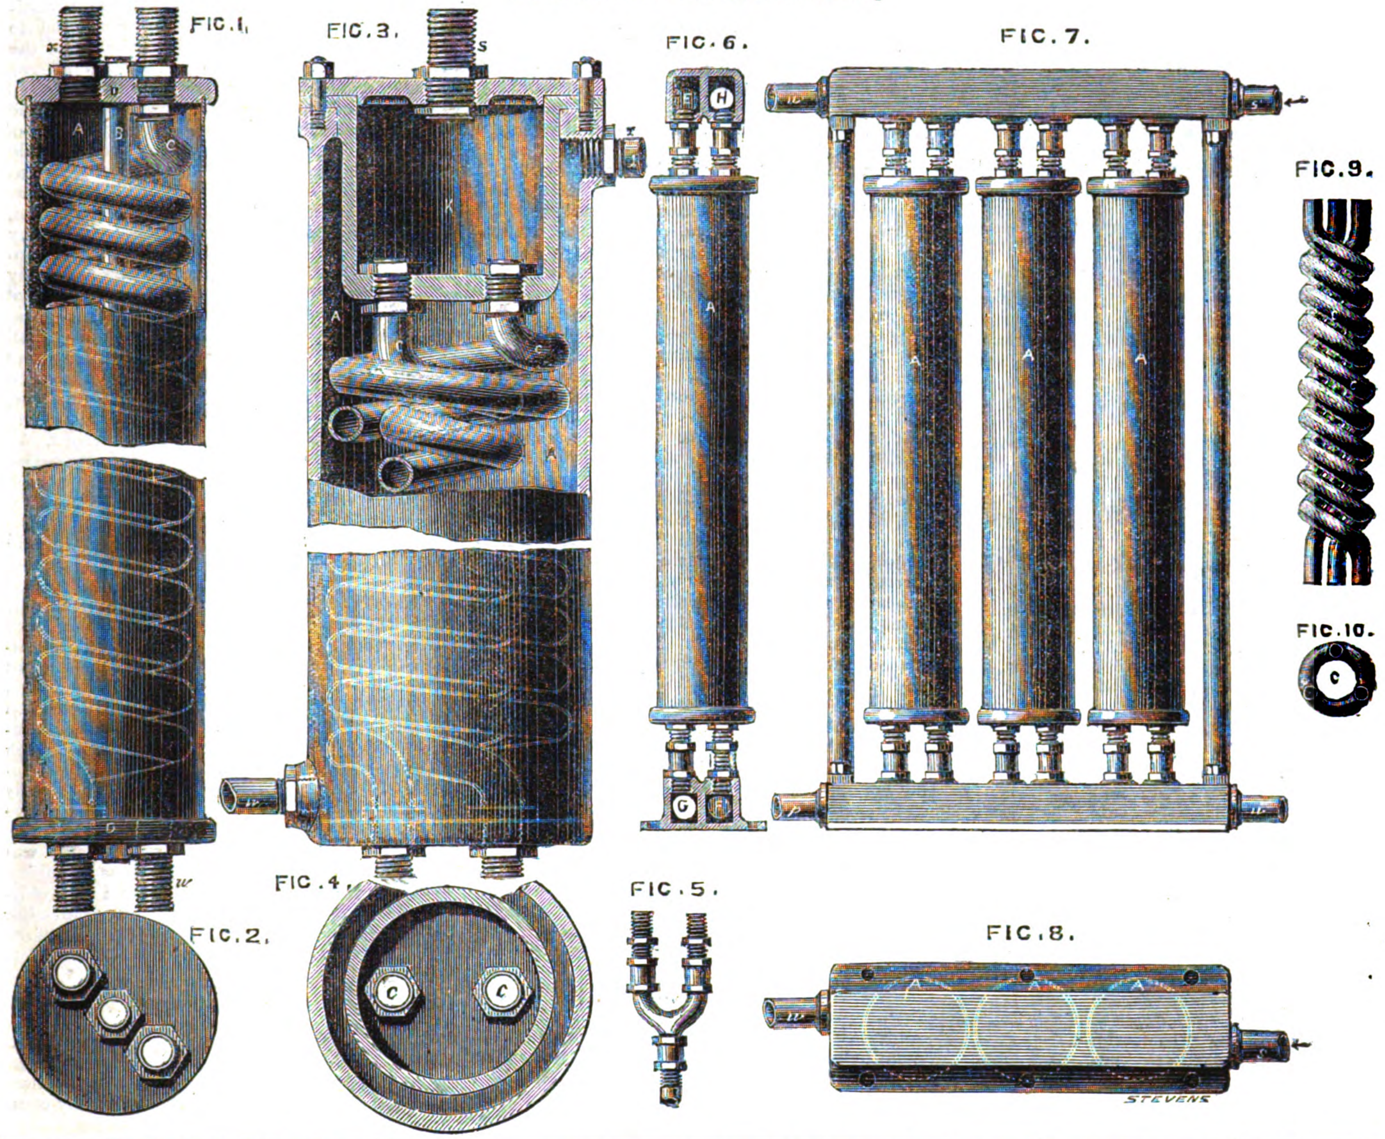
"The action of the condenser is as follows :—If for a small engine, only one chamber and one coil are necessary, as represented at Fig. 1, the exhaust steam from the engine may enter direct into the coil C, wherein it will be condensed, and the resulting water drawn out from the bottom end of the coil. The cooling water enters the chamber A through the pipe *w*, and overflows or is drawn or forced out through the pipe *x*, or *vice versa*.

"In Fig. 3 the exhaust steam enters the pipe *s*, into a chamber K, thence into coils C C, and when condensed flows or is drawn out from the bottom of the coils. The cooling water enters the chamber A as before described with reference to Fig. 1.

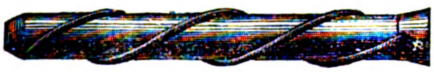
"When series of these chambers, containing a coil or coils, are used, as shown at Figs. 6, 7 and 8, the exhaust steam from the engine enters through the pipe *s* into the chamber or chest E, thence into the coil or coils, where it is condensed, and flows or is forced or drawn into the chest or chamber F, and issues through the pipe *p*. The cooling water enters through the pipe *w* and chest G into the chambers A A A, and is ultimately drawn, forced, or overflows into the chest H, passing out through the pipe *w*.

"Although only water has been mentioned in the description, as a means of cooling or condensing, yet any other medium may be employed if preferred. And the condensers may be used in refrigerating, distilling, and in all cases where air, steam, or gaseous fluids require condensation."

SELBY'S SURFACE CONDENSERS.



WIGZELL'S PATENT SHIP'S BOLT.



The accompanying engraving represents a bolt of a new construction for fastening ship's timbers, the invention of Mr. M. Wigzell, of Topsham, Devon. It consists of a circular formed bolt, or nail, having one or more worms, ribs, or projections, of such a form, and so placed in a spiral direction around its surface, as to cause the bolt, or nail, to revolve whilst being driven into timber after a hole has been made in the timber the size of its solid circular centre, and to hold into the timber with greater tenacity than the plain circular bolts now in use.

INSPECTION OF THE PNEUMATIC DESPATCH BY THE POSTMASTER GENERAL AND SIR ROWLAND HILL.

On Monday last Lord Stanley of Alderley, the Postmaster-General, and Sir Rowland Hill, the Secretary to the Post-office, officially inspected the working arrangements of the branch tube of the pneumatic despatch (which has been laid from the Euston-station to the north western post-office in Eversholt-street), previous to the transmission of the mails between the two places above mentioned, the Post-office authorities having conceded this privilege to the Pneumatic Despatch Company. The time appointed for the inspection was half-past 12 p.m., and on the arrival of the Postmaster-General and Sir Rowland Hill at the station, within the boundary of the Euston terminus, they were received by Sir Charles Rich, one of the directors; Mr. Margary, and Mr. Rammell, the secretary and engineer of the Pneumatic Despatch; Messrs. Blake and Stewart, of the London and North Western Railway, being among those present. The working arrangements were thoroughly explained by Mr. Rammell, the engineer, and trains of cars were rapidly propelled backwards and forwards through the tubes. The cars contained heavy weights, being principally loaded with stout planks, and on the signal being given by Wheatstone's admirable telegraph, they were despatched to the other end of the tube, with a pressure of about 4 ounces, in a few seconds over a minute, the average up the incline being about 1 minute 12 seconds, returning by vacuum in 1 minute 5 seconds. The mail bags, upwards of 120 per day, will be blown through the tube in 55 seconds to the post-office, Eversholt-street, the usual time occupied by the mail carts being at present about ten minutes. Two persons were conveyed, in the presence of the Post-office authorities, through the tube, and returned by vacuum without having experienced the slightest discomfort. Having fully examined the operation of blowing the cars from Euston, the visitors proceeded to the station at the other end of the tube. This is situated underground, beneath the roadway of a small turning leading from Eversholt-street, and is close by the side of the north western district post-office. Here the very interesting operation of sending the cars back to Euston was explained by Mr. Rammell, and two cars having been placed within about a foot of the open tube, a vacuum was created, and they were drawn with a rush into the tube, the small station reverberating with the sound of the receding train. This concluded the experiments of the day, and on leaving, both Lord Stanley and Sir Rowland Hill appeared favourably impressed with the entire working of the system—the Postmaster-General observing that it appeared from the experiments to be very satisfactory and very efficient. Previous to leaving the station at Euston, Lord Stanley descended with Mr. Rammell into the air chamber of the revolving disc, the motive power of which consists of a 15-horse power engine. The next step of the company will be to lay tubes connecting the markets of London with Camden goods station, with a tube to the General Post-office, and Pickford's depot in Gresham-street, and these operations will eventually tend to revolutionise the carrying system of the metropolis, and relieve the crowded state of our principal thoroughfares

THE INVENTORS' INSTITUTE.

Inaugurated 1st May, 1862.

Hon. Secretary.—R. Marsden Latham, Esq.
Bankers.—London and Westminster Bank.

At a Meeting of the Council of the above Institute, held on the 29th January, 1863, it was resolved that the following Report be received, adopted, and printed, and that copies of the same be respectfully presented to her Majesty's Commissioners, for enquiring into the working of the laws relating to patents for inventions.

R. Marsden Latham, Hon. Sec.

To the Council of the Inventors' Institute.

My Lords and Gentlemen,

As the Patent Law Committee of this Institute, appointed by you, "To obtain information respecting the patent laws, their practical operation and defects, and for the purpose of suggesting such alterations and improvements as may be found necessary," we beg to report that we have carefully considered, clause by clause, the following Acts of Parliament, relating to letters patent for inventions, viz: 21 James I. cap. 3; 5 and 6 William IV. cap. 62; 5 and 6 William IV. cap. 83; 2 and 3 Victoria, cap. 67; 7 and 8 Victoria, cap. 69; 15 and 16 Victoria, cap. 83 (the Patent Law Amendment Act of 1852); 16 Victoria, cap. 5; 16 and 17 Victoria, cap. 115; and 22 Victoria cap. 13. We have discussed the principles of the present system in their general bearings, and the alterations and improvements we would now recommend, for the most part, may be classified under the four following heads:—

I. The mode of granting patents.
II. The duration of patent rights.
III. The cost of patents.
IV. Legal procedure generally as regards patent right, and particularly as regards infringements of patents—the question of scientific evidence, and the desirability of establishing a patent law tribunal or court for the trial of patent causes.

I.—As to the Granting of Patents.

Practical benefit, we believe, would result both to inventors and to the public from the establishment of an official scientific body of competent and experienced persons acting in conjunction with the Commissioners of Patents for Inventions, to investigate the question of novelty on all applications for patents, and whose duty should be to inform the applicants if their alleged inventions be new or old, leaving each applicant to determine for himself whether, at his own risk, he will take the patent out or not.

But as regards the utility and importance of inventions, it might be productive of great injury to inventors to empower any body of men to consider either of those points. Questions of utility and importance can be safely determined by time and actual trial only, and it has been well observed, that "what may appear simple and trifling in one age, often becomes a great invention in another."

Many important and valuable inventions would undoubtedly have been lost to the public, had the efforts of inventors been arrested in their progress by the condemnatory, but erroneous, opinions by which the inventions were at first assailed—opinions for the most part pronounced by the very men esteemed the most competent to judge. Mankind are always slow to receive new truths, and the history of invention and discovery affords many notable instances of great and valuable inventions having been received, not merely by the ignorant, or the world generally, but by the learned and the great men of science, with derision and mistrust. These views receive almost daily illustration; and facts, such as the incredulity and opposition which retarded the first introduction of gas-lighting, railways, and locomotives—Franklin's discoveries with regard to electricity—Watt's steam-engine—the transmission of messages by means of electricity—the propulsion of vessels by steam, and a host of other inventions, conclusively demonstrate the dangerous fallibility of human judgment when endeavouring to estimate the true character or importance of things previously unknown or little understood.

We are of opinion, that no power to refuse applications for letters patent beyond what is now practically exercised, should be conceded or allowed. The power of refusal is entrusted to official investigators, in a few countries abroad, but our experience of its operation in those countries has been generally unsatisfactory, and we view the system with feelings of unequivocal mistrust. The system does not prevail, moreover, in France, Belgium, or in other nations, whose policy respecting invention is more advanced than that of our own country.

Few inventions can be brought into general use in a less period than three or four years; indeed some inventions are so far in advance of the age, that a life-toil of labour is scarcely sufficient to secure, not merely their adoption, but even the recognition of the scientific truths they involve. In a majority of cases of this kind, official preliminary investigation, followed by any consequent stoppage of patents, would obviously be premature, sufficient time not having been allowed for the proper practical development of the invention, and adverse, erroneous decisions in such cases would inflict, not only serious injury upon the public, but would occasion the ruin of many meritorious inventors, whose means had all been expended in bringing their inventions to perfection.

We would further observe that, in considering the question of novelty, it frequently happens that the only points of difference between a subsequent and a prior invention, are distinctions extremely delicate and minute, which, though seemingly trifling and frivolous, yet constitute, in practice and effect, the all important difference between failure and success. Numerous additional instances can readily be furnished, showing how highly dangerous and impolitic it would be to make an adverse decision, on the part of any preliminary investigators, the ground for refusing a grant of letters patent; but, enough has been stated on the subject for the purposes of this report. We will further remark, however, that no immediate appeal would remove the difficulty in question, it being beyond doubt that no body of men, whether legal, scientific, or otherwise, are equal to the task of pronouncing authoritative and final judgment on the inutility or non importance of all the new and multifarious inventions which are continually being produced by the ablest and most ingenious minds of a country so eminent for its mechanics, engineers, manufacturers, and men of science, as our own.

Still, after mature consideration, we are inclined to believe that many advantages would arise from a well conducted preliminary investigation, if its direct effect were restricted to placing officially on record the opinions of the investigators, touching the novelty of alleged inventions. We, therefore, recommend that a full description of the invention should be submitted to the investigators, previous to the sealing of the patent, whereupon the investigators should at once institute a search; and if they arrive at the conclusion that the alleged invention, either altogether, or in part, is not new, their opinion, with suggestions for any rectification which may seem desirable, should be transmitted to the applicant. If, then, the applicant refuses to comply with the suggestions made, and, moreover, cannot satisfy the investigators that they have misapprehended the subject, for which opportunity shall be given him, the opinions of the investigators should, with the sanction of the law officer, be placed on record; the applicant, however, having the right reserved to move at any future period for the cancelling of the record. An investigation so conducted would in practice occasion the withdrawal of applications for such patents as would not be sustainable at law; for few inventors, on it being distinctly shown to them, that their inventions are not new, would be foolish enough to proceed further in obtaining an obviously bad patent, and thus incur needless additional expense. The public, also, would pay little heed to a patent with a condemnatory official record upon it; and supposing the investigators had not distinctly erred in their judgment any patent of that character, if brought into a court of law, would certainly bring disaster upon the patentee. On the other hand, the investigators feeling that their decisions, even though adverse, were not irremediable, would not be influenced by the doubts which must necessarily arise in their minds when endeavouring to arrive at decisions upon new inventions. The value moreover, of those patents whose novelty was undisputed, would be greatly increased; capital would the more readily be embarked in developing inventions thus approved, and the inventor would be encouraged to prosecute his efforts with that energy and zeal which alone lead to success.

II.—The Duration of Patent Rights.

We strongly recommend that the attention of the Legislature should be called to the comparatively short time for which patents for inventions are granted, and to the injustice thereby occasioned to inventors.

The writer of a book, however frivolous or useless the book may be, can obtain, at the expense of a few shillings, a copyright for 42 years certain; and, regarding all intellectual rights as equal, why should the man who stamps his thoughts upon matter be less liberally dealt with than the owner of a copyright?

A 14 years' patent right is surely a somewhat niggardly encouragement to inventors, since, during so short a period, few inventors are enabled to obtain anything like fair remuneration for the labour and skill required for practically developing and perfecting new inventions. A large outlay of capital, moreover, is usually necessary to bring an invention into general public use, but such an outlay is seldom justifiable, seeing that at the expiration of so short a time any person can step in and reap the benefit of whatever demand the expenditure of capital may have created. Hence, the labours of the poorer class of inventors are often fruitless, and many inventions, which otherwise would have been productive of much good, are never brought before the public. We are aware that some inventions come into general use more speedily than others, but, even in such cases, the term of patent right should not be less than twenty-one years.

We submit that the following resolutions, with reference to the granting of patents and the duration of patent rights, should be carried into practical effect:—

"1. That it is desirable to recommend the official appointment of a board of investigators, before whom all applications for letters patent shall be presented for consideration.

“ 2. That no report or opinion of the proposed official investigators shall prevent any applicant from obtaining a patent when such applicant, nevertheless, persists in applying for the same.

“ 3. That the official investigation shall take place under the control of her Majesty's law officer, not on application for provisional protection, but after notice to proceed.

“ 4. That all patents should be granted for a term of not less than 21 years.

“ 5. That no description of an invention shall be deemed a publication unless such description be found in a place fairly accessible to the public, or unless such description be written or printed in the English language.

“ 6. That the application for a patent must be made as now by the actual inventor, if alive, or by a person duly authorized by him in writing, but if the inventor be dead, the application may be made by his executors or administrators, or by a person duly authorised by them.

“ 7. That an inventor shall be permitted, on due notice given before the expiration of six months, provisional protection, to have his provisional specification returned to him, and it shall not be published.

“ 8. That it is very desirable that all grants of disclaimers and memoranda of alteration should be subject to such regulations as will secure greater consistency of practice.

“ 9. That with regard to the confirmation of letters patent, such an amendment should be enacted that the inventor or introducer of an invention may more readily, and with greater certainty, have his patent confirmed, notwithstanding a limited prior use.

“ 10. That there should be an amendment of the power of extending the term of letters patent.

“11. That it would be desirable, that any person dissatisfied, either with the allowance or refusal as to any disclaimer or memoranda of alteration, should be permitted to appeal to the Lord Chancellor or Privy Council.

“12. That so much of clauses 12 and 13 of the Patent Law Amendment Act of 1852 as refers to the investigation of rival claims should be expunged, and that in lieu thereof the notice should be given to the board of examiners prior to their investigation, who shall report to the law officer referred to in clause 13.

“13. That a patent should embrace all her Majesty's dominions, and such arrangements as would obtain the concurrence of the respective Colonial Governments would be most important.

“ 14. That it is desirable that clause 19 of the Patent Law Amendment Act of 1852 should be expunged.

“ 15. That an acknowldgement or receipt should be given by the Patent Office officials immediately on the recording of documents, or on the payment of fees.”

III.—As to the Cost of Patents.

We submit that the cost of patents should not exceed what is absolutely necessary to defray office expenses.

The high cost of patents renders it quite hopeless for most persons with limited means to seek protection for their inventions, and numerous useful and valuable ideas are, consequently, lost to the public. Many inventors, knowing that they cannot afford the charges exacted, and seeing no fair prospect of being able to pay for a patent, will not allow themselves to be led into a new inquiry, and are thus deterred from carrying on the experiments necessary to practically and beneficially develope their new ideas. Perfected inventions also of great value, which, if publicly made known, would give employment to a great number of hands, are notoriously kept secret, and withheld from public use, owing to the expense of taking out patents; such inventions are all doubly lost, since, if known to the public, they would become the subject of researches which might lead to other very important and beneficial results.

The high cost of patents, moreover, frequently obliges inventors of limited means, when seeking the assistance of capital, to enter into disadvantageous arrangements, and thus many hardships and great injustice are occasioned. We may here observe, also, that the 3rd and 7th year's payments of £50 and £100 fall very heavy on many deserving inventors, who, from sheer inability to pay, are compelled to relinquish valuable patents when just on the eve of realising their hopes of advantage.

Even with regard to the so-called “ frivolous ” and “ useless ” inventions, the present prohibitory charges are most impolitic and injurious in their effects. A “ frivolous ” invention, so-called, may nevertheless, from the extent of the demand, give employment to many idle hands, it may require for its construction many taxable materials, and form an article of export, so as to become profitable to the community; whilst a “ useless ” invention, so-called, will not unfrequently indicate to other inventors, who may succeed better, a want to be supplied, and so lead to the speedy accomplishment of what is desired. An invention, however useless it may seem, may be suggestive of and give rise to other inventions of undoubted practical utility, and it often happens that the first inventor, though stumbling at every step, and himself unable to achieve success, yet opens up a broad path for other inventors who come after him.

The following abstract of receipts and disbursements has been prepared by a member of this committee from the official reports extending from October, 1852, to December, 1861, published by the Commissioners of Patents for Inventions :—

RECEIPTS AND EXPENDITURE OF PATENT OFFICE 9¼ YEARS, OCT. 1852 TO DEC. 1861.

	1852-3.	1854.	1855.	1856.	1857.	1858.	1859.	1860.	1861.	Totals.

Paid to Revenue account	,,	,,	35,100	16,685	15,275	15,350	17,725	20,195	18,485	138,815

In the foregoing abstract the odd shillings and pence have been omitted for convenience, and the amount is added in one sum in the following statement :—

Total receipts		£772,778
Payments	£502,935	
Add for difference of shillings & pence .	000,006 ——	502,941
		269,837
Deduct revenue fees		138,815
Surplus		£131,022

It appears, therefore, that after defraying all expences from October, 1852, to December, 1861, there remained a balance of £269,837, of which sum, however, £138,815 was paid as revenue fees into the governmental taxation account, leaving still unappropriated a surplus of £131,022. But why a sum of £138,815, levied from inventors in the obtaining of their patents for new inventions, should have been paid into the governmental taxation account, would seem to require explanation, there being no principle of equity or even of sound public policy, on which so objectionable a tax can be defended.

As regards the still unappropriated surplus of £131,022, which will probably be increased by the year 1862, to £170,000, we submit that in common fairness this and any future surplus should be directly applied to some purpose in connection with the encouragement of inventors and the advancement of practical science.

It also appears, from the foregoing abstract, that whilst the annual receipts from inventors now exceed £100,000, the actual expenses of the Government Patent Office fall below £47,000 per annum, whence it is obvious that a great reduction in the cost of patents can be made without injury, even to existing interests.

In the apportionment of the proposed reduced charge, we recommend that the charge for Provisional Protection should be made as small as possible. This unquestionably would be a great boon to the poorer class of inventors, who then could secure their inventions, and would thereby be enabled to treat with capitalists on more equal terms than at present for the means of bringing their inventions into public use.

With reference to the cost of patents we would further observe, that the question, affecting as it does the whole progress of invention in this country, is one of most serious importance, and requires a thorough and liberal revision on the part of the Legislature. Practical and scientific men, conversant with the state of manufactures abroad, are generally agreed that it is only by dint of great exertion, under the most favourable circumstances, that the supremacy of this country in the manufacturing and chemical arts can be maintained. The comparative cheapness of food abroad, the lightness of taxation, and the liberal encouragement afforded to science and its cultivators by foreign Governments, all materially contribute to counterbalance the natural advantages we possess; but *the chief causes which check invention in this country, impede the progress of the industrial arts, and give the advantage to our foreign competitors, are the high cost of obtaining patents for inventions, and the very doubtful protection which our laws extend to them when obtained*, and we would urge upon our Government the paramount necessity which now exists for a greater and more liberal encouragement to invention than has hitherto been practised. We do so in the confident belief that, were the difficulties we have adverted to removed, it might reasonably be hoped that every new idea and every effort of invention and discovery would then be brought before the public and elaborated for the use of man.

The following are the resolutions we have passed with reference to the cost of patents:—

"16. That it is not politic, or right to subject inventors to any other expenses than such as are absolutely necessary to defray the official expenses incurred in securing to them the protection of their inventions.

"17. That it is only reasonable and just that the existing surplus of funds, levied from the inventors since 1851, be directly applied to some public purpose, in connection with the encouragement of inventors and the progress of practical science.

"18. That from the experience obtained by the operation of the new patent law, during the last ten years, it is manifest that the present charges for patents are very much too high, and we consider that the total expense attending the obtaining letters patent should not exceed £25. That this sum should be divided into five sums, of 50s. each, and a sum of £12 10s.—the five sums of 50s. to be payable in lieu of the present five £5 payments, and the sum of £12 10s. to be payable at the end of the 5th year, or in such other manner as the Commissioners of Patents may deem advisable; but the committee recommend that the first payment should be made as small as possible.

"19. That all further payments on existing patents should be reduced to this proposed scale.

"20. That as soon as the time at which the sums should be paid, and the final specification deposited, has arrived, the patentee, if he has not complied with either of these formalities, shall, within 24 hours, be served, by one of the clerks of the Patent Office, with a notice in writing, or forwarded through the Post-office at the address mentioned by the patentee in his petitition or declaration, stating that the time for the accomplishment of the formality in question has elapsed, and that, if within 28 days from the date of the said notice in writing, he has omitted or otherwise failed to comply with the formality in question, his application shall be null and void, or his patent, if he has one, cancelled; whereupon, if within the 28 days, the patentee, or any person acting for him, fulfil the stipulations of the act, and pay to the said clerk an extra fee of 20s., it shall be lawful for the clerk of patents to comply with and fulfil the formalities as if the application had been made at the proper time."

IV. Legal Procedure generally as regards Patent Right, and particularly as regards Infringements of Patents—the Question of Scientific Evidence and the Desirability of Establishing a Patent Law Tribunal or Court for the Trial of Patent Causes.

We are still engaged in considering these very important points, and in obtaining information thereon. A second report will be issued in the course of a few weeks, in which all our views and resolutions on the points in question will be fully set forth.

The following resolutions have been already arrived at:—

"21. That in clause 35 of the Patent Law Amendment Act of 1852, after the words 'the assignment of any letters patent, or of any share or interest therein, any license under letters patent,' the following words be inserted, 'provided the instrument bears under the signature of the patentee the words *to be duly registered*.'

"22. That the following words be added at the end of clause 35 of the Patent Law Amendment Act, 1852, 'provided always, that the parties to any assignment or license shall be estopped from impeaching or impugning the validity of such patent so assigned or licensed.'

"23. That when any objection to the validity of any patent which is, or has been, before a court of law can be removed by the entry of a disclaimer or memorandum of alteration, such court may order the entry of a disclaimer or memorandum of alteration."

We cannot conclude this report without expressing our thanks to Admiral Sir Edward Belcher, Mr. Robert Richardson, Mr. J. J. Aston, Dr. Normandy, Mr. Richard Roberts, Mr. Hume Williams, Dr. Collyer, Mr. Campin, Mr. Fuller, Mr. Jennings, and Mr. Varley, for their unceasing labours as members of this committee, and for the assistance which their great experience has afforded us whilst considering the very difficult questions which it has been our pleasure to discuss.

CROLL'S TREATMENT OF AMMONIACAL LIQUOR OF GAS WORKS.

Mr. A. A. Croll, of Coleman-street, proposes to avoid the inconvenience and annoyance arising from the treatment of ammoniacal liquor of gas-works in the following manner:—

"Steam from a suitable boiler is conveyed into ammoniacal liquor contained in a suitable closed chamber, and the combined vapour and steam resulting are conveyed from the upper part of this chamber into other ammoniacal liquor contained in another closed chamber placed somewhat higher than the preceding, in order that as the ammoniacal liquor in the previous chamber becomes spent it may be supplied from the second, and if desired other number of such ammoniacal chambers may be employed. From the last ammoniacal chamber the vapour resulting, combined with particles of steam, is conveyed into a closed compartment or chamber of a vessel containing acid adapted to the salt of ammonia desired to be obtained. Thus, supposing the salt desired is sulphate of ammonia, then this last chamber will contain sulphuric acid, and it is at its upper part divided into two compartments, one open at the top, the other closed by a cover, and a partition dipping below the surface of the acid liquid therein and below the mouth of the pipe conveying the vapour and steam thereto from the last ammoniacal chamber. Any vapour arising from the closed compartment of this vessel is conveyed into similar acid in another closed chamber used as a reservoir. From the upper part of this last closed chamber the sulphuretted hydrogen liberated is conveyed to the furnace supplying a vitriol chamber.

"By these means economy and the avoidance or great mitigation of the inconvenience and annoyance arising from the treatment of the ammoniacal liquor of gas-works is secured."

OUR DOCKYARD EXPENDITURE.

A blue book has been recently issued containing balance sheets showing the cost of manufacturing articles in the workshops of the several dockyards and steam factories for the year 1860-61. The dockyards and steam factories from which accounts are presented are Deptford, Woolwich, Chatham, Sheerness, Portsmouth, Devonport, Pembroke. Taking the first table, under the head of mast houses, we find that in the year 1860-61, the total debit for these was £110,042 15s. 9¼d. The highest was Portsmouth, £44,051 8s. 4d.; the lowest, Deptford, £178 7s. 3d. Devonport figures for £20,111 10s. 6½d. In boathouses the expenditure is not very large, commencing with £2,239 3s. 6d. at Woolwich, and ranging to £7,172 4s. 3d. at Portsmouth, Devonport coming in for £5,351 19s. 3d. In capstan houses Chatham stands for the highest, £3,782 16s. 8¾d.; Devonport comes next with £3,084 18s. 7d.; Pembroke is the lowest, £521 7s. 5d. In joiners' shops Devonport stands first, £3,976 4s. 7½d.; Deptford is the lowest, £897 4s. 5d. From two of the dockyards, Deptford and Pembroke, no separate accounts were received from the plumbers' shops, and in none of the establishments from which these were sent was the amount large. At Chatham it was £3,976 15s. 11¾d.; at Portsmouth, £53 6s. 11d. The total debit for wheelwrights' shops in all the dockyards was 1,827 5s. 10½d. Four of the dockyards spent £17,081 0s. 10d. in their millwrights' shops; three, Deptford, Woolwich, and Pembroke, send no return. This is the same in the roperies' department; but in Chatham, Sheerness, Portsmouth, and Devonport, £371,671 5s. 0½d. was expended under this head. As in the joiners, here also Devonport takes the lead—£169,281 3s. 0¾d. Chatham stands for about £27,000 less; Portsmouth, £58,648 18s. 10d.; Sheerness about one-fiftieth part of that sum. An extensive business has been done in sail lofts: Portsmouth, £17,260 16s. 9d.; Devonport about £1,100 less; Pembroke the lowest, £66 14s. 2d. For colour lofts the total debit was £2,299 14s. 2¾d. Devonport was the highest; Sheerness the lowest. Sheerness stands first in the rigging-house department, Woolwich the last, the figures varying from £10,822 19s. 5d. to £16,131 5s. 10d. In the lead, paint, metal, and cement mills, the items are unimportant. Coming, then, to blacksmiths' shops, we find returns from only Portsmouth and Devonport; the former £27,689 10s. 4d.; the latter £736 12s. 11½d. The expenditure in the treenail houses was small; Pembroke was the highest; Deptford the lowest; whilst from Portsmouth no account was received. Oarmakers' shops show a total of £6,243 9s. 6½d.; from Deptford, Woolwich, Sheerness, and Pembroke, no returns were sent. For caulkers and pitch heaters the expenditure was £11,379 12s. 4d.; Portsmouth, £5,959 4s. 6d.; Devonport, £2,647 14s. 2d. Passing over the turners' shops, which do not show for much, next is presented "locksmiths', tinmen's, and braziers' shops;" these are somewhat over £2,000, and none of the items are likely to be challenged by the hon. member for Lambeth. The charge for foundries is scarcely what might have been expected—£5,682 4s. 9¾d.; from Deptford, Woolwich, Sheerness, and Portsmouth, there are no returns. For painting in the several dockyards, £5,170 3s. 7¾d. The only condenser's shop is at Portsmouth, where £15,831, 18s. 8d. was expended; here, also, is the only pump house, which goes down for £840 10s. 0¾d. The only dockyard from which a fire-engine account was received was Devonport, where the expenditure was £145 6s. 4d. "Smitheries" is a heavy item, no less than £211,606 18s. 5¼d. being put down for them. Of this, £55,000 was spent at Portsmouth; £49,000 in the north and south smitheries of Devonport; £32,000 at Chatham; £27,000 at Woolwich; £18,000 at Sheerness; £14,000 at Deptford; and £13,000 at Pembroke. In steam-hammer shops, Portsmouth stands for £13,302 16s. 1d.; Devonport, £11,089 12s. 7d.; Deptford, £3,102 9s. 7d. At Portsmouth nearly £7,000 was expended in the iron-foundries, and at Keyham £4,481 14s. 6d. Brass-foundries—Portsmouth, £45,522 12s. 7d.: Keyham, £13,474 12s. 4d. Copper-smiths' shops—Portsmouth, £4,851 19s. 10d.; Keyham, £4,234 17s. Engine smitheries—Portsmouth, £5,850 15s. 4d.; Keyham, £5,659 10s. 3d. Boiler smitheries—Keyham, £5,394 9s. 10d.; Portsmouth, £5,148 8s. 4d. The total expenditure in the dockyards for the year 1860-61 was £1,362,505 3s. 8d.; and in addition to this, under the head of shops in the steam factories, there is £144,881 3s. 4d.

TELEGRAPHIC INTELLIGENCE.

An Electric Telegraph Across the Mersey.—In consequence of the frequent accidents to the submarine cable arising through the fouling by ships' anchors, the cable has been taken up, and at present messengers perform the communications. It is, however, intended to erect on each side of the river two iron pillars of about 240 feet in height, and on these to extend a strong steel wire, to which will be fastened the telegraph wires. The distance across the Mersey, where it is proposed to erect the pillars, is about 1,300 yards. In connection with the proposed alteration, which seems a very feasible one, we understand that there will be a submarine cable laid between the different lightships, outside the port and the shore, which will be of immense service to the mercantile community, as it will accelerate the reporting of vessels off the port, and, in cases of storm, the position of vessels in distress, &c.

Telegraph to India.—The second ordinary general meeting of the proprietors of the Telegraph to India Company was held this week; Sir

Macdonald Stephenson presiding. The report stated that an arrangement for working the Alexandria and Suez line, which it was hoped would enable the shareholders to realise a dividend during the next four years of from 4 to 5 per cent., had been entered into with Messrs. Glass, Elliot, and Co. To complete the communication to Beyrout, Iscanderoon, or Aleppo, the sanction of the Viceroy of Egypt for the construction of a line to El Arisch had been obtained. The board was not competent to construct the line to Beyrout, and it was therefore suggested that this branch should be registered under the act as a new and co-operative company, the shareholders in the parent company to be entitled to their rateable proportion of shares. The report was adopted, and afterwards the following resolution was agreed to:—"That this meeting approves the proposed arrangement for forming a company with a paid up capital of £50,000, for the purpose of making a line of telegraph to connect the company's line with the Constantinople and Persia Gulf line to India (the shares in which are to be offered to the shareholders in this company), in accordance with the proposals of Messrs. Glass, Elliot, and Co."

Universal Private Telegraph Company.—The half-yearly meeting of the Universal Private Telegraph Company was held on Tuesday, at the offices, 448, West Strand; Mr. Alderman Salomons in the chair. The company had now established their system in the metropolis, and a considerable area was traversed by its lines. In Glasgow lines had been established with marked success, extending as far as Greenock, Paisley, Barhead, Busby, Campsie, and the Vale of the Leven, between 20 and 30 miles distant. Operations were also proposed in Dundee and Edinburgh. The company had recently commenced the development of an extended system in and around Manchester, and the whole of the manufacturing districts, where the advantages of private communication were highly appreciated. In Liverpool, Birmingham, Newcastle, and on the banks of the Tyne, extensive works were also proposed. The success attending the operations so far, and the estimation in which the system was held by those adopting it, were such that there was no doubt that a large and increasing business would yearly advance the commercial prospects of the company. The difficulties of introducing long circuits had been overcome, and the future extension of the lines might be regarded as based upon the most perfect system at present available. The financial result of the company's operations to the end of August last showed a net revenue and expenditure sufficient to declare a dividend of five per cent.

PHOTOGENIC GAS.

According to the newspapers, we find that on Saturday last some experiments were made at the offices, in 95, Bishopsgate-street, of Mr. Mongruel's patent cold vapour regenerator, an invention for the production of a brilliant and economic light from ordinary gas or atmospheric air. The Photogenic Light was invented by M. Mongruel in the beginning of 1862, and it is stated to be already adopted in several of the large towns of France, and in many of the largest cafés and establishments of Paris. It was, moreover, reported on by a commission appointed for the purpose by the Société des Sciences Industrielles, Arts, et Belles Lettres of Paris in October last, and the results of their inquiry are thus stated:—1. That there is a guaranteed reduction of 50 per cent. at least in the consumption of gas to give an equal light. 2. Or, with an equal consumption, there is a luminous intensity double or treble that of the primitive light. 3. Whiteness, regularity, and tranquility of the flame, which, softer to the sight, fatigues less in reading or working. 4. Purification of the gas from its pitchy or napthaline atoms, from its ammoniacal vapours, and the sulphurous acids it carries with it from the factory. 5. Consequently, preservation of paintings, varnish, gilding, and delicate colours, which in establishments lighted by gas are so promptly attacked by these mordant agents. 6. Complete absence of odour and smoke. 7. Lastly, real advantages for the consumer, to whom the inventor guarantees, all expenses paid, 25 per cent. of positive economy on his habitual expenses for gas lighting. The experiments of Saturday last were conducted and explained by Mr. Thomas in the most satisfactory manner. The first experiment was made upon the ordinary gas in use in that part of the city. This gas, when passed through the generator containing the liquid used by M. Mongruel, acquired a vastly increased illuminating power, while the flame of the jets was purer, softer, and steadier. But though the light was more intense the expenditure of gas was less, for, tested by a gas-meter and chronometer, the consumption given was in the proportion of 6 to 10, which is equivalent to a saving of 40 per cent. The next and the most interesting experiment was made upon atmospheric air, which, when passed through the apparatus and liquid, burned with a beautiful clear and steady light. Some idea of the brilliancy of this light may be obtained when it is stated that as measured by a photometer one jet of the ignited air gave more illuminating power than four jets of ordinary gas of equal size. As far, therefore, as the experiments of Saturday were concerned, nothing could be more complete and satisfactory. The capacity of being able to obtain light from the atmosphere must prove of immense advantage in those localities where there are not the means of getting it by the ordinary method hitherto employed; and it is stated that M. Mongruel has had more demands than he can attend to from private individuals for the application of his invention in their mansions. Ingenious inventors have been, and are still, occupying themselves with the carburation of gas, since it has long been known that by dissolving carburetted hydrogen vapours in hydrogen gas, the latter requires a treble or quadruple illuminating power. What, however, was wanted, and M. Mongruel appears to have succeeded in inventing, is an apparatus which will produce a constant vapour, always equally rich in carbon, so that the light is at all times the same. In all other apparatus used for the purpose, the generation of the vapours being effected on the mass of the liquid contained therein, the most volatile parts of the liquid naturally first escape, thus impoverishing the remainder, which daily gives less and less light, until the light disappears altogether, while a considerable quantity of the liquid is still left in the apparatus. In M. Mongruel's generator, on the contrary, the mass of the liquid is enclosed hermetically in an upper chamber, whence it descends by a small tube, to form a thin sheet on the bottom of the lower chamber, wherein its vaporisation is effected, and is supplied, drop by drop, only as what has preceded it is consumed.

SCOTTISH SHIPBUILDERS' ASSOCIATION.

December 1, 1862.

James Rodger, Esq., Vice-President, in the Chair.

(Continued from page 60.)

Remarks on the Build and Equipment of Passenger Steam Vessels. By Mr. George Barber, Shipwright Surveyor to the Board of Trade.

At your last meeting a long and interesting discussion took place upon FORECASTLES, and it seemed to be generally admitted that, as far as space is concerned, forecastles are not what they should be. Now, I find that the sailors do not complain so much about want of room; they will put up with the inconvenience of a small place, and with the discomfort of an insufficiently lighted and badly ventilated forecastle, provided it is dry and tight; and, from what I have myself seen, I know that they have often just cause of complaint about leakage. If it be true that water finds its way into the topgallant forecastles of large vessels, through the butts of the deck planks, which yield when the vessel pitches, it is a proof that such forecastles would be better if additionally strengthened in a longitudinal direction; but I believe that a great deal of the leakage complained of might be prevented by adopting the simple method of making a square butt, say of two inches in length, to the fore-end of the foremost deck planks. I know that this *is* done by many builders; they joggle the ends of the planks into an inner waterway, or into each other, and thereby get good wood for caulking and fastening; but many builders do *not* do it; they allow the men to dub the ends of the planks away to a sharp point, and then fit them against the main waterway or covering-board. The saving of time is the object; but it is a slovenly practice, and I defy those who permit it to get either good caulking or good fastening at the ends of the planks, or to prevent the sailors being subjected to the annoyance and discomfort of a leaky forecastle.

I have, on several occasions, been asked to give my opinion upon the rudders of new vessels—whether they are of the proper form and sufficient size? It appears to me that the most efficient form and area of rudder can only be determined by experiment; but if any member here has studied the subject, and is aware of a rule that will admit of general application, I hope he will put us in possession of his information.

I should like to see the practice of fitting rudder-pendants more generally adopted. Since I have been at this port some three or more cases of vessels having twisted or broken their rudder-stocks have come under my observation, and I cannot see why every coasting, as well as foreign-going steamer, should not have the pendants fixed round the stern; nor why, during the winter months especially, the precaution of having them shackled to the back of the rudder should not be taken.

I find that Mr. Hall, in his most valuable paper, read to you on the 3rd March last, directed your attention to masts, rigging, steering-gear, and windlasses. An excellent paper "On Sail-making" has also been read to you; and I will therefore pass on to the subject of Equipments.

I do not think that anything need be said about ANCHORS, as I never hear any complaints made of their inefficiency. The common anchor, the anchors of Brown, Lennox, and Co., and the patent anchors of Trotman, Rodger, and Betteley and Millar, have each their advocates; and as they all do their work well, it is not at all necessary to enter into the question of their respective merits.

It always occurs to me when I see a vessel launched at any of your yards, and "brought up" by her CHAIN CABLES, how necessary it is that before the cables are stowed away in the lockers they should be, I will not say tested—because you will reply that by the very act of launching they have been subjected to a more severe strain than will ever be brought on them again—but that every link should be thoroughly and minutely examined. I have, on more than one occasion, seen one of the cables snapped asunder, and the vessel "brought-up" by the other. A new link is put into the broken length, and the cables are hauled on board and stowed away; but who knows whether the cable which did not break may not have been permanently injured, and may not give way at a time when it will be most needed? I certainly think that after cables have been subjected to such a sudden and severe strain as is brought upon them in launching, every link should be most carefully examined; and I may here state that it has often been to me a matter of surprise that, although in my district there are thirty building yards, from which more than seventy vessels are launched every year, there is not in the whole district—what I am sure would be found a great advantage to this port alone—a public chain-testing machine.

I have never yet been able to get a satisfactory reply to the question, "How ought the end of the chain cable to be secured in the locker?" Some men of experience contend that the end should be secured by a rope-lashing to an eye-bolt or beam at the upper part of the locker, so that, if it should be necessary, the lashing could be immediately cut with an axe; while others, equally experienced, maintain that the proper way is to secure the end to a strong shackle riveted on the keelson or strengthened floor plate.

Then, as to HAWSE-PIPES. How very few vessels have their hawse-pipes fitted in a proper direction! Instead of stiveing downwards, in the direction of the cable when the ship is at anchor, they are more often fitted, for appearance sake, in such a direction that the cable is subjected to almost as severe a nip as if it were led over the edge of an anvil. I should like to see all large foreign-going vessels fitted with two hawse-pipes on each bow, so that, in a case of emergency, there would be no difficulty in getting out a third anchor.

Some trials of patent PUMPS have recently been made at Woolwich, and very excellent results have been obtained; but for steam-ships, which generally are well provided with the means of pumping out the holds, by either the main cr donkey engine, or by the pumps attached to and worked by the steam winches, I think that hand-pumps of the description fitted to the Clyde-built vessels are sufficient. The only objection that I have to them in coasting steamers is that, as they are flush with the deck, they are very liable to be covered over by deck cargo; and, on this account, I prefer those pumps which have a cast-iron chamber, standing 18 or 21 inches above the deck, and which, at both the up and down stroke, discharge a large volume of water through a nozzle cast on the side of the chamber. If in vessels which are divided into several compartments, and which have a corresponding number of pumps, each standard were to be made to fit into any socket, each brake into any standard, and each spear and box into any brake and chamber, there would not then be that confusion, trouble, and loss of time, in rigging the pumps which I have often seen, even though each set of gear may have had, when it was new, a distinguishing number or mark; and although—to use the argument which I hear so often repeated—"the pumps may never be wanted," it would be a good thing if masters would make it a rule to have the pumps rigged at stated periods, so that they may be able to see for themselves whether or not the working parts and leathers are in an efficient condition. When leaden roses are used, they should not be placed directly upon the skin of the ship, as I have often found the plates underneath, and in the wake of them, eaten away by the action of the lead. This could be prevented by securing the roses to a thin seating of teak, which might be jammed between the floors.

With regard to BOATS, I sometimes think that there is need of improvement. Your Clyde-built vessels are noted for their speed and beauty; and it has often occurred to me that in building your small boats you have been endeavouring to attain the same object; for, in some cases, the boats are nearly "all ends and no middle." It cannot be that the saving of material and labour is the object. Now, it is not at all necessary that small boats should have such very fine lines. Speed must give way to buoyancy and stability, and there is no reason why a good carrying boat should not be also a good-looking boat. Then, as to boat-building, undoubtedly the strongest boats are those which are built of two thicknesses of plank, worked in opposite diagonal directions; but I suppose that this mode of construction is too expensive to be generally adopted, even for ship's life-boats, and we must be content with the ordinary carvel or clincher-built boats. I am not by any means an advocate for boats which have to be suspended at davits being made excessively heavy; and if you will give me carefully-selected and well-seasoned material, and good fastening, I will not object to a little lighter scantling. I have seen excellent boats built of yellow pine; but for boats that may have to take the beach, rock-elm, or larch, or mahogany, is preferable, while for vessels going to hot countries it is desirable that the boats should be built of teak. In some new boats that I have examined, I have thought that the planks would have been none the worse if they had been allowed a little longer time for seasoning; and it would be better to clinch the sides of the nails upon roves than to turn them upon the timbers and landings.

The following description of a life-boat is extracted from the Instructions issued by the Emigration Commissioners to the Surveyors appointed under the "Passengers' Act, 1855:"—"The life-boat should be built whale-boat fashion, both ends alike, and the ends, to a limited extent, should be enclosed and made air-tight. It should have a sheer of about three-quarters of an inch to a foot, rising equally from amidships to the stem and stern. It should be fitted along the sides, under the thwarts, with strong metal or gutta-percha air-tight tubes of about 10 in. diameter, diminishing to 7 or 6 in. at the end cases; and of convenient lengths—say about 2 or 3 ft. each—and properly cased in. Life lines should be fixed along the outsides of the boat, and six life-belts for the crew should form part of its equipment." I may mention that the life-boats of some large ocean-going passenger steamers are supplied with a binnacle and compass, fixed under the after-thwart, and I think that this is an arrangement which should be more generally carried out. Two water-breakers, the water in which ought to be frequently changed, should form part of the equipment of every life-boat.

I am often asked about the BUOYANT APPARATUS, and I always say that I prefer strong copper tubes, strapped up firmly under the thwarts and exposed to view, so that it can be seen at any time whether they are perfect or damaged. I object to the practice of boxing up. Sometimes zinc tubes are surrounded by cork and enclosed in canvas bags; but I have found, even in new vessels, that this has not been a buoyant but a sinking apparatus, from the fact of the tubes havin- been cracked or burst by the workman when ramming in the cork; and, even if this should not be the case, it is well known that when a tube is so snugly stowed away out of sight it is not so easily examined, and it may become useless from corrosion before its uselessness is discovered. If I cannot have strong copper tubes, made of from 40 oz. to 60 oz. copper—that is to say, if owners will not pay builders to put copper tubes into the boats—then let me have large, strong, well-painted canvas bags, filled with good dry cork, for it is not such a serious matter to have these opened and the cork renewed, if wet should have found its way amongst it.

It is very seldom that I have to complain of boats' davits being too heavy. If builders would bear in mind that, not only ought the davits to be of sufficient strength to lower the boat and its equipments, but that they ought to be strong enough to lower the boat full of people safely into the water, and that, sometimes, from the surging of the falls, they are subjected to a dangerous jerking or springing motion, I am sure they would have them made of larger diameter. They could then afford to give them a little more length outboard, and thereby allow sufficient clearance to prevent the landings of the boat catching against the rail or gunwale-moulding or rubber on the ships' side. The strength of a davit depends, of course, to some extent upon its form, but I have found, from trial, that boats of the following proportionate dimensions are efficient, and that davits of the diameter corresponding thereto are sufficiently strong:—

Description.	Length over all.	Breadth over all.		Depth from Gunwale to top of Keel.		Contents.		Diameter of Davit.
	Ft.	Ft.	In.	Ft.	In.	Ft.	In.	In.
Life Boat ...	30	8	4	3	4	833	4	5½

Dingy.........	14	5	0	2	0	140	0	2¾

If I say anything about the PATENT APPLIANCES FOR LOWERING, it will be to express a wish that the boats to which they are fitted should be got out and lowered even at more frequent periods than when they are finished with only the ordinary tackles. Clifford's is a valuable invention, and the crews would have greater confidence in it if each man of them were to be taught its mode of application by being made to lower the boat with it himself; but it becomes worse than useless if, as I have known to be the case, the nib of the pendant between the friction rollers is allowed to get set so hard and fast that fomentations of hot grease have to be applied before it will move. The disengaging apparatus of Wood and Rogers is very safe and simple, and Gladstone's is even more easy of application, and less liable to get out of order; but I have seen the efficiency of the former destroyed by the pin and lever having been allowed to get rusted up, and when I had a boat lowered that was fitted with Kynaston's patent hooks, one hook performed its office, and let its end of the boat into the water, while the other stuck fast, and, from sheer neglect, the very aim and object of the patentee was defeated. One of the most simple and ingenious methods of freeing a boat from the chocks is that which I believe is nobody's patent, but which has been fitted to some half-dozen vessels at this port. The outer chock or half-chock, is kept in its position against the bottom of the boat by an iron quadrant, which rests upon a trigger bolt at the underside of the beam or skid, and when this trigger bolt is withdrawn, the chock falls down and the boat can be immediately swung out.

In well-disciplined ships I have had the boats, even with the ordinary tackles, got out and lowered in a most efficient and expeditious manner. The good discipline was the secret of the success; and although I am fully sensible of the difficulties attending the organization of a new crew, and of the amount of ordinary work which crews have to perform, I would impress upon the owners and masters who are present the advantage that would be gained by their establishing a rule, the observance of which would in a short time be regarded as a part of the regular duty, that at stated periods or what would be better still, that at unexpected times, at sea and in harbour, the men are to be exercised in getting out the boats, and that the patent appliances and locking-pintles of the davits are to be examined and worked at least once a-week.

(To be continued.)

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to M. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of his good faith.

RECEIVED.—G.F.W., H.B. and B., N.B., E.E.W., Capt N.P.F.A., S.H., R.W., W.A., I.N., G.B. (next week), W.P.M., R. and Son, S.E.

J. B.—Such an article would be acceptable.

H. BENNETT.—There are several modes of obtaining hydrogen gas. The easiest way for you would be to submit iron or zinc filings to dilute sulphuric acid. The hydrogen is evolved from the water, and the oxygen combines with the metal.

T. S.—It is very probable that there is a corrosive galvanic action going on between a brass propeller and the hull of an iron ship.

A MECHANIC.—The invention of the slotting drill has been claimed by a number of engineers. We should be inclined to give the palm to Mr. Richard Roberts.

F. E.—Very probably; an apparatus such as you propose would be appreciated at so small a cost.

L. M. B.—The safest plan is to patent your invention, and you can then get somebody to try it.

T. SMITH (Newcastle.)—No.

Correspondence.

◆

THE ATLANTIC TELEGRAPH.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Being extremely interested in the advance of Geographical science, and being tied to my chair and the country with an attack of gout, may I ask that the MECHANICS' MAGAZINE may be the medium by which I may make a few remarks on the paper read by Dr. Wallich at the Geographical Society on the 12th ult., and of which I take your report in the number of the 16th ult. as conveying the substance.

Dr. Wallich proposes that two steamers shall take a line of parallel soundings of 2 miles asunder between Ireland and Newfoundland, each ship sounding every 5 miles so that each sounding shall be 2½ miles apart, and this for the purpose of ascertaining the nature of the bottom in order that a telegraph cable may be so constructed as to meet the requirements of the bed on which it is to lie; and the doctor estimates that this can be done in five or six months, and he says that this line can be kept.

Admirals Elliott and Sir E. Belcher stated that the scheme was both impracticable and useless, and I naturally thought that, with such a decision from such authorities, the learned doctor would have been satisfied; but no, for on reading the report of the paper read by Mr. Massey, at the Society of Arts on the 28th ult, I was surprised to see that the doctor reiterated his assertions that "it could be done, and that, as such a line of soundings was necessary, it ought to be done."

Dr. Wallich has, I know, been to sea; but, perhaps, he was like "Lord Anson, who had been all over the world but never in it;" but the doctor must have seen some little of the difficulty of keeping a ship in position, and how much she went out of her course one way or the other. Is he aware of the value of astronomical observations at sea? How near latitudes and longitudes can be determined by observations of the moon or stars? Does he know that longitudes by chronometers are dependant on latitudes taken some hours before or after? Does he know the value of dead reckoning when these observations cannot be obtained? If he does, can he say that a belt of two miles can be run straight and correctly across the ocean? If he says it can, and he can do it, we old "salts" may shut up, for he can do more than any seaman in the kingdom, or I may say the world. I say it is impossible, and even to do it approximately, I affirm that it would take nearer five or six years to accomplish than as many months.

But we will suppose for the sake of argument that it can be done and is done—and we know the nature of the bottom at every 2½ miles on a 2 mile belt to America—and he has his cable made to lie on it, heavy cable for rock, a lighter kind for mud and so on. The cable shipped, who is to run it along his belt, taking care that each part shall be paid out on its particular bottom—for five miles on either side of his belt may throw all his calculations out? A ship with a cable paying out (unlike the sounding ships) cannot wait for observations, she must proceed, sun or no sun; perhaps the doctor says this can be done.

Dr. Wallich stated that "a sounding of 100 fathoms had been taken by Lieut. Sainthill, R.N., within about 32 miles of one of 3,000 fathoms taken by Captain Dayman." Not having heard of Lieut. Sainthill or his soundings, I referred to the "Navy List," and saw that the lieutenant is one of 1816, and on the reserved list, and that the case stands thus:—Captain Dayman had obtained a sounding of 3,000 fathoms, within 32 miles of one of Lieut. Sainthill of 100 fathoms. There may not be any great distinction between the two modes of expressing the fact, but there is a vast difference.

But with regard to the doctor's belt of soundings, had Admiral Elliott, or Sir Edward Belcher, got up and assured the meeting that all the doctor's foraminifera and diatoms, were nothing but young oysters, there is no doubt but that Dr. Wallich would have thought that, however good seaman the gentleman might be, he knew nothing of Natural History, and he would be right; and if he judged of either of those gentlemen's seamanship by his knowledge of Natural History, he would have but a poor idea of his abilities in his profession. Are we to judge of Dr. Wallich's Natural History by his seamanship? If so, the marker at page 72 of his "North Atlantic Sea Bed," now on my library table, may remain there for the next generation to go on with, and Part II., which we are promised, may go to the trunk-makers for me; but I do happen to know that the doctor is a clever naturalist, and I also do know that the admirals referred to know *their* work and are clever seamen, and navigators; therefore, in their respective specialities, I know how to value their opinion; but it shows to what visionary lengths men will go when they step beyond their own special calling, and I have only to refer to your number of Dec. 5th, and the scheme proposed by the same gentleman, Dr. Wallich, viz., to place moorings with submarine buoys across the Atlantic to support the Telegraph Cable, and I can only say that when the doctor has found his buoy of sufficient size that will not collapse to support four miles (two to each anchor) of mooring cable, and has laid his first *double* pair of moorings, I will then credit his ability to carry his two mile belt of soundings across the Atlantic—and not till then.

And now, Sir, may I add a few lines on the doctor's "North Atlantic Sea Bed." I own to being an officer in the Royal Navy, and I am naturally jealous of the honour and credit of my cloth, and knowing how much the navy has contributed to Natural History Science, and as the doctor had obtained all the specimens on which he founds his work while on board a man-of-war, I naturally looked for some expression to that effect, at first I did not read the whole of the title page, but I see on looking for it that he states that the "Bulldog" was commanded by Sir Leopold M'Clintock, but in his chart the soundings for which he must have taken from Sir Leopold's observations, there is no acknowledgment otherwise than that they are the "Bulldog's," and in the whole work I can see but two references to Sir Leopold, one, where the doctor submitted to him some adaptation of a clam, and the other where he accompanied the captain up a fiord, and the only acknowledgment I can find of any assistance rendered, is that to Mr. Roughton for making him a dredge.

I believe it to have been impossible for the doctor to have been four or five months on board that ship without receiving assistance, and great assistance, from others, and I am only sorry for the sake of Natural History Professors generally, that the doctor has withheld that common courtesy of acknowledging what is justly due to others, for it will make naval men very chary of rendering assistance when even the small meed of thanks is withheld. Let me refer Dr. Wallich to the Preface of Charles Darwin's "Naturalists Journal of the Beagle's Voyage," if he wishes to see what he ought to have done.

I may add that I do not know Dr. Wallich. I have never seen him, so that I have no personal feeling to influence my comments, they are purely professional. I am, &c.,

AN OLD SAILOR.

January 31, 1863.

PHOTO-ZINCOGRAPHY.

SIR,—In the MECHANICS' MAGAZINE of the 23rd of January it is stated that the folio Shakespeare of 1623 is in course of reproduction at the Ordnance Survey office, by permission of the War Department, and at the instance of Howard Staunton, Esq., of the *Illustrated London News*. As this is not the fact, and no one connected with this office has anything to do with the reproduction of that work, I shall feel obliged if you would insert in your next paper this contradiction of the statement which is calculated to mislead the public. It is also stated that no tangible recognition of Mr. Osborne's services, as the independent discoverer of photo-lithographic process, which is very analogous to the process I have named photo-zincography, was ever made by the Government. But the fact is, Mr. Osborne has not only secured a patent for his process in Australia, but has also received a very tangible recognition of his services from the Government of Victoria in a grant of £1,000.

But no one connected with this office has attempted to secure any advantage to himself by taking out a patent, or sought or obtained the slightest pecuniary reward for our discoveries. We are content with the knowledge that the public appreciate our labours, and recognize the efficiency of the department.

I beg to thank you for the complimentary manner in which you have been pleased to notice the work I have recently published on zincography, a second edition of which is now ready for issue, and which contains an account of the modifications in the process necessary to produce prints with gradation of shade or half tone in permanent ink from a photograph of any subject. I enclose you some specimens of prints with half-tone.

I am, &c.,

HENRY JAMES, Col. R.E.

Ordnance Survey Office, Southampton.
February 2, 1863.

A NEW SUBSTANCE AS FOOD.

SIR,—Voltaire, in his "Dictionnaire Philosophique," tells us that a beggar, asking alms in the suburbs of Madrid, a passer by says to him, "Are you not ashamed to follow that infamous employment, as you are able to work?" "Sir," replied the beggar, "I ask your charity, and not your advice." The poor, proud wretch did not consider (which is undoubtedly true) that more charity to the poor may be sometimes shown in giving them good advice than in giving them money. Such advice, when provisions bear so high a price as they do now, is more especially seasonable. Now, sir, all the gums are highly nutritious. A little, frequently dissolved gradually in the mouth, allays thirst and hunger. Soldiers, shut up in a fortress, could be kept alive many weeks with no other sustenance than gum-arabic, or cherry-tree gum. It is a powerful remedy in dropsy, from its affinity for water. In epidemic seasons, and as a preventive against ague, it may be used as an antiseptic, as it defends, or sheathes, the coats of the stomach against malaria. It braces up the nerves and lax-fibres of the corpulent, and reduces obesity. Dissolved in beef tea, the worst cases of debility are soon conquered. I am, &c.,

London, Feb. 4, 1863. JAMES BRUCE.

REPAIRING THE GREAT EASTERN.

SIR,—In my letter to you on this subject on the 10th ult., I remarked that it was "amusing to see the resuscitation of this plan after an unknown existence of 40 years." I have since learned that this identical plan was repeatedly used by Mr. John Maxton, for the Egyptian Government, some fifteen or twenty years since, and is also in constant use by Mr. B. Jensen, at Dantzic.

I am, &c.,

CHAS. F. T. YOUNG, C.E.

7, Duke-street, Adelphi, Feb. 2, 1863.

Meetings for the Week.

MON.—*Royal Geographical Soc.*, 1, "Inundations of the Nile," by Consul S. S. Saunders. 2, Report, by Dr. Baikie, "On the Countries in the neighbourhood of the Niger." 3, "Notes on Madagascar," by Lieut. Oliver, R.A., at 8.30 p.m.

TUES.—*Inst. Civil Engineers*, "On the Sleeper Woods, Madras Railway," "Description of the Drainage of Dundee," by John Fulton, and "Description of Drainage Works of Newport (Monmouthshire), by Mr. A. Williams, Assoc. Inst., C.E., at 8 p.m.
Royal Inst., "On Animal Mechanics," by Prof. Marshall, at 3 p.m.

WED.—*London Inst.*, Conversazione.
Soc. of Arts, "On the Construction of Twin Screw Steam Ships," by Capt. T. E. Symonds, at 8 p.m.

THUR.—*Royal Inst.*, "On Chemical Affinity," by Dr. E. Frankland, F.R.S., at 3 p.m.
Antiquaries, at 8.30 p.m.
Royal Soc., at 8.30 p.m.

FRI. — *London Inst.*, "On the Chemistry of the Non-Metallic Elements," by F. Field, Esq., at 7 p.m.
Royal Inst., "Artificial Illumination," by Dr. E. Frankland, at 8 p.m.
Architectural Assoc., "Class of Design"—"Public Fountain."

SAT. — *Royal Inst.*, "On Life and Death," by W. S. Savory, Esq., at 3 p.m.

Gossip.

On Saturday afternoon an influential meeting was held in Newcastle-on-Tyne, the Mayor in the chair, with the object of forwarding the business connected with the meeting of the British Association in Newcastle, in August next. The nomination of Sir W. J. Armstrong as president; Sir Walter Trevelyan, Mr. N. Wood, Mr. H. Taylor, Mr. I. L. Bell, and Professor Chevalier, as vice-presidents; Captain Noble, Mr. Hunt, and Mr. Clapham, as secretaries; and Mr. Hodgkin, as treasurer, was confirmed. Very influential, local, executive, and general committees were appointed, and it was determined to hold the meeting on the 26th of August. A subscription list was opened at the meeting, and nearly £1,000 was put down.

At a meeting of the Royal National Life-boat Institution, held on Thursday, the 5th inst., at its house, John-street, Adelphi, rewards amounting to £254 15s. 6d. were voted to the crews of its life-boats, and to shore-boats, for rescuing 98 persons from different wrecks during the late fearful gales on the coast. The Institution also voted £1,210 to pay various expenses on its 123 life-boat establishments. The committee earnestly appealed to the public for continued help.

An extraordinary trial has taken place this week between Mr. Clare and the Crown; the trial not having concluded at the time we were making preparations for going to press, we shall offer some observations on the subject next week.

At the meeting of the Mersey Dock Board, on Thursday, last week, a lengthy discussion took place upon the subject of the approaches to the landing stages, so long a crying evil to all who have to cross the river. Ultimately it was resolved that the plan of Mr. Lyster, the dock engineer, should be submitted to the Finance Committee of the Corporation. Mr. Lyster's plan, if carried out, will cost about £500,000.

It was understood that the foot-bridge over the Welland, near the Stamford terra-cotta works, for the convenience of persons having business at the Great Northern Station, would be completed by the 1st. inst. The stone-work has been completed some time, but the iron-work has not yet arrived from the contractors, Messrs. Cliff, of Bradford. We are now informed by Mr. Wright, the engineer, that it was not possible to procure the iron from the rollers for two months after signing the contract, though ordered at the same time, but that in the course of a few days the girders may be expected in Stamford, after which the bridge will be soon completed.

A letter from an officer on board the United States steamer "Bibb," off Charleston, says that Fort Sumter has been plated with railroad iron.

The first train of cars that had ever passed from the State of New York to the State of Ohio, arrived at Warren on the 11th January last, by the Atlantic and Great Western Railway, it being the only line of unbroken gauge between the two States.

A telegram from Constantinople states that the concession, with a guarantee of 8 per cent. on the capital of £1,200,000 for the first section of the Euphrates Railway (from the mouth of the Orontes to Aleppo, 90 miles), has passed the Council of Ministers, and that the firman will issue forthwith.

London Sewage.—A correspondent states that the salts contained in the "bulky fluid" may be solidified by means of plaster of Paris, or a mixture of the same with peat ashes, which contain gypsum. Made into cakes, they would keep a long time without smell; and, when used, should be coarsely powdered, the nitric acid of rain-water being all sufficiently powerful to dissolve any solid manure. London sewage, with its admixture of offal, &c., requires further admixture with a milder substance, like gypsum, which is not only an excellent stimulant to roots and plants to which it adheres, but is a powerful deodorizer. Night soil imparts a biting and acrimonious taste to radishes and turnips. Cabbages are less sapid and delicate. Potatoes borrow its foul taint. It has been traced to the onion. Millers perceive a strong and disagreeable odour in the meal of their wheat grown on it. It imparts a disagreeable flavour to asparagus and tobacco. It seems as if some portion of the foul matter of the night soil is absorbed by the vegetable's *radicles*, and, after passing unassimilated through the sap vessels, is converted, by the process of nutrition, to living substances. Ducks owe their offensive taste, at table, to it.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 1982.
Boilers and Furnaces, 1980.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1956.
Ships and Boats, including their fittings, 1972, 1995, 2000.
Cultivation of the Soil, including agricultural implements and machines—*none.*
Food and Beverages, including apparatus for preparing food for men and animals, 1941, 1981, 1984, 1987.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1936, 1946, 1952, 1963, 1996, 1997, 1998, 1999.
Buildings and Building Materials, 1948, 1992.
Lighting, Heating, and Ventilating, 1933, 1934, 1942, 1953, 1955, 1957, 1958, 1970, 1979, 1989.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1931, 1932, 1938, 1943, 1945, 1949, 1959, 1969, 1971, 1976, 1978, 1983, 1990, 1993.
Metals, including apparatus for their manufacture, 1935, 1947, 1950.
Chemistry and Photography, 1940, 1944, 1962, 1988.
Electrical Apparatus, 1960.
Warfare, 1937, 1966; 1985.
Letter-Press Printing—*none.*
Miscellaneous, 1939, 1951, 1954, 1964, 1965, 1967, 1968, 1973, 1974, 1975, 1977, 1986, 1991, 1994.

1931. J. Murray. *Improvements in portmanteaus.* Dated July 2, 1862.

This consists in fitting and applying the inner hinged flaps that enclose the compartments or divisions of the portmanteau with the hinges or jointed parts at or near the side adjoining the lock, or the fastening of the portmanteau, instead of being near the line of its hinges as usual. *Patent completed.*

1932. J. Steel. *Improvements in water-closets.* Dated July 2, 1362.

In a modification embodying these improvements, the bottom of the basin communicates by a short branch pipe with what may be called the discharge valve box forming the top of the soil pipe. The discharge valve consists of an elastic or flexible material, such as rubber, strengthened at the back; and it is fitted inside the valve box so as to be applied against the opening thereinto of the branch from the basin, this opening being, by preference, fitted with a brass ring projecting slightly inwards to form the valve seat. A kind of plunger is contrived to work up and down in the valve box by a rod passing up through the cover to the usual handle, and this plunger is hooked or jointed to the valve so as to open or shut it, accordingly as it is moved up or down. The plunger is, by preference, guided by means of grooved anti-friction wheels running on guide flanges formed or fitted inside the valve box, and the plunger is also, by preference, fitted with an anti-friction wheel, by which in descending it presses on the valve, and ensures its being completely closed. The valve supply is made self-acting, the supply taps being opened by a lever and float. The float is contained in a compartment provided at the side of the basin, the compartment communicating with the bottom of the basin, or with the branch therefrom, so that, when the discharge valve is opened, the compartment is emptied along with or immediately after the basin, and the float, descending in consequence, opens the supply tap, and the water flows in until the float is again raised by the basin and compartment becoming full. *Patent abandoned.*

1933. J. Crisp and J. W. Elliott. *Improvements in apparatus for burning American oil, paraffin oil, oil of petroleum, and other inflammable oils, spirits, or essences.* Dated July 2, 1862.

The object of these improvements is to obtain security in the burning of American rock oil, paraffin oil, oil of petroleum, and other inflammable oils, spirits, or essences. The material to be burned is placed in a cistern or reservoir through a feed hole, which may be closed by a screw or other plug, having an air hole in it, which, when required, may be protected internally or externally by wire gauze. From this reservoir a pipe conveys the fluid to another tube or chamber, which is closed partially at its lower end by wire gauze, perforated lead, or other suitable substance, and is of size sufficient to receive the wick and burner. For convenience of cleaning the parts of the tubes, the patentees connect them together by screw connections. The passage at the connection of the lower tube with the wick tubes (any part of the lower tube will do) is, by preference, partially closed by having only a very fine perforation or perforations through it of some length, or by the application of a coil of fine wire gauze, or a handle of wires or otherwise, through which the oil is regulated or filtered in its passage to the wick. The part of the tube occupied by the filtering media may be considerably varied to the form or construction of the apparatus. That part of the tube which holds the wick and burners is partially closed at its lower end by some perforated substance, and is made of such a depth as to allow of only a portion of the oil contained in the tubing or apparatus being consumed. By these means the interposition of a column of oil between the flame of the burning oil and the explosive vapour of the reservoir is secured. *Patent completed.*

1934. J. Webster. *Improved apparatus for the manufacture of gas for illumination.* Dated July 2, 1833.

In carrying out this invention for generating gas from solid substances, the patentee finds it convenient to place a worm wheel on the upper end of the axle of the vertical screw, which should be made to fit, or nearly so, the sides of the retort. Into this worm wheel gears a snail or worm, on one end of the axle of which is a crank or winch handle, whereby the worm is rotated, so as to give a slow rotatory motion to the vertical screw for the purpose of carrying down the carbonaceous matters in the retort, which is surrounded by the fire in the fire-place. The upper end of the retort is open, and terminates in a hopper which is supplied with the coal or other carbonaceous material. The lower end of the retort is also open, and terminates in a close chamber below, into which the coke is discharged by the rotation of the screw. The gas, as it is driven off by the heat of the fire, also passes down inte the close chamber below, and is drawn off therefrom into a condensing or cooling apparatus, which consists of a vertical column of suitable height, provided internally with a vertical screw which fits the interior of the column, and therefore divides the capacity of the other into a helically-formed passage, along which the gas is made to pass into a syphon pipe, and from thence through a purifier into a gas holder' *Patent completed.*

1935. G. Bedson. *Improvements in rolling wire and other rods or bars of metal.* Dated July 2, 1862.

This refers to that kind of rolling in which the metal is alternately rolled from one form into another. According to one part of the invention the patentee avoids the necessity for turning the metal by using a series of rollers placed alternately at right angles, or other angle to each other, and so that the metal, as it is delivered from one pair, may be taken up by the next, for which purpose he places guides leading from one pair to the other. Another part of the invention relates to a method of causing the rod to be turned. For this purpose he uses a guide, by which the metal is caused to move in a spiral direction, and so present another face to the next pair of rollers. *Patent completed.*

1936. J. M. Hetherington and T. Jackson. *Improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.* Dated July 2, 1862.

This relates, 1, To the lubrication of spindles of preparing, spinning, and doubling machines. The spindle turns at its lower end in a footstep, which has a chamber formed around it, provided at its lower end with a hole or holes, through which lubricating material may pass from the said chamber to the spindle. Another part consists in a method of obtaining the "drag" for the ordinary throstle bobbins, which are carried to the spindles, and not by tubes. To effect this drag the patentee uses a plate of metal, which revolves with the bobbin by a pin or other such connection. This plate is bevelled from its outward part towards the centre, and is furnished with a projection extending into the bobbin. *Patent completed.*

1937. T. Turner and W. Taylor. *Certain improvements in single and double breech-loading firearms.* Dated July 3, 1862.

This consists in securing the stock and barrel together, and opening the breech end by a lever secured on the one or both sides of the breech end of the barrel or barrels, having a strap that extends back on the top of the stock to the part that is encompassed by the hand of the user in the act of discharging. The breech end of the barrel or barrels forms the segment of a circle, the radius of which is equal to the centre of the axis on which the lever works, that portion of the lever that abuts against and screens the breech being also of the same radius. On the inside or sides of the lever that encompass the breech of the barrel or barrels (in connection) are dovetailed recesses, and these being formed of the same curvature, of which the axis before referred to forms the centre, great strength is afforded for securing and holding the surfaces for closing the breech end of the barrel in positive contact, and not subject to any variation from expansion of the metal while in use. *Patent abandoned.*

1938. G. H. Birkbeck. *Improvements in the construction of mechanical horses.* (A communication.) Dated July 3, 1862.

The object here is the combination of various parts into a mechanical horse, to enable equestrians to acquire a secure and solid seat, which at the same time is supple and elegant, together with a fine hand. *Patent completed.*

1939. W. A. Gilbee. *An improved manufacture of blue colouring matter.* (A communication.) Dated July 3, 1862.

The patentee claims, 1, The manufacture of blue colouring matter by rosaniline set free, as described. 2, The use of ordinary sulphuric acid of commerce in the hot state to render the blue soluble in water, as described. 3, The use of alkalies to form bluine, and its conversion into salts susceptible of giving a blue colour, as described. 4, The process or means described for obtaining a blue and blue purple colour, applicable for printing or dyeing on silk, wool, cotton, and other materials, by employing water or ordinary nephilated alcohol for dissolving the colours. *Patent completed.*

1910. W. M. Williams. *Improvements in apparatus for the distillation of coal and peat, and such other substances as are or may be used, for the manufacture of solid and liquid volatile hydro-carbon.* Dated July 3, 1862.

The object here is to produce the maximum of liquid hydro-carbons, and also a good coke or charcoal, by conducting the distillatory process in a progressive manner, and consists in certain improvements in the distillatory apparatus by which the gradual heating of the substance under treatment is effected. The products of the distillation at different temperatures may be separated when required, and a good coke or charcoal obtained. *Patent completed.*

1941. T. Edmonds. *Improvements in preparing compressed fruits in cakes.* Dated July 3, 1862.

This consists in the application of a surface of confectioner's wafer material on the top and bottom of such cakes, which may be also applied at other parts of the exterior of such cakes, and which may be embossed, pressed, or otherwise ornamented. *Patent abandoned.*

1942. T. O. Dixon. *Improvements in means or apparatus for heating or warming rooms or buildings with steam, and in carrying off the condensed steam or water therefrom.* Dated July 3, 1832.

This consists, 1, in arranging the steam pipes, or the pipes for conducting and circulating the steam for heating or warming rooms, so as that the condensed steam or water may be drawn off into a receiving pipe at various points in the line or circuit, and be conducted thence to a syphon box or steam trap, steam being also conducted by a separate pipe thereto from the end of the line or circuit, by which arrangement breakage of joints in the pipes is prevented. 2, In the use of an equlibrium valve in combination with a float lever in the syphon box or steam trap, by which the condensed steam or water is carried off, or is permitted to escape without allowing any steam to pass off. *Patent completed.*

1943. J. Miles. *Improvements in machinery for cutting out soles and other parts used in the manufacture of other articles.* Dated July 3, 1862.

Here cutters of the forms of the intended soles are fixed to the under surface of the rising and falling platten of a press, which is put in motion by two connecting rods and two cranks on a shaft driven by hand or other power, there being a fly wheel on the pinion shaft. Two cutters are used, formed to cut the sole for the right and for the left foot respectively. The leather or other material used for forming soles is moved laterally alternately from one cutter to the other, by which waste of material is prevented. The material used for making soles is placed on a bed formed with a surface of lead, wood, &c. where each of the cutters comes, and there are stops or guides to aid in placing the material correctly. An instrument actuated by a cam clears the bed of any bits of the leather that might interfere with or obstruct the action of the cutters at the next cut. The correct height of the bed of the press is regulated by set screws or other convenient means. When other parts of boots or shoes, or parts of other articles are to be cut by the press, other cutters are to be introduced and fixed to the platform in place of those above named. *Patent completed.*

1944. S. Russell. *Improvements in stereoscopes.* Dated July 4, 1832.

Here the inventor makes the stereoscope in the form of a box of a suitable size for holding the pictures, the length of the box being slightly in excess of that of the stereoscopic picture to be used with it, and its depth slightly in excess of the width of the pictures, so that the interior of the instrument is conveniently used as a case to contain pictures, and there is nothing to prevent its being entirely filled with them; the instrument is closed when out of use by a lid sliding in grooves in its two ends or shorter sides. Against the front of the box, and within it, a mirror is fixed, and the lenses or eye-pieces are mounted in apertures in the lower part of the back thereof, and they are inclined so as to be directed nearly towards the horizontal centre line of the mirror. The picture to be viewed is placed in a ledge at the back of the interior of the case, and immediately over and close to the eye-pieces, and it is inclined somewhat so as to bring the reflected picture perpendicular to, or at right angles with, the line of sight, and to accomplish which by this arrangement the picture need not form an angle of more than 16 deg. or 17 deg. with the mirror. The light falls directly on the picture, entering at the open top of the case; and to admit more light to the picture he makes the portion of the front of the case over the mirror, together with a small portion of each of the sides, to turn back on hinges, and this piece, when turned, also serves to support the picture, its upper edge resting against it. *Patent abandoned.*

1945. W. J. Cunningham. *Improvements in sewing machines.* Dated July 4, 1862.

This invention applies to those sewing machines wherein two threads are used, one above and the other below the work, and the invention consists in means (the details of which we cannot here devote space to) for working button and other holes. *Patent oompleted.*

1946. A. Drevell. *Improvements in machinery or apparatus for laying cords or sheets of metal into woven or textile fabrics ready for the press, and also for folding, measuring, or stretching the said fabrics, paper, and other materials.* Dated July 4, 1862.

This invention comprises, first, new arrangements for folding; secondly, new arrangements for feeding forward the cards; thirdly, means for raising the card tables, and, fourthly, the depression of the tissue and cards on the folding table, together with the retention of the said materials at their proper and constant level. *Patent completed.*

1947. S. Whitham. *Improvements in the manufacture of iron and steel, and the apparatus employed for that purpose.* (A communication.) Dated July 4, 1862.

This relates to ball, mill, and puddling furnaces employed in the manufacture of iron and steel, and consists in constructing or building such furnaces in pairs or double, with a stove or chamber formed in the neck thereof, to receive the metal preparatory to its being passed forward into the body of the furnace, and in applying a blast of atmospheric air to such furnaces which may be either hot or cold, as required, whereby the inventor obtains a more uniform heat, producing a better quality of the manufactured metal, with a larger yield; also effecting a saving in fuel and a diminution of manual labour. *Patent abandoned.*

1948. J. Howard and J. Bullough. *Improvements in warping and beaming machines.* Dated July 4, 1862.

This invention (the details of which we cannot produce here) consists in improved modes or arrangements for stopping the warping or beaming machine when one or more of the warp threads break. *Patent completed.*

1949. H. Rushton. *Improvements in covering crinoline steels.* Dated July 5, 1862.

This consists in applying a coating of Japan varnish, or other suitable varnish, upon steel for crinolines, so as to prevent corrosion or rust; and over the steel thus prepared the inventor plaits or weaves cotton, silk, or other fibrous material, so as to make an open work pattern that the varnish may be partially uncovered. *Patent abandoned.*

1950. R. A. Brooman. *An improvement in hollow plates for hydraulic presses.* (A communication.) Dated July 5, 1862.

This invention refers to hollow plates used for receiving a heating medium, and employed in expressing oils and in separating fatty and oily matters from steam in the manufacture of candles, and in similar operations. These plates have hitherto been made in several parts, united by joints and rivets, the result of which has been that fatty and other matters have entered and obstructed the passages within the plates for the circulation of steam or other heating medium, necessitating frequent repairs and cleansing of the plates. Now, this invention consists in making the plates in one piece of malleable cast iron, or of any other suitable metallic alloy, with apertures or channels of any desired shape, round, oval, square, spiral, or otherwise, for the distribution of the heating medium. In some cases the plates are made in top and bottom pieces, which are placed one on the other. *Patent completed.*

1951. O. F. Bystrom. *An improved pyrometer.* Dated July 5, 1862.

This relates to a pyrometer, which the patentee calls the hydropyrometer, from the fact that the temperature of the furnace, retort, muffle, or other heating arrangements to be tested, is indicated by the proportionate amount of heat imparted to a known weight of water by a body immersed therein, such body having been previously heated in the furnace, retort, or muffle to be tested to an equal temperature throughout. *Patent completed.*

1952. C. J. Hill and W. Jackson. *Improvements in machinery or apparatus for producing ornamental patterns or figures, and attaching them to lace or other fabrics.* Dated July 5, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

1953. A. Warner. *Improvements in preparing materials for, and in purifying coal gas.* Dated July 5, 1862.

Here the patentee employs the cinders, or oxide of iron, obtained from puddling, reheating, and refining furnaces used in the manufacture of iron, which cinders or oxide of iron he prepares and uses in place of, or in combination with, other preparations of oxides of iron heretofore employed for like purposes. *Patent completed.*

1954. P. B. O'Neill. *Improvements in screw wrenches or spanners.* Dated July 5, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1955. J. Kidd. *Improvements in gas meters.* Dated July 7, 1862.

This consists in the construction of gas meters for street and other lamps, and burners with one or two measuring chambers, instead of three or more, as meters are made at present, and also in combining with the meter a regulator by which a regular supply of gas is given to the burner at an unvarying pressure. The measuring chamber is placed in the interior of a drum or outer case, and may be worked as an ordinary bellows, or by mercury, as in a mercurial regulator, and is so arranged that, as it takes in and discharges the gas, it gives motion, by levers, to a mercurial level which it causes to turn upon a centre. *Patent completed.*

1956. C. Wersley. *Improvements in carriages.* Dated July 7, 1862.

Here the load and weight of the body of the carriage rests wholly or chiefly upon the nave of the carriage wheels, without bearing upon the axle-tree, viz., cranked axle-tree. This is effected by anti-friction wheels which bear upon the naves of the above-mentioned carriage wheels, and turn concentric around steel trunnions. These trunnions are fixed each in the upper part of a vertical piece of flat iron, the lower end of which encompasses by clutches the vertical parts of the crank axle-tree, so as to follow an up and down sliding of the former. Unto these pieces of flat iron the body of the carriage is attached either by springs, or directly. A knuckle is formed on the piece of flat iron just above the highest point of the axle-tree, so as to form a rest for the whole load upon the axle-tree, in case the trunnion of the anti-friction wheels should give way, and this may move on like common vehicles. *Patent abandoned.*

1957. T. Edwards. *Improved movement for the indices for gas, water, and other fluid meters.* Dated July 7, 1862.

The object here is the construction of a correct and cheap movement for gas, water, and other meters, which will be more easily read off than the indices at present in use, and the accuracy of the several parts may be readily tested by a templet or gauge plate. The improvement consists in substituting for the ordinary toothed wheels, and pinions, now ordinarily used, peculiarly formed wheels, and in casting them upon their shafts or arbours, and in casting or cutting the pinion of the worm motion with a milling tool, that the oblique and curved teeth on the periphery are of equal and uniform depth throughout, and in casting the framework in two pieces, with the holes ready to receive the ends of the shafts on the "arbours" and pillars. *Patent completed.*

1958. J. McGeary. *Improvements in the manufacture of gas, and in the apparatus to be employed for that purpose.* (A communication.) Dated July 7, 1862.

The grant of letters patent for this invention having been opposed at the seal, the document relating thereto cannot at present be seen.

1959. J. P. Booth. *Improvements in the manufacture of beds, quilts, bolsters, and pillows.* Dated July 7, 1862.

Here, in manufacturing feather beds, the inventor lines the tick or cover on its inner face with cotton or other wadding, and secures the wadding thereto by quilting. *Patent abandoned.*

1960. W. Spence. *Improvements in telegraphic apparatus.* (A communication.) Dated July 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1962. C. Gunner. *Improvements in photographic apparatus.* Dated July 8, 1862.

This consists in certain novel apparatus whereby the yellow or dark chamber can be entirely dispensed with. *Patent completed.*

1963. J. Brown. *An improved motion for actuating the doffers of carding engines for carding cotton and other fibrous substances.* Dated July 8, 1862.

These improvements are designed with the view to obtain a steady vertical motion of the doffer employed to ship the fibrous substance from the cards, and consists in securing each end of the doffer in a block sliding vertically in a pedestal. These blocks (and consequently the doffer) are actuated in a vertical reciprocating direction by rods or arms, moved by eccentrics placed upon a shaft beneath the pedestals. The peculiar feature of the invention is the use of the sliding blocks and pedestals for the purpose of steadiness. *Patent abandoned.*

1964. J. Russell, jun. *An improved arrangement and method of indication to be employed in railway and other time tables.* Dated July 8, 1862.

This consists in the use and application of stripes, dots, commas, or other marks or signs, to any or all of the division lines now used to separate the rows of figures denoting the time. For example, take the departure of a train consisting of one or two classes of carriages; this is denoted by marks or signs upon the division line, and the numerals usually employed for the purpose are discarded, and, consequently, the space they occupy is saved; then if an extra class is added to the train at a future station, it can be indicated at the point of addition by a mark, when a numeral would only tend to confuse instead of instruct. *Patent abandoned.*

1965. C. Slatford. *Improvements in trimmings, tufts, and other articles for ornamental and decorative purposes.* Dated July 8, 1962.

This invention consists in taking lamb's wool or sheep's wool while still adhering to the skin, and in shaping the skin according to the purpose to which the wool is to be applied, in order to impart the desired shape to the tuft or other article. The wool may be dyed any desired colour or colours, or may be used white. In some cases the inventor unites two or more skins having the wool dyed in different colours. *Patent completed.*

1966. J. Rigby. *Improvements in breech-loading guns, and in cartridges for such guns.* Dated July 8, 1862.

This relates to fitting and furnishing breech-loading guns, which open by moving the barrel out of the line of the breech on a vertical pivot, so that it shall move in the line of the breech until it is free thereof, and then swivel or move on its pivot. The inventor mounts the pivot in an eccentric piece fitted in a bearing in the breech piece, which is extended forward under the barrel for that purpose. On this eccentric is fixed or formed a hand lever, by the movement of which the sliding of the barrel is first effected, and by its continuance the barrel is deflected, and the breech piece exposed for the insertion of the cartridge. Instead of the pivot of the barrel having a rigid bearing in the eccentric, it may be in a slot bearing, and be further guided by longitudinal guides to maintain its parallelism during a certain part of the motion of the eccentric. The second part relates to a method of extracting cartridge cases from breech loading guns. *Patent abandoned.*

1967. O. W. Child. *A new and useful composition to be used in shaft journal boxes.* (A communication.) Dated July 8, 1862.

This composition is composed either of sulphur and plumbago, or the same and stealite, metalic oxides or sulphurets, the whole being capable of being fused, or reduced to a liquid state, and being run or cast into a box or bearing, so as to be used under the journal of a shaft in a similar manner to what is termed "Babbitt" metal is generally employed. *Patent completed.*

1968. J. Bourke. *Improvements in military accoutrements.* Dated July 8, 1862.

We cannot here give space to the details of this invention. *Patent abandoned.*

1969. H. Wethered. *Improvements in the construction of handles, latches, or fastenings for doors, gates, and windows.* Dated July 8, 1862.

This consists principally in the use of a lever handle, on the spindle of which is a tongue or short arm, which can be used single or double, and when brought into a horizontal position may be inserted into a slot or socket made in a catch plate, which is secured by screws or otherwise to the jamb or door-post. When the door is being shut, this tongue or arm of the lever handle is brought against an inclined projecting piece, which will cause the lever handle to assume a horizontal position before the arm or tongue can enter the slot or socket, and the door can be fastened. In order to do this the handle must be lifted up either by the projecting piece on the door or by hand, and the tongue or arm attached thereto must be pushed forward while in a horizontal position into the slot or socket, and when well clear of the projecting piece the lever handle and the tongue or arm on its spindle may be lowered into a vertical position in which it will remain while in a state of rest. *Patent completed.*

1970. W. L. Wigginton. *The cure of smoky chimneys.* Dated July 9, 1862.

This consists in the use of a lining for the sides of fire-places, with back and top, to which is attached a pipe with cap. The principle is this:—The cap will intercept the heat, become very hot, and rarify the air, around which, of course, a partial vacuum into which the denser air of the room will find its way, drawing the hot air before it. Thus, while the cause—the fire—remains, the chimney flue will be efficiently filled with a "flow" volume of hot air. *Patent abandoned.*

1971. J. M. Gille. *An improved calendar inkstand.* Dated July 9, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1972. T. C. Gibson. *Improvements in the construction of ships and vessels for the purpose of carrying and warehousing petroleum, palm oil, and other oils, or inflammable fluids.* Dated July 9, 1862.

This invention consists in building ships or vessels of iron, and of such a shape that the lower part of the hull, or the entire ship or vessel, forms a large tank, or cask, to contain the petroleum, palm oil, or other inflammable substances, either in a fluid or congealed state. In carrying or transporting petroleum, and other oils or fluids, the tank is entirely filled, thus dispensing with the casks now employed for transport. In warehousing petroleum, and other oils or fluids, floating iron vessels, of a cheaper construction than sea-going ships, are employed. These floating vessels should be moored in some convenient place, where the sea-going ship, with her cargo, may go alongside; the petroleum may then be removed by pumps, syphons, or other means, out of the sea-going ships into the floating warehouses. *Patent abandoned.*

1973. A. Gilbey. *Improvements in apparatus for washing and cleansing bottles.* Dated July 9, 1862.

This apparatus consists of a series of brushes, mounted upon a suitable frame, each fixed upon a hollow spindle, which, with the brush, revolves in the inside of a bottle to be cleaned. Through these hollow spindles, and by means of a general supply pipe, with which each one communicates, the patentee introduces a supply of water, which is carried into the inside of each bottle, and, by the action of the brushes revolving, is used to cleanse the inside of it. The bottle is placed slightly inclined from the horizontal plane, the mouth falling into a hollow metal box, through and upon which the hollow spindle is mounted, and, with the brush surrounding it, is passed into the interior of the bottle. The bottom of the bottle is laid upon a sliding seat, so as to regulate its position. The slide is held to its place by means of a spring, so that the bottle is steadied and held in its proper position during the operation. The hollow spindles, with the brushes, are caused to revolve by means of rollers, or pulleys and straps, or by any other well-known motion. When complete, the frame upon which the whole is mounted, is arranged so as to form a trough to receive the dirty water as it comes from the bottles after and during the operation. *Patent completed.*

1974. H. S. Pontifex. *Improvements in apparatus for distributing water, applicable to cleansing casks, or other vessels, and for other purposes.* Dated July 9, 1862.

This invention has for its object improvements in apparatus for distributing water, applicable for cleansing casks, or other vessels, especially that description of casks known as unions, or union cleansing casks, used in breweries, or for other purposes, amongst which may be mentioned extinguishing fires in cellars, or in the holds of ships. In applying the invention to cleansing unions, or union cleansing casks, the patentee is enabled to do away with the apparatus heretofore necessary to cause the casks to revolve when being cleansed, whereby a saving of 25 per cent. is effected in the cost of the construction of such unions, and the water used in cleansing the casks is not one-tenth of the quantity required where the unions revolve. For the purpose of carrying out this invention, he takes a tube of brass, by preference, one end of which is attached by a screw, or by simply tying to a hose-pipe supplied with water in any convenient manner. The other end is formed with a screw on it for a part of its length, for the purpose of carrying a spreader, or valve. Below the screw on the pipe, circular, longitudinal, or other openings, are formed, for the purpose of allowing egress to the water, and the end of the pipe is closed with a plug, which carries a screw on its outer part; on to this screw is fixed an inverted cap, made of copper, brass, or other metal, of larger size than the pipe; the end of the cap comes up to or beyond the screw above referred to, on the body of the pipe, and covers over the holes left in the interior pipe; this cap is curved towards the inner part at its extremity. On to the screw above referred to is placed the spreader, or valve; it is constructed to work on the screw, and has a flat flanged piece fixed to the screw, which is coned, to fit the cone on the cap, and, by screwing down close, can be made to effectually shut the aperture. This screw is fixed on to a pipe of suitable length, which is placed outside the water pipe, and moves freely round it. When working the apparatus, the pipe is dropped a proper depth into the cask, or other place, and, the screw being withdrawn or unscrewed, the water is delivered within the cask, or other place, as required. The adjustment at will of the opening between the cones, by means of the screw, regulates the height and shape of the jet or body of water delivered. *Patent completed.*

1975. J. Rhodes. *Improvements in rag machines.* (A communication.) Dated July 9, 1862.

This invention has for its object the prevention of bits or tufts of untorn-up rags from passing forward with the wool or fibre, and the improvements consist in forming an opening in the cover to the back of the swift, and placing an adjustable slide-plate therein, with a diaphragm or plate betwixt the cover and the swift, which is fixed at one edge to the cover; and, by means of adjusting screws, is set at a suitable distance from the periphery of the swift at the other edge. *Patent completed.*

1976. C. F. W. Rust. *Improvements in concertinas and other wind instruments of that class.* (A communication.) Dated July 9, 1862.

In this newly-invented concertina the notes or keys are arranged in their natural order or succession, as on a pianoforte, viz., C C sharp, D D sharp, E, F F sharp, G G sharp, A A sharp, B, and so on; moreover, the drawing out or pressing in of the instrument produces on the same key one and the same tone. The operation of playing on the instrument is by this arrangement very much simplified, as every tone has its universally known musical place, just where the musical feeling or instinct of the performer would seek it, and the pressing in or drawing out of the instrument need not be taken into consideration at all in playing. *Patent completed.*

1977. H. Eschwege. *Improvements in purifying wood and other vinegar.* Dated July 9, 1862.

The patentee claims the purification of vinegar (acetic acid), in its acid or neutralized state, by filtering the same in a diluted state, as described, through a series of charcoal filters, adding a fresh filter at the end, and disconnecting the first and foulest filter of the series, as explained. *Patent completed.*

1978. G. T. Bousfield. *Improvements in washing machines.* (A communication). Dated July 9, 1862.

In constructing washing machines according to this invention, a barrel or cylindrical wooden vessel is furnished with axes or trunnions, and these are supported by a wooden frame, so that the barrel or vessel is free to revolve end over end. A handle is fixed on one of the axes by which it can conveniently be rotated. At the top of the barrel or vessel a cover is fitted, which is capable of being secured watertight by a cross bar and pressure screw. Within the barrel or vessel a number of circular ribs are fixed against its sides and parallel to its ends. In making use of the machine the fabrics to be washed are placed in the barrel or vessel, together with a number of spheres of wood or stone, and soap and water. The cover is then put on, and secured by the screw and cross bar. The vessel is then rotated for a few minutes, at the end of which time the fabrics will be found completely cleaned. *Patent abandoned.*

1979. E. S. Hindley. *Improvements in apparatus used when circulating hot water for warming dwelling houses and other places, which apparatus may be used for cooling and condensing.* Dated July 9, 1862.

For these purposes, in order to obtain combined arrangements and clusters of tubular passages for the circulation of hot water, a series of tubes or pipes is cast or formed, each tube or pipe having at each of its two ends, or near each of its two ends, a hollow or tubular cross head, communicating with the interior of the tube or pipe of which such cross heads or ends form parts. The two ends of each of these cross heads or ends are made to fit other similar cross heads or ends on other pipes or tubes, so that when several of these cross heads or ends are brought and held together, a continuous tubular passage is produced at both ends of the series of tubes or pipes, and, by preference, at right angles thereto. In order to fix several of such cross heads or ends together securely and watertight, screw bolts are used, which are passed through the tubular cross heads or ends formed at the two ends of the several pipes or tubes. The screw bolts used are of smaller diameter than the interior of the tubular passages in the hollow cross heads or ends, in order that there may be sufficient passage-way for the free flow of water through the hollow cross heads or ends, and to and from them to the tubes or pipes of which the cross heads or ends form parts: or these bolts may be placed outside the said cross heads, and parallel to the direction of those through the cross heads. Between each joint or junction of the several hollow cross heads or ends is introduced a washer or filling piece, of vulcanized india-rubber, or of other suitable soft substance, so that when the nuts on the screw bolts are screwed tightly up to secure the several hollow cross heads or ends, the joints or junctions will be made water-tight. *Patent abandoned.*

1980. T. Green and R. Mathers. *Improvements in steam boilers.* Dated July 9, 1862.

For the purposes of this invention, in order that the steam passing from an upright boiler may be superheated, a tubular passage, arranged in a spiral direction, and in a conical form, is applied above where the tubes or flues come through the boiler from the fire-box, so that the heat and products of the fire as they rise to the chimney may pass against the exterior surfaces of the tubular passage, and highly heat all parts thereof. This will be the better ensured by reason of the coil being, as above stated, in a conical form, and conveniently with the apex or smaller end upwards. The steam coming from the interior of the boiler, by preference, enters the upper end of the highly heated spiral tubular passage, and having passed downwards through the conical arrangement, it passes through the steam-pipe or passage leading from the coil to the cylinder or cylinders, when such cylinder or cylinders are external of the smoke-box; but if the cylinder or cylinders be within the smoke-box then the steam is conducted to the valve-box or boxes of the cylinder or cylinders. In order to increase the heating surfaces of the fire-boxes of steam boilers, the patentees fix bent pipes to the roof or sides of the fire-box. Each bent pipe is formed into two similar limbs, and by preference of malleable cast iron, in order that near the end of each limb there may be a collar to come against the plate of the roof or side when the part which is beyond the collar has been passed through such roof or side plate. The ends of the two limbs are fixed by rivetting or upsetting the part of the tubes which pass through the top roof or side plates. These bent tubes may project into the water space, allowing the heat to circulate through them, or they may project into the fire-box or furnace, so as to be surrounded by the heat, whilst the water circulates through them. In constructing the regulating valves of steam boilers they apply a steam box or chamber on a steam boiler, to which box or chamber the steam supply pipe is fixed. In this box or chamber there is a rising pipe which is closed at the top, the lower end being open and provided with a suitable flange or boss for connecting the outlet pipe. *Patent completed.*

1981. S. V. Evers. *Improvements in the preparation of beverages.* (A communication.) Dated July 9, 1862.

In the preparation of one beverage, according to this invention, the inventor first boils loaf sugar in water, and having mixed the same allows it to cool. He then purifies it by filtration or otherwise, and mixes with it arrack, champagne, and lemon juice. The mixture is first well stirred with iron-stirrers, and then stored in suitable vessels for a certain time, adding to it white of egg. By these means an agreeable and refreshing drink may be obtained. *Patent abandoned.*

1982. J. O. Butler. *Improvements in steam hammers and in framings therefore.* Dated July 9, 1862.

This invention relates to the framing or supporting standards of steam hammers, and consists in making such framing or standards of wrought iron, in lieu of cast iron as heretofore. In some cases the standards may be constructed in one piece of wrought iron, and shaped either by forging under the hammer, or by suitable dies and pressure. For large hammers, the supporting standards would be composed of several wrought iron plates rivetted together, and straightened by angle T, or other suitably shaped bars, as is well known in the making of wrought iron structures. *Patent abandoned.*

1983. W. F. Reynolds. *An improved watch pendant.* Dated July 10, 1862.

This invention consists in passing the ends of the bow through the ball of the pendant, and securing the same by rivetting or otherwise, so as to prevent their return, the said ball being formed in two parts for that purpose, and employed in connection with the fixed pendant, or with a swivel movement and solid bows, the object being to strengthen the bow fastening, and prevent its being forcibly disengaged from the watch, a spring movement being also employed for enabling the bow to maintain its relative position to the watch. *Patent abandoned.*

1984. E. Jandeaux. *Removing the bad flavour from alcohols distilled from grain, beetroot, or other vegetables, and for extracting the whole of the alcohol contained in the fermented juice.* Dated July 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1985. H. Kellogg. *Improvements in breech-loading fire-arms and cartridges therefore.* Dated July 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1986. J. Mander. *Improvements in crochet needles and crochet needle holders.* Dated July 10, 1862.

This invention consists.—1, In fixing on that end of a crochet needle which is inserted in the holder a small piece of brass, or other material having an expanded end, or making an expanded end on the said needle, which expanded end can be forced into the spring part of the holder, and thereby effect a rapid and safe connection of the needle with its holder. In making a sliding crotchet needle holder according to this invention, the patentee takes a thin metallic open jointed tube or case of the kind used for making small pencil cases, and he connects the needle to the said case by means of a strip of sheet metal, which is bent at its middle into a tubular form. This tubular part grasps the before-described expanded end of the crotchet needle, by means of two or more spring clips situated on its edge. *Patent completed.*

1987. A. Bonnell. *Improvements in churns.* (A communication.) Dated July 10, 1862.

In carrying this invention into practice the patentee makes use of a suitable box or case, mounted on legs, which may be made removable if desired. Within this box or case he places a shaft, with beaters, the said beaters being projecting arms fixed on the shaft in such manner that they shall range as a twisted line or thread of a screw, or an approximation thereto; one end of this shaft comes through the end of the box or case, and has a toothed wheel thereon; the interior of the bottom of the box or case has projecting pieces running the whole length, and forming what may be termed a series of steps. Inside the case, and above these beaters, at the end where the beater shaft protrudes, is a circular case of zinc, or other metal or material, which has a hole at the top, and within side a number of projections or corrugations; and in this circular case is a disc similarly corrugated, which disc has an axis passing through the case, having a toothed wheel outside, this toothed wheel and the toothed wheel first described, being driven by another toothed wheel on a winch handle, such winch handle being provided with arrangements for throwing the same into or out of gear with the one wheel or the other, or causing the whole three wheels to work together. The case has a moveable top, and a plug to clear the churn, and in the top is an orifice communicating with the aforesaid circular case, fitting into which is a moveable feeding dish; into this the cream is poured, and the winch handle being placed in gear with the axle of the circular case only is made to rotate, when the cream will be acted upon by the rotation of the disc therein. The periphery of the disc being some little distance from the inner circumference of the circular case, the cream thus acted on exudes therefrom, and passes into the churn, where the winch handle is thrown out with the disc handle, and into gear with the beater shaft, and again turned; and when the churning is fully effected, it may be cleaned out by pouring in warm water, and placing the winch handle in gear with all the toothed wheels, causing them to rotate, when the hot water can be passed by removing off the plug aforesaid. *Patent completed.*

1988. J. Ponti. *An improved apparatus for viewing photographic pictures, termed an alethoscope, and in the preparation of photographic pictures to be used in such apparatus.* (A communication.) Dated July 10, 1862.

This invention consists in constructing an apparatus for viewing photographic pictures, resembling generally in form that of a stereoscope, but of considerably larger dimensions, and provided with only one large magnifying lens, and only one representation of the picture (which is also of considerably larger dimensions than those employed in stereoscopes). The object of the invention is to present readily to both eyes of the observer, without the inconvenience of looking through two separate lenses, a representation of the picture magnified to such an extent, and at the same time having the stereoscopic effect, sufficiently to impart to the same the appearance of the object itself in its natural size. *Patent abandoned.*

1989. E. J. Biddle. *The use of petroleum or coal oil as fuel, and also for the machinery and apparatus to be employed for this purpose.* Dated July 10, 1862.

The furnace, which may be of any suitable size and shape, is constructed of ordinary materials. Instead of the grate or bars now used, the bed of the furnace is constructed solid to prevent the escape of the fluid. This bed may be made either smooth or corrugated. The draught is obtained through a grating in the side or end of the furnace, which admits the air but confines the flames. And an additional supply of air comes to the flames through pipes terminating within the walls of the furnace. The oil enters the furnace at the bottom, and is at first ignited by surrounding the mouth of the pipe through which it passes with a small quantity of burning coals. A cap may be placed over the furnace for protection in case the flames should escape through the grating. Tanks for holding the oil are provided with pipes, which permit the escape of explosive gases, and render the use of this oil perfectly safe. These tanks are connected with each other and with a distributing reservoir, by pipes of a suitable size. A steam or hand pump may be employed to draw the oil from the tanks to a distributing reservoir. *Patent abandoned.*

1990. E. Townsend. *A new and useful invention for making nails, and driving such nails into the sole of a boot or shoe.* (A communication.) Dated July 10, 1863.

This invention is not described apart from the drawing. *Patent completed.*

1991. J. Leeming. *Improvements in Jacquard, or index, machines.* Dated July 10, 1862.

This consists in a simple and efficient arrangement and combination of the working parts of the Jacquard or index machine, whereby the patentee is enabled to work with either a double or single lift, and also to form a V shed, that is, to lift the back heald a greater height than the front one, and so cause less strain upon the warp threads. *Patent completed.*

1992. D. Steele. *Improvements in the method of flushing or distributing the water in pans, or basins, applicable to waterclosets, urinals, washhand-basins, or other purposes.* Dated July 10, 1863.

Here the inventor manufactures a pan or basin, of any ordinary form, and at or near the top thereof the supply pipe enters; and, as it enters the basin or pan, the aperture is contracted, so as to form a semicircle, containing only about half the area of the supply pipe. The effect of this contraction is to cause the water to be delivered in a suitable way, and at an accelerated speed, into the distributing portion of the pan or basin. The distributing portion is, by preference, formed all in one piece with the pan or basin, or it may be made of china, &c., and affixed to the top of the pan or basin, in any convenient way. This distributor is made of the shape of the inside of the top of the basin or pan, and is of the form of a portion of a pipe, the inner side thereof being cut away, so that there is a narrow space round the pan or basin, between the portion forming the waterway or pipe, and the basin. The water being let into the pan or basin by a valve, tap, &c., fills, or partially so, the tube or pipe, and passes out through the slot or space, between the basin and the pipe, and the stream thus distributed spreads over every portion of the pan or basin. *Patent abandoned.*

1993. J. Farra. *Improvements in wearing apparel called skirts or petticoats and frocks.* Dated July 10, 1863.

This relates to those skirts or petticoats and frocks, in which the lower part is formed by plaits on the fabric, which plaits are usually carried round the circumference horizontally, and consists in forming such plaits diagonally, in regular or irregular folds. Also in forming the plaited part in a piece separate from that above, and attaching it thereto. *Patent abandoned.*

1994. J. H. Johnson. *Improvements in braiding machines.* (A communication.) Dated July 10, 1863.

This relates to peculiar constructions and combinations of parts of braiding machines, whereby they are enabled to work at a greater speed than heretofore, and with greater precision and efficiency. According to this invention, it is proposed to employ a combination of a weight and a spring, for applying the requisite tension, and taking up the slack of the threads in the operation of braiding. This combination may be carried out in various ways. *Patent completed.*

1995. J. R. Hill. *An improved governor for the engines of steam vessels.* Dated July 11, 1863.

This invention is carried into effect as follows:—To the under side of the deck in the engine-room the inventor fixes a suitable frame, from which he suspends a common two-ball governor on pivots, so that it hangs freely, always remaining in a vertical position, uninfluenced by the varying position of the vessel. On the top of the governor-spindle there is a universal joint connecting it with another spindle, the upper end of which works in a bearing fixed to the ship. This latter spindle will be in a permanent position as regards the ship, and receives the motion for driving the governor at the upper end. Both these spindles are hollow, the lower one containing a rod, with flexible joints at the top, for transmitting motion from the balls to the lever of the throttle-valve. *Patent abandoned.*

1996. M. Cornall and E. Griffiths. *Improvements in doubling, twisting, and reeling threads and yarns of cotton and other fibrous materials.* Dated July 11, 1862.

Here the inventors place two or more cops of the thread or yarn to be doubled and twisted on skewers held in discs fixed to a spindle supported in rails or framings. The said spindle has a wharve fixed to it for giving it revolving motion by a band from a revolving drum. The yarns or threads from the cops pass through an eyelet central with the axis of the spindle, and the skewers radiate to the centre of the eyelet, from which the twisted yarns or threads proceed to the reel to be wound upon it, thereby performing the operation of doubling and twisting, and also winding or reeling at the same time. Any suitable number of spindles may be worked simultaneously. *Patent abandoned.*

1997. J. Maithman. *Improvements in machinery or apparatus for carding flax, tow, or other fibrous materials.* Dated July 11, 1862.

This consists in the application to carding engines of revolving rollers constructed of tin plate, or other suitable metal or material, which rollers are placed contiguous to the card rollers or workers, clearers or strippers, and lickers-in, in order to cause the fibres to be more firmly held or retained on the card rollers or workers, clearers or strippers, and lickers-in, thus preventing waste in fibre, and only allowing the dust and refuse to be thrown off. *Patent completed.*

1998. W. Ashton. *Certain improvements in machinery employed in the manufacture of braids and similar articles, parts of which improvements are also applicable to machinery used in spinning fibrous substances.* Dated July 11, 1862.

This relates, 1, To the regulation of the tension of the threads in binding machines, and consists in the use of apparatus in the space beneath the threads. The second part of the invention relates to those portions of braiding machines known as roses or carriers, being a description of toothed wheel, and also to the tubes employed to support the spindles, for which letters patent have been granted to the present patentee, dated the 22nd Feb., 1862 (No. 470), and consists in the application of a particular and peculiar material to the manufacture of such parts not hitherto so employed. A third part consists in the application and use of the aforesaid composition in the manufacture of "top rollers," or other rollers, "saddle hooks," and tubes for steadying spindles in spinning machinery. *Patent completed.*

1999. J. Orr. *Improvements in weaving piled fabrics, and in the machinery or apparatus connected therewith.* Dated July 11, 1862.

The patentee claims, 1, the system or mode of weaving piled fabrics, wherein the forming of the foundation fabric and the adjusting of the fur shoots are effected simultaneously, substantially as described. 2, The arranging of the catcher warps and other parts so that the normal position or position of longer duration of those warps is that of an open shed, substantially, and for the purposes, as described. 3, The introducing of the fur material in either power or hand looms by the improved means described. 4, The working of the catcher warps by an inverted needle frame, and the arranging of other parts in relation thereto to facilitate the introduction of the fur material, substantially as described. *Patent completed.*

2000. J. Miller. *Improvements in apparatus for steering ships and other vessels.* Dated July 11, 1863.

This apparatus consists of two racks, each of which carries a vane or blade, which blades are free to be protruded through the vessel's side on one side or the other by communicating up and down motion throuh a toothed wheel to the racks. The racks are so fitted with respect to the wheel that, while one is raised to bring its vane within the vessel, the other is lowered so as cause its vane to be protruded. The vanes may be set at right angles, or at any other desired angles, with the side of the vessel, and they may be fitted in the dead wood or in any other part of the hull. Instead of racks the vanes may be connected to a band or chain working over a drum or wheel, but the patentee prefers the racks as above described. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Oct. 28, 1862.

2899. J. Fletcher, sen., Leeds, and J. Fletcher, jun., Newcastle-on-Tyne. Improvements in machinery for shaping iron and other metals.

Dated Oct. 31, 1862.

2948. T. Gibson, Berwick-upon-Tweed, watchmaker, T. Hall, Gateshead, gentleman, and T. Davison, broker. Improvements in railway breaks.

Dated Nov. 7, 1862.

3014. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in decorticating grain and seeds. (A communication.)

Dated Dec. 2, 1862.

3229. J. and J. Craven, overlookers, and J. Robinson, manager, Clayton Mill, near Bradford, York. Improvements in looms for weaving.

Dated Dec. 22, 1862.

3418. M. Clark, Glasgow, Turkey red dyer. Improvements in treating waste liquors obtained when dyeing Turkey red colours.

Dated Dec. 23, 1862.

3424. C. A. F. Collette, Giberville, France, lace manufacturer. A new kind of lace.

Dated Dec. 31, 1862.

3698. F. Loret, Mecklin, Belgium, mechanical engineer. Improvements in constructing double weft-forks, applicable to every description of power looms.

Dated Jan. 2, 1863.

21. R. C. Ransome, Ipswich, agricultural engineer. Improvements in reaping machines. (A communication.)

Dated Jan. 7, 1863.

57. T. Storey, manufacturer. Improvements in compound waterproof and ornamental fabrics.

61. T. Aveling, Rochester, engineer. Improvements in the construction of traction engines.

Dated Jan. 8, 1863.

69. C. Allen, Basinghall-street, gentleman. Improvements in apparatus for signalling on railways by detonating or explosive signals.

Dated Jan. 9, 1863.

71. J. Punshon, Pemberton, near Wigan, engineer. Improved means or apparatus for preventing overwinding at collieries, and to provide extra breakage power to steam engines.

73. W. H. Tucker, 6, Southampton-street, Strand. Improvements in locks, and in the modes of connecting the knobs and spindles of the same.

75. C. E. Gray, Great Suffolk-street, Borough. Improvements in wringing machines.

77. M. Cartwright, Islington, engineer. Improvements in alarums for portable and stationary uses.

79. E. T. Hughes, 123, Chancery-lane. Improvements in machinery or apparatus for printing or staining woven fabrics, warps, paper, and other articles. (A communication.)

81. W. H. Moreland and J. Chappell, Loop Bridge Mill, near Belfast. Improvements in winding, warping, beaming, or dressing machines.

Dated Jan. 10, 1863.

85. W. Grove, Tenbury, Worcestershire. An improved apparatus applicable to the sawing and cutting of wood, or other light substances.

87. R. Lüthy, 2, Thavies-inn. Improvements in hydrostatic presses.

90. F. Fenton, Mappleton. Improvements in the manufacture of pulp for paper making and similar purposes.

91. E. Powers, Manchester, chemist, and G. Dale, Warrington, chemist. Improvements in the manufacture of caustic soda and potash, and carbonates, chromates, and stannates of the same alkalis.

Dated Jan. 12, 1863.

93. E. D. Chattaway, 1, New Broad-street, civil engineer. Improvements in railway signals.

97. W. Clark, 53, Chancery-lane, engineer. Improvements in the preparation of green colouring matter. (A communication.)

99. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the application of power designed for stationary and traction engines, propellers, and other machinery. (A communication.)

Dated Jan. 13, 1863.

101. J. B. Fenby, Worcester, gentleman. A new or improved instrument or apparatus to be attached to pianofortes, organs, and other similar keyed musical instruments, for printing the score of any music performed on the said instruments.

103. D. and J. Tannahill, Glasgow, engineers. Improvements in rivet-making machinery.

105. J. T. Stroud, lamp and chandelier manufacturer, Birmingham. Certain improvements in fixed and portable light, for domestic and other uses, applicable for burning gas and the mineral oils or spirits now so commonly used.

107. R. A Brooman, 166, Fleet-street, agent. Improvements in machinery for lifting bobbins off spindles in spinning machines, and in lubricating spindles. (A communication.)

108. W. Southwood, Birmingham, civil engineer. Improvements in machinery for manufacturing nails or brads.

109. M. Tildesley, Willenhall, Stafford, lock manufacturer. Improvements in the manufactnre of padlocks, and other locks and their keys.

111. L. Lescuyer, 2, Carrefour de l'Observatoire, Paris. Improvements in india-rubber overshoes or goloshes.

113. J. B. Rock, Pilton, near Barnstaple. Improvements in apparatus for saving life and property from fire and other danger in buildings and mines.

Dated Jan. 14, 1863.

115. J. Kidd, Cannon-row, Westminster, engineer. Improvements in apparatus for measuring the quantity of gas supplied to single burners, and increasing its illuminating power.

117. J. A. Schlumberger, Bâle, Switzerland, chemist. An improved process for manufacturing colours for dyeing and printing. (A communication.)

121. B. Burrows, Leicester. Improvements in looms used in weaving narrow fabrics.

123. E. Morewood, Stratford. Improvements in the manufacture of coated metallic sheets or plates and pieces, and in apparatus to be used therein.

125. T. Wilkinson, Scarborough, engineer. Improvements in the manufacture of tubular steam boilers.

126. W. Johnson, 166, Buchanan-street, Glasgow, civil engineer. Improvements in the manufacture of chlorine and bleaching powder, carbonate of soda, and soda ash and sulphate of iron. (A communication.)

Dated Jan. 15, 1863.

129. E. Howes, Birmingham, lamp manufacturer. Improvements in railway, ship, and other lamps.

133. G. Graham, manager, and J. M'Leod, Renton, engineer. Improvements in apparatus to be used in Turkey-red dyeing.

135. L. P. Josse, Paris, France, gentleman. An improved apparatus for cleansing wheat or other grain or seeds.

139. J. W. Child, Halifax, engineer. Improvements in means or apparatus employed in spinning and weaving.

141. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in microscopes. (A communication.)

142. D. F. Leblanc, 3, Percy-street, Bedford-square. An improved level indicator or liquid gauge. (A communication.)

143. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in looms or machinery for the manufacture of lace and other fabrics. (A communication.)

Dated Jan. 16, 1863.

145. L. Verdure, Tournai, Belgium, spinner. Improved slubs or rovings (in flax, hemp, and other filamentous materials), produced by the slubbing frame, and destined for fine spinning, as also for improved apparatus employed therein.

147. M. Moeglen, Cernay, France, mechanist. Machinery for printing several colours in succession on the same surface.

148. E. Loysel, Cannon-street, civil engineer. Improved apparatus for preserving valuable property, documents, and letters, in cases of shipwreck.

Dated Jan. 17, 1863.

149. W. Shorrock, Tockholes, near Blackburn, manager. Certain improvements in power-looms for weaving.

151. J. Lightfoot, Accrington, chemist. Improvements in printing and dyeing textile fabrics and yarns.

152. I. Ashe, Birkenhead, bachelor of medicine. Improvements in apparatus for sea-sickness.

153. J. Combe, Leeds, engineer. Improvements in machinery for spreading, drawing, and carding flax and other fibrous substances.

154. G. Haycraft, 23, Lombard-street. Improvements in powder flasks.

Dated Jan. 19, 1863.

157. E. Sabel, Moorgate-street, gentleman. Improvements in the manufacture of artificial stone. (A communication.)

159. J. Laurie, Manchester, agricultural implement maker. Improvements in apparatus for churning milk and mixing liquid compounds.

160. Sir W. O'S. Brooke, 107, Avenue des Champs Elysees, Paris. Improvements in the manufacture of insulators for electric telegraphs.

161. H. Rushton, Northampton-road, Clerkenwell. Improvements in machinery for plaiting cotton, thread, or other fibrous materials over steels for crinolines, and in the mode of securing the plaiting to prevent it slipping thereon.

162. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of sulphate of soda for conversion into soda and other uses. (A communication.)

163. W. H. Harrison, Haverfordwest. Improvements in covering wire and other iron articles for the purpose of protecting them from oxidation, and in the mode or method employed therein.

Dated Jan. 20, 1863.

167. J. Mosheimer, Dolgelly, Wales, gentleman. Improvements in machinery for crushing and grinding quartz and other substances.

168. J. Bell, foreman, and J. Speight, fitter, Phœnix Iron Works, Jersey-street, Manchester. Certain improvements in the construction of carding engines.

169. W. Mawson and J. Whitehead, Calverley, near Leeds. Improved hydraulic machinery for raising water in mines, wells, and other places.

170. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in the manufacture of clocks. (A communication.)

172. M. Henry, 84, Fleet-street. Improvements in apparatus for retarding and stopping railway carriages. (A communication.)

175. H. Hughes, Homerton, engineer, and J. Sanders, Nottingham, lace manufacturer. Improvements in machinery and apparatus for the manufacture of trimmings and cap fronts.

176. S. Blackwell, 259, Oxford-street, saddler. Improvements in apparatus for applying water or other fluid to the legs and other parts of horses and other animals.

Dated Jan. 21, 1863.

178. A. Phillips, Glasgow, gentleman. Improvements in looms for weaving figured fabrics.

180. F. A. Busch, Briton Ferry, South Wales. Improvements in the manufacture of metallic vessels or receptacles for containing liquids or substances.

182. H. B. Barlow, Manchester. Certain improvements in jacquard machines. (A communication.)

184. A. Boubée, Paris, manufacturer. Improvements in apparatus for casting or moulding articles in glass, and in imitation of precious stones or marbles.

186. W. Clark, 53, Chancery-lane, engineer. Improvements in desiccating and in preserving matters from decay. (A communication.)

190. A. Pennington, 1, Rectory Villas, West Hackney. Improvements in apparatus for beating mats, rugs, and other such like articles.

Dated Jan. 22, 1863.

194. W. Harrison, Blackburn, machine maker, and B. Croasdale, Witton, near Blackburn, overlooker. Certain improvements in looms for weaving.

196. J. Grant, Albion-place, Maidstone, farmer. Improvements in the construction of sidings and loop-lines for railways or tramways, whether portable or otherwise.

200. W. and J. Blackwood, Craigton, bleachers. Improvements in machinery for drying yarns or threads.

202. N. Wood, Hetton Hall, coal owner, and J. Stockley, Newcastle-on-Tyne, engineer. Improvements in apparatus for grinding, smoothing, and polishing plate glass.

204. C. Lungley, Deptford, ship-builder. Improvements in means for facilitating the repairs of ships and other structures.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, Feb: 3.

2588. J. Long. Cleansing and scraping streets.

2595. W. Dobson. Producing various colours on lace.

2596. J. J. N. Micas. Railway brake.

2601. J. Farran. Looms.

2618. W. Lea. Hinges.

2619. A. Potter. Electro-magnetic engines.

2625. J. J. Bates. Window sash fastener and guard.

2629. W. E. Gedge. Construction of leaden window sashes, casements, or glazed coverings on partitions. (A communication).

2635. J. C. P. Bauchard. A twice-transversal kneading trough.

2643. H. Hirsch. Showing combinations of colour.

2647. J. Addison. Moorings or apparatus for securing articles.

2648. R. A. Brooman. Saddle trees and collars.

2649. J. H. Johnson. Shells for war purposes. (A communication.)

2657. P. G. Van der Byl. A power conserver brake for utilizing the power expended in stopping or retarding machinery. (A communication.)

2691. W. Taylor. Preparing fibrous materials.

2694. J. Bradbury. Carding engines.

2695. D. Lowe. Manufacture of door bolts and latches.

2701. A. V. Newton. Apparatus for drying grain. (A communication.)

2703. J. Heap. Screw stocks and dies.

2738. D. S. Sutherland. Constructing beams, girders, bridges, and viaducts.

2849. T. Greenwood. Preparing fibrous substances to be spun.

2870. P. S. Devlan. Manufacture of bearings, steps, axle boxes, and other surfaces and appliances, or articles subjected to friction.

2880. T. G. Ghislin. Treatment and utilization of certain foreign plants.

2997. A. V. Newton. Obtaining printing surfaces. (A communication.)

3151. R. and W. Hawthorn. Pump valves.

3193. W. Clark. Permanent way. (A communication.)

3240. H. Wilde. Magneto-electric telegraphs.

3423. R. A. Brooman. Improved colouring matter or dye. (A communication).

37. H. Bessemer. Construction and mode of working apparatus to be employed in pressing, moulding, shaping, embossing, crushing, shearing, and cutting metallic and other substances.

92. D. Dawson. Manufacturing magenta colour or dye.

114. H. Bessemer. Manufacture and treatment of malleable iron and steel.

119. G. T. Bousfield. Rolling, grinding, and cutting files. (A communication.)

121. B. Burrows. Weaving narrow fabrics.

123. E. Morewood. Coated metallic sheets or plates and pieces.

128. W. Hulse and C. L. Haines. Manufacture of taper metallic tubes.

151. J. Lightfoot. Printing and dyeing fabrics and yarns.

155. G. T. Bousfield. Hot air engines. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Jan. 28, 1863.

2173. C. Bedells.
2181. G. A. Biddell.
2182. J. C. Onions.
2183. R. and D. Nurse.
2184. J. E. Marsh.
2185. C. H. Plevins and H. Rider.
2187. T. G. Webb.
2188. T. Onion.
2190. J. Gray.
2197. J. Higgin.
2202. A. Priestley.
2218. R. W. Ralph.
2232. J. J. H. Gebhardt.
2301. J. Carter and J. Maher.
2398. J. Davis.
2425. J. Mosheimer.
2457. W. E. Newton.
2551. W. E. Newton.
2638. R. Griffiths.
2981. J. Place.

Sealed Jan. 30, 1863.

2194. A. and E. M. Denny.
2198. J. Townsend.
2221. F. M. Jennings.
2283. G. Welch.
2579. P. L. Forestier.
2904. C. S. Duncan.
3250. J. Grant.

Sealed Feb. 3, 1863.

2199. W. Clark.
2203. W. W. Burdon.
2206. W. G. Valentin and F. Levick.
2208. J. H. Johnson.
2212. F. H. M. C. D. C. de F. de Lacombe.
2214. R. A. Brooman.
2215. R. A. Brooman.
2219. E. Hall.
2226. E. Humphreys.
2227. J. Tatham.
2236. G. T. Bousfield.
2247. J. Combe and J. H. Smalpage.
2251. W. Macnab.
2275. L. D. Verstraet and E. M. Olivier.
2317. J. Briere.
2324. W. J. Hoyle and J. Proven.
2347. R. Harrington.
2360. W. E. Newton.
2365. G. Davies.
2371. G. Davies.
2491. G. Ritchie.
2559. W. and J. Todd.
2609. W. Upfill and W. Asbury.
2978. J. McKean and T. Greenhall.
3247. A. F. Eden.
3331. C. Hancock and S. W. Silver.
3337. J. Brown.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

208. R. Sykes and P. Sykes.
206. C. F. Varley.
223. J. H. Johnson.
226. J. Jeffreys.
229. E. Langrn.
238. E. Brooks and H. Waters.
266. M. A. F. Mennons.
242. G. A. Cator.
250. W. E. Newton.
284. T. Blackburn and M. Knowles.
285. R. Adams.
274. T. Routledge.
323. H. C. Jennings.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

255. J. Gretton
390. E. Deiss.

The *Daily News* of May 29th, in its description of Benson's Great Clock, says: "The entire finish is of the highest cast." Benson's new Show Rooms contain clocks designed by the first artists of the day, and include clocks for the drawing room, dining room, bed room, library, hall, staircase, bracket, carriage, church, turret, railways, warehouse, counting house, with musical, astronomical, and every description of clock, from the plainest to the highest quality of which the art is at present capable. Church and turret clocks specially estimated for. Benson's illustrated pamphlet on clocks and watches (free by post for two stamps), contains a short history of clock and watch-making, with descriptions and prices; it acts as a guide in the purchase of a clock or watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any part of the world to select a clock. J. W. Benson received a Prize Medal and honourable mention. 33 and 34, Ludgate-hill, London. Established 1749.—[Advt.]

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, FEBRUARY 13, 1863.

THE PETITION OF RIGHT.—CLARE *v.* THE QUEEN.

The recent trial upon a Petition of Right, in the case of Clare *v.* the Queen, assumes importance, because it furnishes the opponents of the principle of granting exclusive rights to inventors with fresh standing ground.

We again hear complaints about the inconvenience of "the system of squatting upon the open heath, where all men ought to be able to range free." And regarding this case as a new instance of the mischievous tendencies of the present system of patents, the *Times* recommends immediate legislation for the purpose of sweeping away the whole system. While we dissent from this view of the case, we certainly are not prepared to establish a complete defence of the new Patent Law. The present case is indeed a striking example of its shortcomings.

The patent in question was granted on the 5th of September, 1853, for "improvements in the construction of iron houses, vessels, &c." If we are to believe the evidence that was given on the part of the Crown, it bears its legal condemnation on its face. Instead of confining himself in the complete specification within the limits described in the provisional, the inventor has introduced a large number of subjects into the former which are not referred to in the latter.

Another of the conditions of patent-right is that the inventor shall communicate fully to the public, not only the nature of his invention, but also its extent and details, so that the public may be able to understand and use it when the patent-right has expired.

But in this case, both the specification and the drawings were so obscure, that the main difficulty in the trial lay in discovering what it was that the petitioner claimed to have invented.

It was contended further, on the part of the Crown, that what appeared to be substantial parts of the petitioner's invention were contained in the previous patents of Dickenson, Guppy, Boydell, and Fairbairn. It was therefore open to the Crown to rest the defence upon any of these grounds, without attempting to prove that the "Warrior" did not contain any of the supposed inventions. But, while evidence was given on all these points, and they were submitted to the jury as distinct questions by the Lord Chief Justice, it was thought better to endeavour to obtain from the jury the more satisfactory verdict that the supposed inventions of Mr. Clare had not been used in the construction of the iron-cased ships of war.

This verdict the jury did not hesitate to give; and they added that, while they were of opinion that the complete specification did contain matters which were not included in the provisional, they desired to be excused from giving answers on the other points, affecting the validity of the patent.

The petition recited five particulars, in which the patent had been infringed by the Crown in the construction of the "Warrior," but during the progress of the case the petitioner's counsel dropped these and adopted two others, which promised to be more defensible. The claim was finally stated by the counsel to be "a combination of vertical and longitudinal framing, and a mode of fastening iron plates to it."

It was alleged, on the part of the petitioner, that previously to 1853 ships had been built without any longitudinal framing, and that whereas the framework should be sufficiently strong to hold firmly together without the aid of the plating; ships, as ordinarily built, would fall to pieces if the plating were taken off. The loss of the "Birkenhead," in 1847, had directed the attention of Mr. Clare to this defect in naval construction. He had carefully studied the matter; and, although not a professional shipbuilder, had devised the mode of remedying the defect, which he had embodied in his patent. This remedy was said to be the introduction of longitudinal frames crossing the ordinary vertical frames.

As it was, of course, undeniable that the "Warrior" had such a system of frames, it was contended on the part of the Crown, first, that the petitioner's specification did not describe or show, as was alleged, any longitudinal and vertical framework, independently of the plates; and, secondly, that if it were shown, it was known and used long before the date of the patent. Notwithstanding the obscurity of the specification, the jury decided that such framework was not described or shown, and it was on this fact that the question mainly turned.

The construction which the patentee seems to us to have described in his specification, is as follows:—He proposes to make all his vertical frames of T-iron, and to place them about eight feet apart. He then introduces a number of horizontal bars between the vertical bars, made either of flat plate or of T-iron, and disposed in rows about three feet apart. These short horizontal pieces are not fastened to the vertical frames until the plates are brought on, when some of the rivets in the plate fastening will pass through and connect the ends of the horizontal bars and the flanges of the vertical bars. Each plate is then made the same length as the interval between the vertical frames, and the same breadth as the distance between the horizontal frames, so that the *joints* of the plates are covered by the horizontal bars, to which they are rivetted by a single row of rivets in each edge, and the *butts* of the plates are covered by the vertical frames to which they are similarly rivetted. Thus, at intervals of eight feet, there is a double row of rivets in the same line from the keel to the gunwale—a system of construction which would prove fatal to any floating structure. In iron shipbuilding, one of the fundamental principles is, that the butts of the plates should not lie in one line, but should be disposed irregularly.

Some seventeen or eighteen years ago, a vessel was built on the Thames, by Mr. Fairbairn, under the patent referred to in this case, which was similar to Mr. Clare's in this respect, that the butts or ends of the plates were disposed in a regular line, supported behind by vertical frames of T-iron. It was found impossible to keep her water-tight, and after being in the possession of the parties for whom she was built about five years, she was sold for less than one-twentieth of the money which she cost.

It will be evident, from what we have said, that the petitioner had no sort of claim for infringement of patent rights, either legally or morally. There is, moreover, reason to believe that he was not ignorant of this. Evidence was given on the trial, that before the patent was taken out he had been advised professionally that the matters it contained were neither new nor useful, and we have good reason to believe that Sir Charles Fox is not the only professional man who has given Mr. Clare wise counsel in this matter. Good advice has, however, been thrown away upon him, and we have to lament that the public time and money should have been wasted in such a vexatious case.

But the petitioner not only claimed compensation for the use of his patents; he sued also for commission as architect for designs and plans furnished by him at the request of the Admiralty. The commission claimed was five per cent. upon the cost of all the iron ships built by the Admiralty. This would amount, as the Attorney-General showed, to at least £100,000 per year, the money already due to Mr. Clare under such an arrangement being £500,000. Mr. Clare considered that, when this was paid, the country would owe him a large debt of gratitude. In support of this part of the case there was not the shadow of evidence. Like many other inventors he had been told by the Admiralty, in answer to his numerous letters directing attention to his inventions, that if he would forward any suggestions with regard to the construction of iron ships, they would be considered. Such suggestions as he sent appear to have been in every case formally rejected. There was no evidence that any design for a ship had been sent in by him under any circumstances; or, indeed, that he was able to make one. Permission was refused him to furnish drawings at the time when the assistance of private shipbuilders was invited by the Admiralty in designing the "Warrior"—assistance which, by the way, was freely given by them and given gratuitously. The Lord Chief Justice said that in the whole course of his experience he had never heard of a claim so wild and so extravagant as this. We have not patience to write more upon this case. Such patentees as this are a social nuisance, of which we trust we shall be able to rid ourselves, while we continue to afford protection to the rights of the legitimate inventor.

WHEEL CUTTING MACHINES.

It is scarcely necessary to urge upon any practical mechanic the great value of a good wheel-cutting machine. It is well-known that this description of special tool was amongst the first machines that made their appearance in English engineers workshops. Messrs. Fox, of Derby, appear to have been the originators in England of an engineer's tool for cutting and dividing the teeth of wheels. Brass wheels—and wooden wheel patterns of a smaller diameter than six inches, and of fine pitches, have their rims generally cast to the depth of their teeth, which are divided and cut out of the casting by the machine. Circular, or rose-cutters, are often formed in the same way.

If a cast-iron toothed wheel be cast perfectly true, it is, of course, better to leave it untrimmed. To take the skin off a casting always reduces its strength, but it also diminishes the duration of the teeth of a wheel. The skin on a casting is somewhat like the skin produced by case hardening a piece of wrought iron. For many years Mr. Whitworth has turned out the change wheels of his lathes, &c., without any trimming. Larger wheels, however, are often trimmed up, as it is not so easy to cast a large toothed wheel quite true. The wooden cogs of mortice wheels are also generally shaped by hand, and this is more especially the case with the cogs of bevel gearing. Cast-iron wheels intended to work with mortice wheels, generally have their teeth trimmed up by hand. This is a costly and tedious operation, but its necessity is apparent. The wooden cogs of a mortice wheel would be speedily worn away by the rough surface of cast-iron teeth.

Steel circular cutters of the exact shape of the tooth are generally used for cutting spur wheels. It will be seen at once that it would be impossible to cut a bevel tooth by means of a circular cutter, without setting the cutter at an angle. The teeth of a bevel wheel of course advance and recede, both as to depth and breadth. Even when a correct circular cutter is used, the wheel is not completely finished by this process; it must be trimmed up by hand-filing. It is scarcely possible to get a correct bevel wheel by means of a circular cutter.

In our number for October 24th, 1862, p. 253, under the heading of "Machine-tool Substitutes for the File" we alluded at some length to the subject of circular cutters, and we there proposed to make a circular cutter for iron upon the same plan as the cutters used in "Biddell's patent oat-mills." It is evident that the circular cutters used for wheel cutting machines might be made in the same way. Circular cutters, formed of one piece of steel, often spring while being hardened, and are also very liable to warp while undergoing this latter operation. When in use, should any teeth be broken off, the whole cutter must be turned up, softened down, and recut. There is also a difficulty in sharpening the edges of the teeth, when the cutter gets worn. Mr. James Nasmyth, of Patricrift, some thirty years ago, made circular cutters out of a number of separate knives, in the following manner:—

He built up the circular cutter out of a number of separate steel cutters, the inside of each cutter being of a wedge shape, and the whole number required were arranged in radii from the centre of the disc. A wrought-iron ring was shrunk on the circular bundle of cutters, so that it could be turned up in the lathe, just as if the cutter were in one solid piece. One side of the cutters is first turned up, and is then fitted into the chuck of the circular shaping or wheel cutting machine. The chuck is furnished with a set-screw, and this screw is caused to press upon one of the separate cutters, which thus acts as a wedge between the other cutters. The wrought-iron ring is then knocked off, and the other part of the circular cutter is turned up in the lathes, so that all the separate knives or cutters are of the same shape.

On slackening the set screw, the separate knives can be easily taken out of the chuck, and filed up to the required shape. On being properly hardened, the knives are replaced in the chuck. They are then screwed up by the set screw, and the whole circular cutter is thus ready for use. Before the modern improvements in moulding, enabling us to cast wheels with greater precision, wheel-cutting and dividing machines seem to have been in greater demand than at present. We have seen, in an old German periodical for 1813, a design for forming a circular cutter for toothed wheels, upon a plan somewhat similar to that of Mr. Nasmyth. The German design was avowedly suggested by Mr. Nasmyth's cutter. A circular cutter for the teeth of wheels must, of course, cut on three sides, taking up the sides and bottoms of the teeth. This kind of circular cutter must also be fixed on a mandrel, and requires to take the shape of a wheel. It is thus impossible to fix such a cutter on the chuck of a lathe; it must be independent of all such support. The way described was the following:—The separate cutters were filed up to a wedge shape, and arranged in radii together; a wrought iron ring being then shrunk on the whole. This steel disc was then placed on a lathe, and the centre bored out to the size of the spindle upon which it was to be fixed. The disc was then fixed on a mandrel, properly turned up to the required shape, and a circular groove was then formed some distance from the centre. This groove was made of a conical or beveled shape, and a ring was fitted into this groove. The ring thus keeps the separate cutters together, when the outside ring was taken off. If this inside ring be once tightly driven into the groove, the outside ring can then be taken off. The steel disc or cutter is then placed on a mandrel, and turned up in a lathe to the required shape. There is a boss on the spindle of the circular cutter, and a nut is screwed up against the other side. The separate cutters are thus kept from being pressed out. These independent cutters can also be separately taken out, sharpened, and hardened, just like Mr. Nasmyth's cutters.

In our volume for 1849 will be found a self-acting method, proposed by a student of St. John's, Cambridge, for cutting the teeth of the drivers of pin wheels or trundles. We do not know whether this plan has ever been carried out.

There were three machines in the International Exhibition for cutting the teeth of wheels; two of these used circular cutters. One was exhibited by Mr. Whitworth, of Manchester, and figured in the western annex. The second machine was sent by Cook and Sons; it was intended more especially for horological wheels, and was on the same general principle as Mr. Whitworth's machine. The machine exhibited in the International Exhibition by Mr. Whitworth, was intended to cut spur, bevel, and screw wheels; in metal or wood. It could cut wheels up to ten feet in diameter. This machine consisted of a long bed, similar to a lathe bed. A circular cutter was used, which was intended to be set at an angle when bevel wheels were required. The circular cutter was on a vertical spindle, working in an adjustable head-stock. The speed of this cutter could be varied to suit wood or metal. The wheel to be operated upon was fixed on the end of a mandrel fitted in a sliding bracket. There was an ordinary dividing apparatus for pitching the teeth. This machine is amongst the best tools of Mr. Whitworth. It no doubt, does its work very efficiently, with respect to spur and screw wheels, but it is subject to the objections we have previously alluded to; when speaking of cutting out bevel wheels by means of a circular cutter. The third wheel-cutting machine was exhibited by John Hunt and Co., of Bow. We have also heard of this firm in connection with anti-friction metal bearings. It was a special tool for dividing and cutting bevel gearing. Although in an out of the way corner, it excited some attention, from its exquisite ingenuity, and as an example of right adaptation of means to an end. The attendant asserted that the machine could pitch and trim more wheels in one day than could be achieved in a week by a good millwright. The apparatus consists, essentially, of a shaping machine with a reciprocating tool. This tool has a stroke of about three inches. The slide is made upon the plan first adopted by Mr. Nasmyth, of Patricrift. The tool box slides on a top and bottom V, and is therefore less subject to any side deviation through wear. In front of the tool holder are two fixed bearings, carrying a cross shaft, through the centre of which is a socket holding a mandrel. On the bottom end of this mandrel is fixed the wheel or pattern to be operated upon. On the top end is adjusted the dividing plate or apparatus. This mandrel has a motion in a vertical plane, and another motion horizontally; out of a composition of these two movements the varying depth and breadth of the bevel teeth are produced. The vertical motion is obtained by means of a worm working in a toothed segment. The feed motion is communicated by a cam on the driving shaft, working into a ratchet wheel. This wheel in its turn works the worm and segment. The depth of tooth for the bevel gearing is thus obtained. The form of the teeth is produced by means of a lever attached to the mandrel on which the work is fixed. In the other end of the lever is fixed the shape of the tooth upon a somewhat increased scale. This templet acts against a steel straight edge on a line with the tool. The vertical motion acting upon this lever works the tooth down, and thus transmits the motion from the templet, to the tooth of the wheel being produced. The templet is kept against the steel straight edge by means of a spring. There is an ingenious spring and detent motion, throwing the vertical movement out of gear when the tool reaches the bottom of the tooth. The dividing plate, to which we alluded before, is set by hand when each tooth is finished, and it is kept in position by a lever and point. This lever is adjustable, in order to regulate the thickness of the teeth. The pitch is given by the holes in the plate. After cutting one side of the teeth, round the whole circumference of the wheel, a left-handed cutter is substituted for the previous tool, which we will suppose to have been right-handed. The templet or shaper is also changed to the other side. The machine is then put in motion to complete the shape of the teeth

We hope next week to be able to illustrate this interesting machine.

In our volume 52, for 1850, p. 97, will be found an account (extracted from the *Franklin Journal*) of "a machine for cutting teeth for beveled gear" then patented in America by George H. Corliss. The machine is not illustrated, but, as far as can be gathered from the description, its principle is slightly similar to the machine of Messrs. Hunt and Co. "A reciprocating cutter that moves in a slide is used, which cutter vibrates on an axis that coincides, or nearly so, with the apex of a cone representing the bevel of the wheel to be cut, and by which vibration the depth of the cut is determined." It is thus seen that the *reciprocating cutter* is adjustable.

The *work* is adjustable in Messrs. Hunt and Co.'s arrangement.

CALIFORNIA AND GOLD.

The enormous and continually increasing supply of the precious metals is one of the most momentous occurrences of modern times. Will the quantities produced ever reach a "point of saturation," to borrow a chemical term? Will the wants of luxury or the requirements of an extending monetary circulation keep up the value of gold and silver? Or are these metals condemned to depreciation by increasing abundance, and by cheapened production? These problems are still agitating the political economists of the day. Some believe that gold is lowering in value by the excessive supply. Other political economists look upon the influx of the precious metal as an immense benefit; believing that gold is the great motive power of commerce and industry,

The Emperor of the French probably looks upon the abundant supply of gold, and its increasing influence on his times, as important questions with which he may have to deal Accordingly, about two years ago, he commis sioned a French engineer to explore the gold regions of California, and to report to him thereon.

The Emperor's orders have been followed by Monsieur Laur, who has published an interesting summary of the gold question, as far as California is concerned, in the second number, for 1863, of the *Revue des Deux Mondes.* We will translate, for the benefit of our readers, some portion of this interesting paper of M. Laur, regretting that we have not space enough for his picturesque geographical account of California. The Sierra-Nevada, in Upper California, is the principal gold region; it is described as a mountain with a literal *cloak of gold.* Upper California is also plentifully supplied with wood and water, the two great requirements of gold mining, and without which the richest gold field would be unproductive. The gold being once discovered, this country, so favoured by nature, only required an industrious population to fully develop its immense resources. Such a population was supplied from the United States, and the North Americans settled down in the country with the enterprizing spirit of their free race. The new land was quickly explored. Its gold flowed over to the Old World with prodigious celerity. The first gold fields were of unheard-of wealth; they were worked with feverish haste, and the production was enormous. The richer fields are now worked out, and the difficulties of extracting the gold have increased. The powers and genius of the workers, however, have not lagged behind. In proportion as the difficulties increased, more powerful means were employed. In most other countries gold digging is a painful toil, at which the gold-washer consumes his strength in working rude washing apparatus. In California, gold mining is now a splendid industry, and it forms a worthy rival to the boldest metallurgical enterprises of the Old World. In order to understand the various mechanical means adopted in California for extracting gold, it will be necessary to give some account of the different forms in which the metal is found.

Science has completely recognised that the gold of California is of more recent formation than the rocks containing the precious metal. Long after the quartz rocks had been formed, one of these geological commotions that have so often shaken our globe took place. Great portions of the Sierra-Nevada hills were raised up at this epoch. The whole mass of our planet was in travail, its solid crust was opened up, and gave passage to some of the fused matter still seething in the interior. These masses surged up in the form of mountains. Currents of sulphur, iron, gold, and other metallic substances, impelled by the force of steam, flowed out of the subterranean furnace. These metallic emanations flooded the country, They oozed into the upper strata of certain rocks, and impregnated them with gold. They entered the thousand fractures caused by the up-heaving of the ground, and were condensed into veins of metal. Such is supposed to be the origin of the *primary deposits of gold.*

These volcanic phenomena probably took place while the continent was covered with seas of water in violent agitation. Further changes consequently took place, and the surface deposits of gold were swept away. The rocks, the gold veins, were dismantled and crushed up, and layers of sand, gravel, and clay, mingled with gold, were spread pell-mell over the country. The gold remained unchanged in the midst of the universal wreck, and separated itself from the gravel formed by the diluvial action. In the lower strata the gold arranged itself into layers, thus forming strata often richer than those of the *primary deposits.* We can distinguish these layers by the name of *ancient auriferous alluvia.*

The surface of the country took its definitive shape after this last geological revolution of the diluvial period. The modern epoch then began, an equilibrium was established between the elements, and everything was given up to repose. New and more gradual influences, however, still continued to affect changes in the arrangement of the gold. The atmosphere disintegrated the rocks, the waters ate away the soil, carrying away the sand, while they left the heavier gold behind. Under these ever-renewing influences, the gold got concentrated in the direction of the main currents of water. This washing action thus formed the *contemporaneous gold alluvia.* The action of the waters was comparatively slight on the hard rocks of quartz, encasing the gold in its *primary formation,* but their action was much more powerful on the *ancient diluvial deposits.* The minerals were thus crushed and washed ready for extracting. These influences extended over many centuries before the gold discovery. The prodigious riches that California suddenly put into circulation were thus found ready formed in the river beds of the country.

It will now be seen that the gold was found in three distinct kinds of deposits. These three sorts varied greatly as regards the difficulty of extracting the gold. The *primary formations* kept the gold stored up in hard and tenacious rocks, requiring to be excavated, crushed, pulverised, and last of all carefully washed, in order to extract the gold dust. The second state in which the gold was found (the "*ancient alluvia*") freely gave up the gold in the midst of gravely soil. Nature had taken upon herself to crush and pulverise the rocks; the washing only remained to be done. The mineral was almost completely elaborated in the "*modern* or *contemporaneous alluvia.*" The grains of the metal shone with their unchangeable lustre in the sands of the rivers, and only wanted picking up. The first Californian gold was found in one of these rivers.

The gains of the gold-diggers were at first perfectly fabulous. The American River produced 5,000,000f. worth of gold within less than two months. This was in 1848. After 1852, however, there was no more virgin soil left in the streams of Nevada. It became necessary to excavate the sands of dried up ravines, to carry away the mineral to be washed, or to conduct the water to the spot itself, by means of expensive canals. The miners found themselves obliged to turn back the water courses of the rivers, to form costly excavations, and to erect expensive machinery for pumping out the water. Nature begun to battle for her treasures, and day by day the miner found his profits diminishing. According to M. Laur, the miner's gains per diem, on an average, 132f. in 1848 and 1849, 95f. in 1850, 64f. in 1851; fell to 25f. in 1853, to 15f. in 1856, and to 13f. in 1858, and were then still so diminishing that the river diggings were entirely abandoned by the white race of gold-miners. The Chinese took their place; and these sober and skilful workers still wash the refuse of their predecessors, in some places perhaps for the tenth time. These Chinese diggers only earn some 3f. or 4f. a day, and even these poor gains are diminishing, so that the river diggings, formerly so abundant, may now be looked upon as almost entirely exhausted.

Calafornia would have shone with but a transient brightness if she had only these river *placers.* There remained, however, the *alluvial deposits of ancient origin,* the veins and the auriferous rocks; the main reservoirs of the precious metal. The questions were, how to work these *dry, hilly, diggings* without water, and how to crush the veins of hard quartz?

The spirit of invention was then called in to aid the spirit of adventure. In the midst of the confused mass of men, private interest organized a regular system of labour. The isolated miner became a rare exception. On all sides associations were formed, and each individual chose the task the most to his taste. Some made the roads, built the bridges, and erected mills; others excavated canals, and distributed to the miners, at so much per measure, the water required for washing the gold. A smaller number excavated the veins of quartz, and imported, at great expense, gold-crushing machinery for breaking up the ore.

The first miner's implement was a large dish of tin plate, or simply of wood. This dish was filled with earth, and shaken up in water, so that the sand was thrown off, while the heavier gold remained at the bottom of the plate. The miner, with this dish, could wash at the most 400 kilogrammes of earth (about 7½ cwt.) per day. In those times, however, he found the river diggings to yield 400 or 500 francs worth of gold per cubic metre. The gold-digger could thus earn 125 to 130 francs per diem. After the dish there came the "*rocker.*" The "rocker" is a small oblong box without a cover, and open at one of the smaller ends. The bottom of the rocker is covered with a piece of coarse cloth. The box is placed on a slope towards the open end, and it can be made to rock to and fro like a child's cradle. A grating is placed on the open top of the box. The earth containing gold dust is shovelled on to the grating. While the apparatus is being rocked to and fro, it is supplied with a stream of water. The heavier gravel remains on the grating, and the earthy matters and the sand pass through, fall down, and roll out, while the gold is kept back by the coarse cloth at the bottom. A miner could wash 1,500 kilogrammes (23½ cwt.) of sand per day with the rocker. This produced four times as much as with the dish, but the soil had become about six times poorer, and the gold-digger only earned 85 francs per day. The "*long-tom*" was then invented, with which the miner, by using a quick current of water, could wash 6,000 kilogrammes (114 cwt.) of sand per day. This was a great advance on the dish; but the progress of invention did not stop here, and the "*sluice*" method of washing was invented. The invention of the "*sluice*" marks a complete revolution in the working of gold.

The *sluice* is a canal formed of three planks, one for the bottom and two for the sides. This canal is narrow, being about 0·30 metres (about one foot) broad, but it is very long, as its length must be not less than 100 metres (328 ft.), and it sometimes measures more than 1,000 metres (3,280 ft.)

The bottom is paved with rough, knotty wood. It is set on an incline, varying with the nature of the soils to be washed, and it is traversed by a plentiful and violent current of water. Five or six diggers ceaselessly shovel in the auriferous soil. The water carries away the sand and stones; but the gold, separating itself from the muddy current, gains the bottom, where it adheres, being seized upon by the mercury there present. The gold is taken out of the sluice once every week.

The invention of the sluice was of itself a fortune for the miners. Instead of only washing 400 kilogrammes (about 7½ cwt.), as with the dish, they could wash 18,000 kilogrammes (342 cwt.); and they could therefore work, with profit soils 45 times poorer. Furnished with this new apparatus, mining adventurers abandoned the rivers, and took up what are called the *dry diggings*, which are situated in the interior of the country.

The first gold deposits worked by means of the *sluice* were the formations belonging to the last epoch of the diluvian period. These formations were the easiest to work, and they consisted of immense heaps of sand and gravel, in which the gold lay bared to the eye, and was easily accessible. These shingle heaps are not much raised above the water courses, so that it was easy to convey the water for extracting the metal. All these gravel heaps contain more or less gold, but the metal is disseminated in a very irregular manner. Some portions contain immense riches, while others are absolutely barren. It often happens that the keeper of a store makes his fortune while the miners can scarcely earn enough to provide themselves with food. The irregularity in the results, renders it very difficult to ascertain the average wealth of this class of gold deposits. It is scarcely possible to state precisely the sums of gold contained in this kind of formation. It will be best to take the average of the results obtained from the present workings. Monsieur Laur estimates this at four or five francs worth of gold per cubic metre. He gives the balance-sheet of an ordinary gold digging enterprise of this description.

Eight miners, with a capital of 4,000 francs, can undertake one of these *sluice* diggings. They would have to build their own house near the spot chosen. This wooden house would cost to build and roughly furnish :—

A sum of about . . .	1,500	francs.
The complete erection of a good *sluice* would cost	1,200	,,
Mercury and tools . .	550	,,
Food for the eight men	750	,,
The miners could then wash 100 tons or 67 cubic metres of gravel per day, which, at 5 francs worth of gold per cubic metre, would give	335	,,

The expenses per diem would be :—

Water bought from the canal companies . . .	25 f.	90 c.
Provisions (3 dols per man and per working week) . .	21	60
Mercury, candles, and tools	10	36
Total expenses per diem	57 f.	86 c.

This being deducted from the 355 francs worth of gold per day, gives a clear profit to the eight men of 277 francs 14 cents. So that each man appears to earn 34 fr. 60 c. per day, his food being paid for.

Such would be the power of production, and the cost price of the gold in the *diluvial deposits*, supposing that the work could be kept up for ten hours a-day. In the above calculations M. Laur has supposed only six men of the eight as being always at work. This is because of the time taken up in the transporting of provisions, and in cooking, &c. He has not taken into account the forced stoppages for keeping the canals, sluices, &c., in repair, and the accidents and waste in working. At the end of the year the amount of the profits is generally reduced from 35 francs to 12 or 13 francs, an average profit, acknowledged by many miners. These gold deposits can, therefore, be looked upon as producing 3½ grammes (about 2 dwt. 6 gr. troy) per man per diem. The full extent and thickness of this particular kind of *placers* have still to be determined. It would be hardly possible to form an estimate with any accuracy. They may be stated to be of such extent that it is scarcely possible to conceive them as ever entirely worked up by the pick and shovel. The excavations already made are merely insignificant breaches in the total mass of alluvium, although so much wealth has been extracted.

It would appear, at first, that the average profit of 12 to 13 francs per day would be amply sufficient to content the gold miners of California. This is, however, not the case. The digger knows that, although he is pretty certain to gain 12 to 13 francs a day, he must give up all hopes of making a *grand coup*, that may enrich him in a short time. He must abandon his dreams of suddenly acquiring great wealth. These deposits at the bottoms of the valleys are also subject to other drawbacks. The excavations made by the first miners got gradually filled with water, and become the *foci* of unwholesome exhalations, engendering dangerous fevers. The miners have therefore abandoned these deposits, and are now working another kind, called *mountain placers*, and in which the genius of the workers has obtained astonishing results.

In our next notice we will give some account of these *mountain placers*, and the interesting mechanical means used for extracting the gold of those peculiar deposits.

Literature.

Algebra Made Easy. Chiefly intended for the Use of Schools. By T. Tate, F.R.A.S., author of "Principles of Geometry and Mensuration," "The Strength of Materials," "The Elements of Mechanism, &c. New Edition. London: Longman and Co.

The rapidly increasing application of the Algebraic system to the working out of mechanical calculations, and the great advantages which palpably arise from its use are, or should be, sufficient inducements for all who are engaged in mechanical pursuits to study it. It is astonishing, indeed, that in a country so far advanced as Great Britain is in arithmetical science, Algebra should have hitherto been comparatively neglected. It has had to contend against a considerable amount of prejudice, and too often the imaginary difficulties which surround it have deterred students from attempting its mastery. The fact is, however, that the only preliminary necessary to the study of Algebra is a thorough acquaintance with the four first rules of arithmetic. If thus armed, we can assure those who are ambitious of acquiring proficiency in this branch of pure mathematics, that the task is not one of great exertion. Patient attention will enable them soon to obtain an elementary knowledge of Algebra, and this once gained, will inevitably lead the pupil to greater achievements in the same department of education.

The little work which Mr. Tate some years since published, and which has very deservedly passed through several editions, "Algebra Made Easy," is eminently calculated for assisting the mathematical tyro. Its teachings are of a transitional character, and they tempt the learner forward by gradual stages, from the plains of common arithmetic to the heights of mathematical science. Once that eminence is reached, not only is the range of mental perception immensely extended, but the thinking faculties become as it were methodised and strengthened. As Mr. Tate truly observes, "an enlightened education ought to cultivate all the susceptibilities of our nature." Algebra, which is peculiarly and justly called the analytic art, exercises, in a way which no other subject can, those powers of analysis and abstraction, which would otherwise lie dormant and enfeebled. The philosopher, embracing within the comprehensive grasp of his intellect the known laws of the universe, was once a feeble-minded child; and in order that such a child may become a philosopher, its powers of analysis and induction should be developed in a manner coresponding to its capabilities. While positive moral training should not be lost sight of, it is important to bear in mind that the patient and reflective spirit which analysis engenders gives a heathful tone, and renders us more capable of enjoying whatever is sublime or beautiful.

On all grounds, intellectual, physical, and moral, is the study of mathematics deserving of commendation; and although Mr. Tate tells us modestly that "Algebra Made Easy" is "chiefly intended for the use of schools," we have no hesitation in saying that it has a further and wider mission. It will assist young mechanics and even many practical men in obtaining an insight into what will by-and-by become an essential of mechanical education. "Algebra Made Easy," commences with the very elementary matter of definitions and notations, and ends with demonstrations of the application of algebra to mensuration.

A Key to Algebra Made Easy. By Thomas Tate. Longman and Co., London.

This is a companion volume to that which has been just noticed, and it is precisely what its name implies. It is unnecessary, therefore, to say more than that we strongly recommend both to the attention of the public.

The Screw Cutters' Guide, containing Tables of Pitches and Threads for every description of Screw Cutting; also, Tables for Gas and Ordinary Taps. By James Martin, 11, Reginald-street, Deptford.

To the mechanic in attendance on a screw cutting lathe, this unpretending little work will be of much practical use. It is dedicated by permission to Messrs. John Penn and Sons, and it is exactly what it professes to be, a guide to screw cutting. The rules are couched in plain workshop language, and the tables are clear and comprehensive. Had the "getting up" of the work, artistically and typographically, been better, and had its price been one shilling instead of two shillings and sixpence, it is our opinion that the "Guide" would have obtained a sale in conformity with its really useful character.

As it is, we recommend it to the notice of the class to whom it is most particularly addressed, and also to managers and foremen of engineering establishments generally. The author has evidently taken much pains to elucidate his subject, and his deductions are clearly the results of working experiences.

INSTITUTION OF CIVIL ENGINEERS.

February 10, 1863.—John R. McClean, Esq., Vice-President, in the Chair.

The first paper read was "Description of the Drainage of the Borough of Dundee," by Mr. John Fulton.

It was stated that, previous to 1851, this town was in a most defective condition, in a sanitary point of view. In that year the borough was brought under the powers of "The General Police Act for Scotland," but owing to a defect in the drainage clauses of the act, the sewerage was not commenced until 1856. It, however, progressed steadily after that date, and was entirely completed in five years at a cost of £52,000.

In designing this drainage, one primary object kept in view was the application of the sewage to some useful purpose, although in the meantime it was allowed to flow directly into the River Tay. Accordingly, the whole drainage, so far as practicable, had been carried to one point—the outlet of a sewer previously constructed by the harbour trustees to intercept the drainage of the town, and prevent it from entering the docks, or tidal basins. This sewer had a fall of 1 in 400, was 7 feet high by 3 feet 9 inches wide, and its discharging was 8 feet below the level of mean tide. The sewage discharged by it, in dry weather, measured 2 feet in depth, and during storms 6 feet. The velocity, in the former case, was 65 feet per minute, and in the latter, 116 feet per minute. The drainage had been carried out by a combination of brick sewers and salt-glazed, fire-clay socket-pipes, of dimensions suitable for the discharge of the sewage and the flood water combined. The whole of the brick egg-shaped sewers were provided with invert blocks of glazed fire-clay. The streets drained by tubular sewers were chiefly those at right angles with the river, which were the steepest, and therefore the most suitable for tubular drains. The proportion of brick sewers to tubular drains was as 1 to 2, the total length of the former being 10 miles, and of the latter 20 miles; and their cost was nearly as 3 to 1, the average of the former being thirty-three shillings, and of the latter thirteen shillings per lineal yard. The leading, or intercepting sewers, had been made from 12 to 18 in. deeper than the lateral and branch drains, with the view of preventing the ends of the latter from silting. It had been found that, with a fall of 1 in 600, the earthy and more soluble matters were carried off by the ordinary rain-fall and sewage, by a proper system of flushing; but a deposit of sand was left behind in all sewers having no greater fall than 1 in 600. It was not apprehended that much annoyance would arise from this cause, as none of the sewers had a less fall than 1 in 700. Passages with manholes had been carried up to the street level from both the brick and the pipe drains, at the junctions of the leading and lateral sewers, and at a distance of 40 yards along each sewer. The junctions for house drains and gullies, consisting of ordinary socket-pipes with bevelled ends to suit the form of the sewer, were built in as the work proceeded. In the case of tubular mains, socket-junctions having an acute angle, were placed at intervals of from 30 to 60 yards apart, or where required for branches, or for gully drains meant for the reception of rain water only. The gases of the sewers were prevented from escaping through the gullies by valves made of stone, and hung with copper links, placed in one side of a small cesspool, the bottom of which was 10 in. below the lower sides of the valves. This form of gully had been found very suitable in Dundee, as the valves freely passed the flood waters, while the cesspools retained all the heavier particles of road detritus. The branch drains had no other trap than the syphon with a cleansing screw, which was placed in immediate contact with the sink, water-closet, or grating used for the reception of soil-water, and in such a position as to be easily accessible.

As the water supply was in the hands of a company, it was thought that the expense of flushing the sewers from this source would have been too great. Consequently the plan adopted was to intercept the sewage, and to turn it into any sewer, or series of sewers, that might be desired. This was accomplished by means of cast-iron gates, placed at the junctions of sewers, and immediately under manholes, and in this way the greater portion of the sewers had been made self-cleansing.

The flushing gates were 15 in. deep only, and they answered the purpose of overflow weirs, preventing the sewers during floods from being subjected to pressure, by allowing the surplus contents to flow into subsidiary outlets, thus equalising the flow of water. In sewers having a less fall than 1 in 600, it was found, as already explained, that there was a tendency to the accumulation of sand; and in pipe drains with even a greater fall, where the ordinary house drainage only existed, sand also accumulated. This occasioned the invention of a cleansing apparatus. When a sewer was to be cleansed, a windlass, containing about 45 yards of iron chain, was placed over each of two adjacent entrance-ways, 40 yards distance from each other. A series of iron tubes was then put together at the bottom of one manhole, and was pushed by hand to the next, where they were again unscrewed as they were drawn through. The chain being attached to the last rod was by this means carried along the sewer, and affixed to the cleansing tool in connection with the other chain and windlass. As the matter to be removed usually consists of hard sand, a tool was first attached to the hooks of the chain, in order to plough, or break it up. When this had been sufficiently done, a scraper formed of strong plate iron, and furnished with small wheels, or moveable axles, on its lateral and lower edges, was next drawn through. It usually required to be moved backward and forward several times before the required cleansing was complete. In the case of tubular sewers, the plan adopted was somewhat different. The scraper did not require any wheels, and the plough was attached to the end of the entering-rod. The cost of cleansing sewers by this mode was, on an average, for tubular drains, one penny, and for brick drains, two pence per lineal yard. No sewer had hitherto required to be cleansed oftener than once in 12 months.

No ventilation whatever has been applied to the sewers in Dundee, and none was contemplated; for although a length of 30 miles of main sewers, and nearly as many miles of branch drains, all closely trapped, had been in use for several years, not a single complaint had been made regarding foul emanations from them. The sewers were kept free of all silt, except sand, by the flow of the ordinary sewage and rain-fall, regulated by the flushing-gates, so that no putrescent substances were retained in the sewers, or drains, to fill them with deleterious gases, and to poison the inhabitants. It was believed it was only where sewers were badly constructed, as regarded their form and water-run, that putrid matters were retained in them, to bring disgrace on the very name of drainage. It was thought that no sewer under 10 ft. in height ought to have an invert of more than 9 in. radius, and that a radius of 6 in. was quite large enough for the invert of any ordinary sewer. When the sewage was confined to such a small compass as this, its scouring power was very great; and if care were taken to have the invert blocks laid to a straight line, there would be but little silting, even with a slight fall.

In conclusion, it was stated, as the result of the drainage of the town, so far as could at present be ascertained, that, as compared with former years, a decided decrease had taken place in the rate of mortality.

The second paper read was a "Description of the Sewerage and Drainage Works, at Newport, Monmouthshire," by Mr. Alfred Williams, Assoc. Inst. C.E., F.G.S.

It appeared that, prior to the construction of the works which formed the subject of this communication, several miles of sewers and drains had been built at different times, but mostly in an imperfect manner, and without regard to any general system. There were nine open outlets into the river, varying in level from 5·4 ft. to 12·9 ft. below high water of ordinary spring tides; and the tide flowed up the sewers, and sometimes flooded the cellars and basements.

In 1856, the author received instructions from the Local Board of Health to prepare a plan for the drainage of the borough, which he so arranged—first, that the outlets were reduced from nine to four, by intercepting sewers necessary for the drainage of the districts through which they passed; power being retained to use the abandoned outlets, without additional works, should circumstances require it. Secondly, that the sewage of two-thirds of the town might be brought to the lowest outlet down the river, near the extremity of the borough; and by a further expenditure, if events should justify it, the greater portion of the remaining third might be carried to the same outlet. This was a new one selected at a suitable point for the distribution of the sewage matter in a liquid form, or for its conversion into solid manure. Thirdly, that the gradients were generally favourable, considering the level of the great portion of the district, the flattest inclination of any new sewer being 1 in 488 near the lowest outlet, and nearly half the entire length of the new sewers, being steeper than 1 in 100. Fourthly, that no cost should be incurred in works, or water for flushing, the plan being so laid out as to take advantage, for cleansing purposes when required, of the land-water and the waste water from the canal, ponds, feeders, &c., in the town, and water being also obtainable, on an emergency, from the water-works at any point.

The plan comprised about seven miles of new brick sewers, varying in height from 14 in. to 4 ft. 6 in.—all above 14 in. being egg-shaped and narrow at the invert—with outlet works; also of a sufficient number of entrances with ventilating shafts, and of street gullies. The contract for the works was let to Mr. John Phillips, and their cost had amounted to £11,862, or about 14 per cent. under the engineer's estimate, which latter was less than the average of nine tenders received for the works.

With reference to the numerous outlets, it was mentioned that the case of Newport was exceptional, the size of the river and the extraordinary rise of tide rendering the amount of sewage matters discharged into it comparatively insignificant. Of the four outlets, two were old, where a large quantity of land-water was discharged. For the remaining outlets, two points were selected suitable for the utilization of the sewage, if that should be found practicable, and not near any houses; where the sewage would have a short and steep run into the stream at low water; and where only short lengths of pipes would be required. When the outlets were closed, the sewers had for a time to act as reservoirs; but no practical inconvenience was found to arise from this, means of ventilation being provided.

The author did not consider it advisable to use stoneware pipes as main sewers, having regard to the circumstances of the town, the existing works, the relative cost of brickwork and pipes, the quantity of debris washed from the roads into the sewers, the difficulty of preventing improper interference after construction, &c. Under the Newport contract, the cost of radiating brick sewers 14 in. diameter and 4½ in. thick, at a depth of 10 ft., with a junction pipe for every house, was 7s. 7d. per lineal yard. This was about the same as a pipe 12 in. diameter, well laid, with junctions. Sewers 2 ft. 6 in. by 1 ft. 10 in., of brickwork 4½ in. thick, similarly constructed, and large enough for a man to pass through, cost 11s. per lineal yard The author generally recommended brick sewers not less than 2½ ft. high for all important lines, excepting where the fall was very great; and he confined the use of pipes to house drainage, for which they were admirably adapted, to short branch sewers on steep inclinations, and to conduits for fresh water.

The bricks were all made by machinery—the clay having been previously passed through a pug mill—some by steam and others by hand power. They had a small longitudinal hollow, which reduced the thickness of the clay, and without materially weakening the brick, caused it to be more dense and more easily burnt. For the 6-inch work, the bricks were 12 in. long by 6 in. deep and 3½ in. thick; and they were found to effect a large saving in many of the sewers, where otherwise two rings of 4½ in. work would have been used. The bricks for the 6-in. and 4½-in. rings were all made to radiate, to suit the invert, side walls, and crown of the several sized sewers; and in order to distinguish readily the different radii, as well as to afford a key for the mortar, groves, varying in shape and number, were made in the sides of the bricks. The inner and outer surfaces were curved, so that when well put together a very accurate sewer was formed.

The sewers near two of the outlets, having to act as reservoirs for about three hours at spring tides, as previously mentioned, their ventilation was effected by a large number of man-holes and ventilators combined, which were placed in open parts of the centre of the roads and streets, at a cost of £1 10s. each complete.

The rate of mortality in Newport in 1850, previous to the adoption of the Public Health Act, was 30·3 per thousand, whilst for the two years ending Michaelmas, 1861, it was rather less than 20 per thousand, or below the average of England and Wales. This very large decrease was no doubt due, under Providence, to efficient drainage and water supply, to the prevention of overcrowding, and to other sanitary measures.

Legal Intelligence.

COURT OF QUEEN'S BENCH, WESTMINSTER, FEB. 9.

(Sittings in Banco, before Mr. Justice CROMPTON, Mr. Justice BLACKBURN, and Mr. Justice MELLOR.)

HYDE *v.* PALMER.—This was an action by the assignee of a patent obtained by one Barsham in 1849, for an apparatus for separating the fibres from cocoanut husks. In 1839 Logan got a patent for improvements in preparing fibrous materials (especially for a new cloth) from the cocoanut husks, his improvements consisting of the application to the fibrous materials of artificial heat, whereby they are subjected to a twist or curl, for the purpose of giving thereto a springy or elastic quality, where they are intended to be used as a stuffing for mattresses, beds, cushions, and other similar purposes; and a particular combination of parts of machinery to perform the operation of "heckling," in the process of preparing such fibrous materials for spinning. In manufacturing the new cloth under this patent, the fibres of the cocoanut, having been first picked or sorted by hand or otherwise, are separated and loosened by means of beaters such as are used in beating hemp, or an apparatus like the apparatus called "a devil" in the flax and cotton manufacture may be used to deprive them of any foreign matters and of such of the fibres as may be too stiff and stubborn for the kind of yarn intended to be produced. This process, the inventor said, must of course be used discretionally so as to separate, cleanse, and sort the fibres with reference to the quality of yarn desired, and the process of carding or "heckling" was effected by machines constructed like the carding or "heckling" machines used in the flax manufacture. In 1841 Logan took out another patent for further improvements in preparing the fibres of the cocoanut and its husk, and under his new process, as he described it, "each portion of the husk or bundle of the cocoanut fibre being in the process caused to turn over and over under pressure, the fibres are thereby by a rubbing action among themselves caused to separate, giving off a large quantity of a very fine vegetable dust, which will be found valuable as a *snuff!*" And by the process the fibres of the husk were to be separated when they were to be further treated and prepared for spinning purposes, by submitting them to the operation of a "devil," or coarse carding-engine. Eight years afterwards (in 1849) Barsham took out the patent upon which the plaintiff now sued, which was for improvements in separating the fibres from cocoanut husks. This patentee alleged that his invention consisted of the employment of crushing rollers, for partially separating and facilitating the separation of the fibres of the husks, and of apparatus having revolving surfaces, with spikes or teeth for separating the fibres. He professed to employ the rollers in crushing the parts of the husk—first in a dry, and then when in a wet or moist state, and he admitted that rollers had been used before for the like purpose, but revolving in opposite directions. And as regarded the second part of the invention, the essence of it seemed to be in holding the piece of husk to be operated upon until the fibres are well combed out, which Mr. Grove, the learned counsel for the plaintiff, ingeniously likened to the act of a lady in combing out her hair, holding it in her hand to prevent the comb getting entangled by any knot in the hair, and so tearing or breaking it, the object aimed at, and alleged to be obtained by the invention, being the combing out the fibre at greater length and with greater thinness and fineness, and, therefore, of greater flexibility, and avoiding the risk of breaking it up into short bits or fragments. Such being the nature of the alleged invention, at the trial of the action before Mr. Justice Blackburn, the novelty being disputed, it was contended that the patent was invalid by reason of a prior user of the invention by one Oakley; and evidence was given that Oakley had, as early as 1846, used a process identically the same, and had for some years sold articles made of fibre obtained by means of that process. On the part of the plaintiff, it was insisted that this user and sale had only been in small quantities, and had not amounted to a public user, which would destroy the novelty of the plaintiff's invention. With this view, one of the witnesses for the defendant was asked, in cross-examination, whether Oakley (who was dead) had not sold a small quantity to one Smith, and, this being answered in the affirmative, Smith was called for the plaintiff in reply, and asked, whether in 1850 (after the plaintiff's "patent") Oakley had not sold him 3 lb. of the fibre, and whether he had not said at the time, "It's a new thing; don't say anything about it;" the object of which was to show that as he treated it as new even after the patent, he could not have deemed that his alleged sale and user before the patent had amounted to a public user or a "publication." This evidence was objected to on the part of the defendant, but pressed and received for the plaintiff, and the learned judge left to the jury the question of novelty on the whole of the evidence. They found for the plaintiff, and a rule had been obtained for the defendant to set aside the verdict upon the ground of improper reception of evidence, and also as against the evidence.—Mr. Grove, Q.C., and Mr. Aston, argued the case for the plaintiff; Mr. Hindmarch, Q.C. (with whom was Mr. Rosher), argued for the defendant.—Mr. Justice Blackburn delivered the judgment of the Court, which was to the effect that there must be a new trial. The inquiry was not as to the object, nature, or motives, of Oakley's act in selling the fibre in 1850 after the patent, but as to his acts of sale and user in 1846 before the patent, whereas the evidence which had been pressed on the part of the plaintiff was as to his declarations in reference to his acts of sale and user after the patent. The evidence was, therefore, inadmissible, and there must be a new trial.

BROMPTON COUNTY COURT.

(Before Sir J. EARDLEY EARDLEY WILMOT.)

WORSSAM *v.* GODWIN.—The plaintiffs in this action are the engineers of the King's-road, Chelsea, and the defendant is a railway grease manufacturer, residing at Lambeth. The action was to recover the sum of £35 for a patent pump manufactured by the plaintiffs for the defendant, from his pattern and under his supervision. Mr. W. B. Davies, solicitor, who appeared for the plaintiffs, in opening the case, said that his clients received the order from the defendant on or about the 27th of February, 1862, to manufacture for him a patent pump. No price was fixed, but the charge was a fair and proper one for the work done and the material used. The defendant was from time to time at the plaintiffs' premises examining the work, superintending experiments and trials, and watching the progress of the same, and never made a complaint of any kind. The work was completed in time for the Exhibition, and, when delivered, was found too long for the space allotted to it in the building. It was then taken back to the plaintiffs' premises to undergo some alteration, which was made in sufficient time for the Exhibition. The pump was afterwards exhibited at the Agricultural Show at Battersea.—The defendant said that the pump was too large. The space allotted to him in the Exhibition was 3 ft. 2 in. by 3 ft., and the pump was 4 ft.—Mr. Charles Parsons, an engineer, who was called for the defence, said that he had examined the construction of the pump under dispute, and he should say that the cost of such a one ought to be £21 10s.—Mr. Henry Thompson, another engineer, said that he should like to have the making of such a pump as the one plaintiffs had constructed for defendant for £18.—By Mr. Davies: The first pump would cost two or three pounds more than the other. If any alterations had to be made he would charge extra for them.—The defendant, in reply to a question put to him by his Honour, said that the pump, in its altered state, did not go the Exhibition, but it was exhibited at the Agricultural Show, Battersea.—After an address from the plaintiffs' attorney, judgment was given for the plaintiffs for £30.

THE INVENTORS' INSTITUTE.

A GENERAL meeting of this Institute was held at the Polytechnic, 309, Regent-street, London, on Monday evening last. The meeting was numerously and respectably attended. In the absence of the President, Sir David Brewster, from ill-health, the chair was taken by Admiral Sir Edward Belcher, C.B., &c., who delivered an able introductory address.

After sketching the origin and progress of the Institute up to its first general meeting, the Chairman said:—The present system involves expenses in securing a patent which press hardly on the man of small means, but too frequently found to be the real practical man of talent. And if the protective patent be withdrawn, then it is but too apparent that wealth alone will carry success, and swamp all poorer competitors; but invention, as the result of the skilled workman, must perish. One of the principal efforts, therefore, of this Institution will be directed to the reduction of patent fees. Next, it is proposed to establish such a library and record of inventions at our established home, when funds admit, as may enable inventors to search leisurely by themselves, if they please, for those inventions which may seem to clash with their own. Further, to receive models, and establish such a museum of inventions as may materially assist, not only inventors from fruitless pursuit, but serve literally as the most ample publication to the world of valuable discoveries which, perhaps, may be unnoticed until their time has expired, and they become public property. In further pursuance of this project, it is proposed to hold, during the customary meetings of other scientific societies, fortnightly meetings, when papers will be read on such subjects as may appear to the Council worthy of discussion. Inventors may here find the opportunity of meeting kindred souls, of interchanging and explaining the merits of their inventions; and, I may remark, that one very important benefit may result from such discussions, namely, that in many instances it may transpire that the supposed invention is not new; that others have preceded and established such claim as will cause them to abstain from incurring further expense and severe disappointment. On the other hand, many inventions for which patents have been obtained, and which have been dormant for the want of adequate means of bringing them properly before the public, may here have new life infused into them, and derive incalculable importance from the opinions evolved during discussion by men whose approbation alone will carry the stamp of undoubted value. Here, also, independently of records, we hope to assemble and benefit by the advice of those men of ripe age, who have buffetted the waves which wash the rocks which beset the patent office—who, from their experience, can discover between invention and borrowing the inventions of others. It is not without some degree of satisfaction that I am able to refer to the present numbers which compose our society. We now can muster in our ranks between 200 and 300 able men; and taking into consideration the short period which has elapsed since the inception of its organization, we have reason to congratulate ourselves that we have attained our present status with greater rapidity than has attended similar undertakings. And further, closely scrutinizing the names and positions in society, we stand well in talent as well as respectability. But let me urge those gentlemen who have hitherto so successfully toiled, as well as new comers, not to relax their exertions until we draw to our support the majority of the talent of the day, and eventually we trust, by our recognised utility and consequence, secure that support and solid assistance from Her Majesty's Government which has been conceded to other institutions which can bear no comparison to this as to public utility and sterling value. We are now, it is true, but an infant institution, but of gigantic promise; and we trust as our library, our models, and means advance, possibly by slow, yet sure degrees, watched, too, by the most rigid regard to economy, that a building fit to contain such treasures as we shall be able to amass may prove one of the most valuable ornaments of this capital. Doubtless it will be urged that we have other institutions already in existence fully capable of carrying out the intentions of this; such might be claimed for the original intentions of the Royal Society, the Society of Arts, and the Institution of Civil Engineers. They, however, have enough to do, and more than they can manage; and it is well known that each of these Institutions demand subscriptions beyond the reach of many talented individuals. As our members increase, we hope, at no very distant period, to attract to our support the first authorities of the day, viewed as genuine inventors; and this Institute may furnish councils of arbitration which may, in very many instances, prevent wearisome and ruinous litigation. We may help to arrest the too ardent inventor from rushing on into endless expense and mortification, by convincing him that his bantling is not his own. We may furnish him with talented assessors, who may help him advantageously, perhaps, to amicable arrangement—consolidation of schemes or of partnership—instead of wasting the sinews of war in complicated discussion in our courts of law. I am not an opponent, nor do I underrate the value of the high talent of those who stand prominent as counsel in our courts of law on patent questions. Far from it. But when the question, stripped of its mischievous technicalities, which sometimes go to rob the true inventor of his rights, has reached careful scrutiny, I should much prefer seeing the matters involved submitted to a jury of half-a-doxen men of known talent in such matters, than to sacrifice, as the law now stands, interests of the utmost value to an ignorant panel, who may return a verdict adverse to every principle of truth and science, because their limited ability or experience prevents their comprehending the matter at issue. I think I have now exhausted the outlines, and our members will deal more lucidly on particulars. Vested interests, probably, will attack our outlines, but we hope, under our inner batteries, sustained by that greatest of weapons—public opinion—we may sustain the shock, and prove that public utility and the best interests of society at large demand the victory.

Several resolutions on the subject of patent law and the cost of patents, together with a resolution pledging those present to support the Inventors' Institute, were unanimously carried, the meeting having been previously addressed by Richard Roberts, Esq., C.E., Thomas Webster, Esq., F.R.S., Hume Williams, Esq., Dr. Normandy, W. C. Fuller, Esq., Dr. Collyer, C. Varley, Esq., and many others. A vote of thanks to the gallant Chairman was also accorded, and the next meeting of the Institute was announced for Monday, the 2nd of March.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

The annual meeting of members of the above-named society took place on Saturday night last, at their Rooms in the City. In the absence of the president, Mr. Mure, of Woolwich Arsenal, was voted into the chair, and the election of officers for the ensuing year was soon after proceeded with.

The Secretary read a letter from Mr. Newton, of the Mint, which, in conveying that gentleman's resignation, thanked his fellow members for the generous support they had accorded him during the four consecutive years he had had the honour of being president. The meeting, however, were unanimously of opinion that Mr. Newton would not be spared from the post he occupied, and he was unanimously re-elected to the presidentship—subject, of course, to his renewed acceptance of it.

Mr. Mure, of Woolwich Arsenal, was re-elected vice-president, and Mr. John Jones, of the Regent's Canal Iron Works, secretary.

The auditors' report, which was next read, exhibited a very satisfactory and healthy appearance. Two new members having been elected, the business of the meeting terminated.

It was announced that the anniversary dinner of the association would take place on the 14th proximo.

SCOTTISH SHIPBUILDERS' ASSOCIATION.

December 1, 1862.

James Rodger, Esq., Vice-President, in the Chair.

(Continued from page 104.)

Remarks on the Build and Equipment of Passenger Steam Vessels. By Mr. George Barber, Shipwright Surveyor to the Board of Trade.

In sections 25 to 33 of the "Merchant Shipping Act Amendment Act, 1862," and Table (C) in the Schedule to that Act, will be found the new regulations respecting lights and fog-signals, which will come into force on the first day of June next.*

If any of you will take a walk up one side of your harbour, and down the other, and look at the position in which the side-lamps of the sailing vessels are placed, I will venture to say that you will find that not more than half a dozen vessels have them placed where they should be. You will find many nearer the stern than the bow, some placed far inboard on the forecastle, and even on the poop, and others behind fixed and permanent obstructions. You will also see that, instead of the screens being of the required length of three feet, the lengths vary from fifteen to thirty inches. One would think that there had been a fixed determination to put the lamps anywhere but in the right place, though, doubtless, it is merely the result of inattention or of a want of due consideration of the importance of the lamps being placed in the most prominent and conspicuous position possible. In the royal navy it is the practice to fix the lamps, in all classes of vessels, as nearly as possible abreast the foremost shroud of the foremast, so that all three lamps may be in one transverse vertical plane; but it is stated, though I am afraid the statement cannot be borne out by facts, that if this arrangement were to be carried out in the merchant service the glasses would be broken by the clew of the fore-sail, or the lamps would inevitably be washed away. The steam-vessels which are fitted out at this port are, as a rule, supplied with lamps of most excellent construction. Small lighthouses some of them are; but I am afraid, from what I have seen, that in many cases the oil which is used is not worthy of the lamp. Cheap oil, or any kind of oil, ought not, for ships' signal-lamps above all others, to be preferred to the best oil; and I am sure it will not be necessary for me to bring forward any argument in support of this statement.

The following extract from the instructions issued by the Board of Trade to their surveyors has reference to signals of distress, and you may, perhaps, consider the remarks about the mortar worthy of consideration:—"The signals of distress are to be carefully examined by the shipwright surveyor, to see that they are kept dry and in good order, and are protected from fire and accident, and that the cannon, which is to be sufficiently large, is in good condition, and ready for use. The signals required are—

12 Blue Lights, or
12 Port-fires and 1 Cannon, with ammunition for
12 Charges.

"Surveyors should call the attention of masters and owners to the advantages of having a 24-pounder mortar in lieu of a gun, to be used as a signal of distress, as it would serve to carry a line to the shore in the event of the vessel being in distress on the coast, and might be the means of saving the crew, when no boat could put off; the life-lines provided for the mortar and rocket apparatus at the various coast guard stations could, in such cases, be made available. Where guns are already provided, there will probably be difficulty in getting the change made; but in the event of old guns being replaced, or in the case of vessels fitting for the first time, it is very desirable that the advantages of the mortar should be pointed out."

You will scarcely believe that in such a simple, though important article of equipment as a life-buoy, economy is often studied before efficiency; but such is the fact. Reeds and rushes sometimes take the place of cork; and although life-buoys made of these present, when new, a very fair exterior, and may perhaps answer their purpose for a few weeks, I have known instances in which, when I have had them thrown oberboard, they have immediately disappeared. Gutta-percha life-buoys have been tried, but the objection to them is their liability to crack. I believe that the well-made cork life-buoys—not those made of cork parings, but those which are composed of segments of solid cork, and covered with strong, well-painted canvas—are the best. And I think it would be a good thing if large passenger steam-ships were supplied with one of that description of life-buoy which you may see suspended from the sterns of her Majesty's ships. It is composed of two hollow copper globes, secured to a framing of wood, and it can be instantly detached from the stern by a trigger. The moment it is set at liberty a fuse, which is attached to it, and which will burn for a considerable time on the water, is ignited, and this serves to indicate the position of the buoy to a drowning person. While I am on this subject, I may state that the life-belts, of which this is a sketch, and which are made on the plan proposed by Captain Ward, R.N., the Inspector of Lifeboats to the Royal National Life-boat Institution, have been found to be a valuable means of saving life;* and I cannot forbear mentioning that the excellent and liberal arrangement, recently adopted by the Cunard Company, of having a good cork life-buoy attached to the end of every sleeping berth in the ship, is well worthy of imitation.

During those days of dense fog which we had last week, I put to myself the question, which I now put to you, Where are the "leads" carried in a steam vessel? You will say, In the wheel-house, or in the mate's room, or, if not there, in the boatswain's store-room., Now you know the importance which is attached to the use of the lead; and why should not the hand-lead, at any rate, be kept always on deck or upon the bridge? It would not then have to be sent for, or sought for, but would be ready to put over the side at a moment's notice.

On looking over the discussion which took place on the paper read to you by Mr. Walker, on the 6th May, 1861, I find it stated that if the Commissioners of Northern Lights were to be applied to, it was most probable that, in conjunction with the Clyde Trustees, they would lay down buoys and establish other appliances for facilitating the swinging of ships for the adjustment of their compasses. I had occasion to be at the Gareloch a few days since, and I find that nothing has yet been done in this matter. I hope it will not be allowed to drop altogether; for I am sure that you must all be aware of the necessity of a careful adjustment, and of the importance of affording every possible facility to the adjuster.

There is one other subject on which, before I conclude, I should like to say a few words. I have often spoken of it privately, and as I have failed to attain my object, I will make no apology for now speaking of it publicly. A great number of steamers are about to be built for your river and coasting service, and I am anxious that, when you are getting out their deck and cabin arrangements, you should make some improvement upon the arrangement of water-closet accommodation which at present exists. The Legislature of this country and of America have, as far as emigrant ships are concerned, laid down fixed rules on this subject; but I want you to take the matter in hand yourselves. I do not complain of the plumbers' department, for there is ample evidence to prove that the Clyde plumbers have given the subject the greatest possible attention; but I complain of the inadequacy and unsuitability of the present arrangements. Come with me on board any of your first-class coasting steamers, and let us see what the cabin arrangements are. A spacious and beautifully decorated saloon; elegant skylights; comfortably arranged sofas; a large and well appointed pantry; state rooms, with sleeping accommodation for sixty or eighty persons; four or six roomy wash basins; but for this large number of passengers, how many water-closets are there? One. Only one. And where is it placed? Anywhere. In any corner, no matter how small or dark, which could not be appropriated to any other purpose. Look into the ladies' cabin. There are eighteen or twenty sleeping berths; and ever in one corner—perhaps placed angle-ways—and opening directly upon the heads of two tiers of sleeping berths, there is a door—not larger than one of the doors of your bookcase,—and this excludes from view a miserable, uncomfortable, little bit of a sentry-box, not more than thirty inches square, and barely high enough to sit upright in. We will not go and look at the accomodation provided for the fore-cabin and steerage, for if we do we shall turn away in disgust. Your river steamers are as bad, if not worse, in this respect; and I firmly believe that many a passenger has suffered and many a one will suffer, an untold amount of agony, rather than enter one of these wretched, dark, ill-contrived, badly-ventilated places, which are a disgrace to the other arrangements of the vessel. No doubt a great deal may be said about the carelessness of passengers themselves; but in these new steamers which are about to be built, and of which such great expectations as to speed and beauty are entertained, see whether you cannot make some improvement. Give more room, more liht, more air. In the ladies' cabin take it out of the corner, and give it a square, roomy place by itself. And in the river steamers see whether you cannot arrange a fit place for any one to go into. If you will do this, you will have the thanks of that large multitude of passengers which crowd your steamers during the whole of the summer season. It is also very desirable that an improvement should be made upon the present arrangement of companions and ladder ways in your river steamers. Every one who has travelled in your river steamers must have experienced the inconvenience of the present arrangement, and many, I doubt not, have with myself, thought how utterly impossible it would be, in the event of an accident occurring, for the passengers in the cabin to get upon deck in a reasonable time. No one would now think of putting a narrow, inconvenient staircase, with the old fashioned, dangerous, wedge-shaped steps into a house, and why should you continue to put them into your steamers? Why not put the companion in the middle line, and give a wide, easy stair? You would get quite as much passenger space on deck; there would be less danger to children and females when descending; and in the event of an accident happening to the vessel, the passengers would be able to get upon deck without that confusion and loss of time which would be sure to arise from the obstruction caused by the present arrangement.

---

* The sections referred to were read to the meeting, and copies of the Act can be had from any publisher for eighteenpence.

* During the storm of the 9th February, 1861, the Whitby life-boat capsized, and twelve out of thirteen of her crew perished, the man saved being the only one who had on a life-belt of this description.

I have directed your attention to a great many subjects, and I now invite you to a discussion upon them. I have had something to say about iron decks and ships built of a combination of wood and iron; about the plaining of butts and the necessity of pipes which pass through the ship's side being exposed to view; about preservatives for ships' bottoms and the importance of keeping the inside of iron vessels well coated; about leaky forcastles and square butts to deck planks: about rudders and rudder-pendants; chain cables and hawse-pipes, and a chain testing machine; about pumps and pump roses, boats, boats' davits, arrangements for giving buoyancy, appliances for lowering and disengaging, and the desirability of boats being exercised; about signal-lamps and signals of distress, life-buoys, leads, and compasses. You may, perhaps, have thought that some of these were matters scarcely worth speaking about; but, trivial as they may appear, they have an important bearing upon safety; and "safety" you know is the only text which I have to study. I hope you will not think that I have spoken too plainly; and if what I have said will induce you to take the matters to which I have referred into your consideration, and to give to safety some share of that attention which I have reason to fear is too often given to saving, I shall not regret having occupied this evening so much more of your time than I intended.

The CHAIRMAN.—I am sure we have all listened with great interest to the remarks and suggestions made by Mr. Barber, and I hope that any member who may wish to offer any observation upon, or to discuss any of the numerous topics which have been referred to, will now do so.

Mr. DUNCAN.—I have heard with surprise the statement made by Mr. Barber respecting side-lamps. I had thought that, as a rule, vessels built and fitted on the Clyde were most particularly attended to in that respect.

Mr. BARBER.—I did not intend my remarks about the positon of signal-lamps to apply to any particular vessel or vessels, but to the sailing vessels generally frequenting the port. I shall be glad to hear from any member who may be disposed to go and see for himself, that my statement is incorrect. I hope that, by the next meeting, there will not be a sailing vessel in the port to which my remark about the position of lamps will apply.

Mr. BOOLDS, of Greenock.—I would like to ask Mr. Barber whether he is of opinion that all vessels should have iron decks, or to what class or description of vessel he considers iron decks most useful as a means of strength?

Mr. BARBER.—I believe that iron decks are very valuable in vessels whose length bears a great relative proportion to their breadth and depth, So much longitudinal strength is afforded by them. In small vessels the necessity for iron decks is not so great.

Mr. DUNCAN.—Who can understand now-a-days what is meant by a long ship? At one time five times the beam was considered an extraordinary length, but now we think nothing of making vessels of a length of nine times the breadth.

Mr. BARBER.—I will not dispute that there is a difficulty in comprehending what is meant by a "long ship." I believe, however, that if, after a voyage, a vessel shows unmistakeable signs of weakness, it is a proof, not, perhaps, that the length is too great, but that the strength is insufficient for the length. The dimensions of the first iron vessels with iron upper decks which came under my observation were 300 ft. × 34 ft. × 24 ft.; the next were 310 × 34 × 24; the next were 335 × 34 × 24, and I believe that some vessels are now being built of the dimensions of 390 × 34 × 24.

Mr. BROWN, of Renfrew.—I did not exactly understand Mr. Barber's observation about shaft-tunnels. It is not necessary that tunnels should now be made water-tight.

Mr. BARBER.—You will not find any mention made of screw-tunnels in the Act of Parliament. The Act required the bulkheads to be entire and water-tight; but on its being represented that great inconvenience was caused by the engineers having to go out of the engine-room into the after-hold or after-cabin to get at the bearings, the Board of Trade consented to an entrance being made through the bulkhead, provided there was a water-tight tunnel and a water-tight sliding over the entrance. Under this arrangement no water could get from the engine compartment into the after-hold, nor from the after-hold or stern-tube into the engine compartment. Builders and owners are at liberty now to make their own arrangements of bulkheads and tunnel, and I trust that they will not depart from those arrangements, which, as regards safety, have hitherto been found to be so valuable.

MR. DARLING.—Are we then to understand that an owner can send a passenger vessel to sea without bulkheads?

MR. BARBER.—He may do so, but it is not probable that he will take upon himself the reponsibility of doing so if it be the general opinion that bulkheads conduce to safety. Owners have hitherto thought it sufficient to have a clause put in their specifications to the effect that the "Bulkheads are to be to the satisfaction of the Board of Trade surveyor." They have felt assured that the vessel would not get a certificate if the bulkheads were not as they should be. In future, however, they will have to trust entirely to their own inspectors, or to the builders, and not, as the have hitherto done—to the Board of Trade surveyor. The surveyor may not have the legal power to insist upon bulkheads, but he will have to satisfy himself that the vessel is sufficiently strong for the service for which she is intended, without regard, however, to the probability of her going upon the rocks. Masters must take care to keep their vessels off the rocks.

The CHAIRMAN.—But is it not a fact that in all cases in which an iron ship has gone ashore she has parted at the bulkheads first?

Mr. BARBER.—No; it is not a fact. It is the popular notion, but it is not a fact. The instances in which vessels have parted at the bulkheads are very few in comparison to those in which vessels have been saved. The former cases are noised abroad; the latter are seldom if ever published, and are known only, perhaps, to the owners, to the crews, and to the surveyors. The tendency to tear at the bulkheads might be, and has been, obviated by the simple method of doubling the ship's side in the wake of them.

The CHAIRMAN.—That would only make the vessel more rigid at those particular places.

Mr. BARBER.—Well, I will not go so far as to say that bulkheads give strength to a ship. I will not go into that question. I contend, however, that a vessel with properly fitted water-tight bulkheads has, within herself, a means of safety that a vessel without bulkheads has not; and I will also maintain that bulkheads can be fitted in such a manner as not to weaken the ship. I could refer to many, very many, instances in which vessels of all classes, and when engaged on all services, have been preserved from sinking, after having been in collision with icebergs, or with other vessels, by their bulkheads.

The CHAIRMAN.—I believe that bulkheads are most valuable in cases of collision, and I do not believe that the repeal of the 300th section of the Merchant Shipping Act will in any way affect the practice of fitting bulkheads which has been hitherto carried out by the Clyde shipbuilders.

Mr. BARBER.—I hope not. I hope that bulkheads will continue to be water-tight bulkheads, not thin "brown paper" divisions, put in merely to keep the engines and boilers apart from the cargo and cabins.

Mr. SKINNER.—It cannot be expected that a man is going to build a ship to run upon the rocks. He wants his ship to carry his cargo, and to do her legitimate work. Running upon rocks is not her legitimate work, and if the surveyors will see that vessels are made strong enough, and are sufficiently equipped for their legitimate work, it is all that the public can reasonably expect from them.

Mr. ARMOUR.—I beg, sir, to move that Mr. Barber be requested to allow the remarks which he has made to be printed, so as to form part of the proceedings of this association.

Mr. HAMILTON seconded the motion, and it was carried unanimously.

Mr. BARBER, in reply, said that the remarks which he had made had been very hurriedly put together, and with the intention that they should not form part of the regular proceedings of the association, but as the meeting appeared to be of opinion that they were calculated to do good, he would not object to them being printed.

A selection of specimens of iron and steel (numbering 490), upon which the experiment published in Mr. Kirkaldy's book were conducted, were then examined by the meeting, and a short discussion took place, in which the truthfulness of the inferences deduced by Mr. Kirkaldy was made manifest. Many of the members bore testimony to the patience and impartiality with which the experiments had been conducted, and to the care and precision with which the results had been arranged and recorded.

LIST OF THE SPECIMENS CONTAINED IN FIVE CASES, namely:—

IN CASE I.

9	Iron bars, showing elongation and laternal contraction.		
1	Iron plate,	do.	do.
1	Steel plate,	do.	do.

IN CASE II.

42	Steel bars, showing fractures and contraction of area.		
105	Iron bars,	do.	do.

IN CASE III.

36	Steel plates,	do.	do.
60	Iron plates,	do.	do.
24	Angle iron, &c.,	do.	do.

IN CASE IV.

36	Iron bars, showing fractures and effects of difference in the shape.		
40	Iron bars, showing fractures and effects of difference in the treatment.		
12	Steel bars,	do.	do.
10	Iron plates,	do.	do.
15	Iron bars, showing fractures and effects of strains suddenly and gradually applied.		

IN CASE V.

46	Iron bars, showing fractures of screwed bolts.		
12	Iron bars, showing fractures of welded joints.		
2	Steel bars,	do.	do.
26	Iron bars, showing textures as developed by acid.		
8	Iron plates,	do.	do.
1	Iron plate, showing surface "cold-rolled."		
4	Iron bars,	do.	do.

Mr. BOOLDS proposed, and the meeting unanimously accorded, to Mr. Kirkaldy a vote of thanks for the trouble he had taken in arranging his collection of specimens for their examination.

SOCIETY OF ARTS.

FEB. 11, 1863.—W. R. GROVE, Esq., Q.C., F.R.S., in the chair.

The paper read was "On Submarine Telegraphy," by Mr. Thomas Webster, M.A., F.R.S.

The author observed that this subject naturally resolves itself into the questions of the route, the cable, and the means of submersion. Public attention had been directed to three routes across the Atlantic—the central, the northern, and the southern, each presenting peculiar advantages and difficulties; the first being the one to which attention was directed in 1856, and in which the cable was actually laid. Since that great experiment much precise information had been attained as to the working, and the speed attainable in circuits of great length. It appears to have been ascertained that the rate of working a number of signals transmissable through two lines, identical in every respect except as to length, is inversely as the square of the ratio of the lengths. This, which depends on a physical law of nature, is wholly independent of artificial and external conditions, as the insulation, which, however perfect, cannot effect the comparative results, and the shorter must always, in the author's opinion, have a commercial advantage over the longer cable, which must necessarily influence the selection of routes. These and other considerations have called attention to two other routes for the Atlantic telegraph cable; one, the northern, from the west coast of Scotland, by the Faroe Islands, Iceland, and Greenland. to the east coast of Labrador, and the southern from the south coast of England, by the Canary and Cape Verd Islands to St. Paul, a small island in the South Atlantic Ocean, and thence by the island of San Fernando to Brazil, and so along the coast of British Guiana and the West India Islands to America. Both these routes present a convenient mode of dividing the distance into a series of short and manageable circuits. Mr. Webster stated the reason for his opinion that the laying of the cable on these routes, in comparatively short lengths, would present no serious difficulties, though the number of shore ends was doubtless a disadvantage. He thought that the submerged cable in the Northern Atlantic, would, in the opinion of the most experienced sailors, run little risk of damage. An accurate knowledge of the bottom of the ocean was of the greatest importance to such a question, but even this knowledge might be bought too dear. Soundings in deep water, say from 1,500 to 3,000 fathoms, over a breadth of four or five miles, would present serious difficulties, and would occasion a delay unfavourable to the success of the enterprise. The question of the cable was, however, secondary to the selection of the route, as the weight, dimensions, and construction of the cable would in all probability be different for the Central or Northern Atlantic; still these questions were matters of great importance; the author proceeding to touch upon the principal points on which difference of opinion existed, such as the alleged objections to the spiral construction of the external wire covering, the substance to be used for insulation, the influences of magnetism and the *aurora borealis* on cables already laid, and other matters. He then passed to the question of the best mode of laying the cable, touching incidentally upon the different sorts of strains to which cables of high and low specific gravities were respectively exposed during this operation. In conclusion, he expressed an opinion that a regular inquiry by competent persons into all these subjects would lead to most valuable result.

PROCEEDINGS OF THE INSTITUTION OF MECHANICAL ENGINEERS.

ON THE MANUFACTURE OF HEMP AND WIRE ROPE.

BY MR. CHARLES P. B. SHELLEY.

(Continued from page 94.)

As the spinner proceeds down the walk he tosses the yarn with his left hand on to one of the hooks in the rafters, in order to support it; and in coming back he jerks it off again. The distance of one-third, two-thirds, and 160 fathoms, are chalked on the side of the shed, and as the spinners of each set come to the distance, they shake their yarns, and thus signal to the man at the machine for the yarns to be unhooked and reeled up. Each spinner is paid in London 9d. for spinning six threads or yarns, each 160 fathoms long; this is called "one quarter's work," and each spinner spins four threads an hour.

The yarns are distinguished and designated by their size or number of thread, every size being numbered; the ordinary numbers, beginning with the coarsest yarn and going to the finest, are 18, 20, 25, 30, and 40. Number 20 is the most usual size, and is employed for "London staple cordage;" number 25 is used for Government yarns, number 30 for bolt rope yarns or the finest description of cordage, and number 40 for whale lines. In spinning number 20 size, the "shorts," are always worked in with the "long hemp;" but for finer sizes, 25, 30, and 40, "long hemp" alone is used, in order that the yarn may be even and smooth. The size of the yarn is determined by the number required in each strand to make a rope of 3 in. girth with three strands; thus the size of number 20 yarn is such that 20 yarns in each strand will make a rope of 3 in. girth with three strands. Number 20 is said to be the usual "grist;" number 25, 30, and 40, are said to be finer "grists."

If the cordage is to be tarred, it is done at this stage of the manufacture, before the yarns are formed into strands; but the process of tarring the yarns will be described subsequently.

When the reel behind the spinning machine has been filled with the four lengths of yarns spun, it is taken to the winding machine, which separates the four yarns on to four separate bobbins, and also reverses the lay of the yarn end for end so that the fibres may lie in the proper direction for passing through the next process. The full reel containing the four yarns from the spinning machine is mounted on a temporary frame behind the winding machine, and the ends of the four yarns are led to the bobbins over a sliding bar, which has a vertical reciprocating motion given to it by the cams and levers, for the purpose of filling the bobbins regularly and equally from end to end. Other forms of winding machines are used, but the principle of construction is the same in all. When the four bobbins are filled, they are replaced by empty ones, until the whole of the reel from the spinning machine is wound off upon bobbins. The four full bobbins are then taken away and placed vertically in a large wooden frame called the bobbin frame, which holds from 150 to 200 bobbins. Each bobbin contains about 14 lbs. of yarn.

The next process is that of twisting a number of yarns together into a strand, which is termed "forming," and is done in the "forming" machine, and in the shed covering the rope walk. Having ascertained the number or size of the thread that is of sufficient thickness to form the required strand, the number of yarns corresponding to that size of thread are selected; and the ends of the yarns of this size are drawn from the bobbins and brought in a converging direction to a square iron plate, called the "register" plate, perforated with a number of round holes. Each yarn is made to pass through a separate hole in the register plate, and the yarns all converge thence into one common point through the forming board, in which is a taper steel tube with a trumpet-mouthed taper hole through it. The hole in the tube varies in diameter for each size of strand, and is selected by a gauge: the diameter of the tube for one of the strands for a rope of three inches girth is eight-sixteenths of an inch at the small end, and nine-sixteenths of an inch at the large end, and for the strands of a rope of two inches girth, it is five-sixteenths of an inch at the small end, and seven-sixteenths of an inch at the large. The convergent yarns are entered into the tube at the large trumpet-mouthed end, and are forced through, fitting tightly into the tube; they are thus squeezed together previously to being attached to the forming machine.

In the next process the strands are "laid" into a rope by two "laying" machines, one at the upper end of the walk and the other at the lower end. In this process, instead of being twisted together as the yarns are in the previous "forming" process, the strands are placed or "laid" in their spiral position in the rope without being twisted. The laying machine at the upper end of the walk is fixed, and the three strands to form the rope are attached to the hooks, which are made to revolve in a similar manner to those in the previous forming machine, by the fly rope passing round the wheel. The lower end laying machine is left free to travel part way up the walk as the length of the strands becomes shortened by their being laid into a spiral in the rope. The wheel drives two "forelocks," to one or other of which the strands are made fast, according as the twist of the rope is to be right-handed or left-handed. The three strands for the rope are stretched tight along the length of the walk from the hooks of the laying machine at the upper end to the forelock of the lower laying machine, and are supported off the ground and kept separated by means of posts, called "samson posts," placed at every five fathoms' length, with pegs to carry the strands. A taper piece of wood with three grooves, called the "laying top," is then inserted between the strands close to the lower machine, with its smaller end towards the forelock, one of the strands lying in each of the grooves. A transverse hole is made through the laying top, through which is passed the "top stick" or handle that the top is held by. The laying tops are made of various sizes according to the size of rope required: for a rope of 3 inches girth, the top is 12 inches long, 10 inches diameter at the larger end, and 8 in. at the smaller. When the rope is more than 3½ in. in girth, a "top cart" is used for supporting the top.

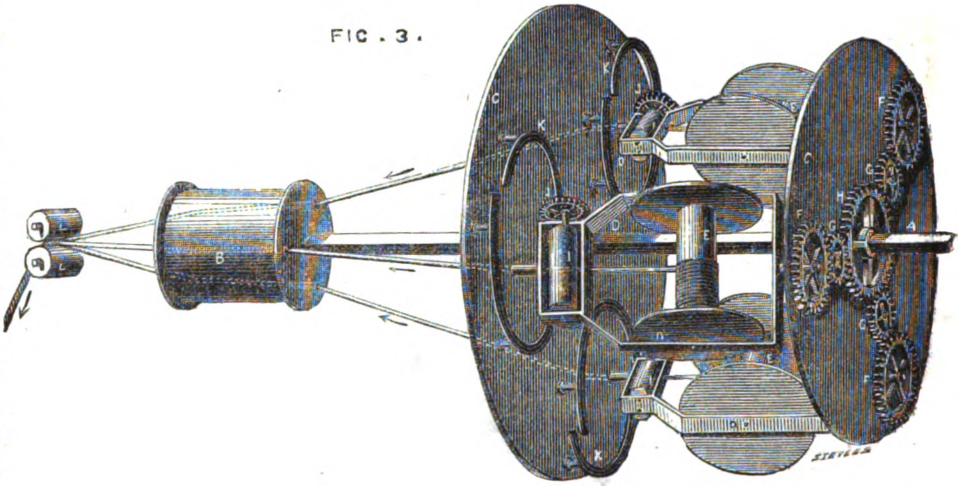
The laying machines being put in motion, the revolution of the forelock gives the twist or "hard" of the rope, while the laying top is firmly held by the handle from turning. The hooks at the other ends of the strands are made to revolve in the opposite direction to the forelock which is twisting the rope, so that the twist put into each of the individual strands, at the point where they are united into the rope immediately behind the laying top, is taken out again by the hooks at the upper end. The laying top is gradually pressed forwards by the closing of the strands upon one another behind it; its motion requires to be very regular, and it is prevented from moving forwards too fast by a "tail" or piece of rope attached to the top handle, which is coiled round the rope already twisted, and thus acts as a drag to the top. The two laying machines must be driven at exactly the proper speed relatively to each others so that the twist put into the separate strands at the laying top may be exactly neutralized by the revolution of the hooks: otherwise if the hooks revolve too slow, they will partially untwist the individual strands, since the twist of the yarns in each strand is in the contrary direction to that of the strands in the rope; or if too fast, the strands will become twisted tighter. In order that the man holding the laying top may find out how the machines are working, whether too fast or too slow relatively to each other, he makes a mark on one of the strands close to one of the supporting posts: if the strands are being twisted too fast by the hooks of the upper laying machine, the mark on the strand advances towards the upper end of the walk, from the yarns themselves becoming twisted tighter together in each strand, whereby the length of the strand is shortened; but if too slow, the mark recedes towards the lower end, from the partial untwisting and consequent lengthening of the individual strands. In laying the strands care is required with regard to the angle that the strands take. Should the tension on the strands become unequal, the required additional twist is given to those which have got slack by throwing out of gear those hooks of the upper laying machine to which the tighter strands are attached, and allowing the others to continue revolving until all the strands have again become equally strained. As the formation of the robe proceeds, the lower laying machine is gradually drawn up the walk by the shortening of the strands as they are laid together into the rope; and weights called "press weights" are placed on the frame of the machine to retard its motion and hold the rope tight enough during the laying Formed strands of 180 fathoms length will make 120 fathoms o hawser-laid rope; the length of the strands will be determined by the length of rope required.

After the rope is taken off the laying machines, it is coiled on to a drum driven by steam power, being guided from end to end of the drum by the workman, whose hands are protected by a piece of old cordage twisted on the rope that is being coiled; this gives a polish and finish to the surface of the rope.

The previous description has referred only to ropes manufactured by hand. In the application of machinery to this manufacture, which is next to be considered, Mr. Cartwright appears to have invented the first rope-making machine, which is the basis of others since constructed, his "Cordelier" having been brought out in 1792. Fig. 3 shows a sketch of the cordelier, which revolves on the horizontal shaft A, the laying-top B serving as the bearing at one end of the shaft, having holes through it for the strands to pass through. In the discs C C fixed on the shaft A are centred the three horizontal spool frames D, carrying the spools E which contain the three strands to be laid together. As the cordelier revolves, the axes of the spools are preserved constantly parallel to themselves by the spool frames D being made to rotate on their bearings once for every revolution of the machine, by means of the pinions F on the spool frame bearings, and the counter wheels G gearing into the central dead wheel H, which is of the same diameter as the pinions F, and is held stationary while the shaft A revolves within it. The bearings at the other end of the spool frames D are hollow, for the strands to pass through to the laying-top B. The strand is drawn off the spool by the pair of delivering rollers I, which receive motion by a worm wheel J on the axis of one of them gearing into the worm K, within which the spool frame revolves. The drawing rollers L L draw the finished rope forwards as fast as it is made, and hold it from turning.

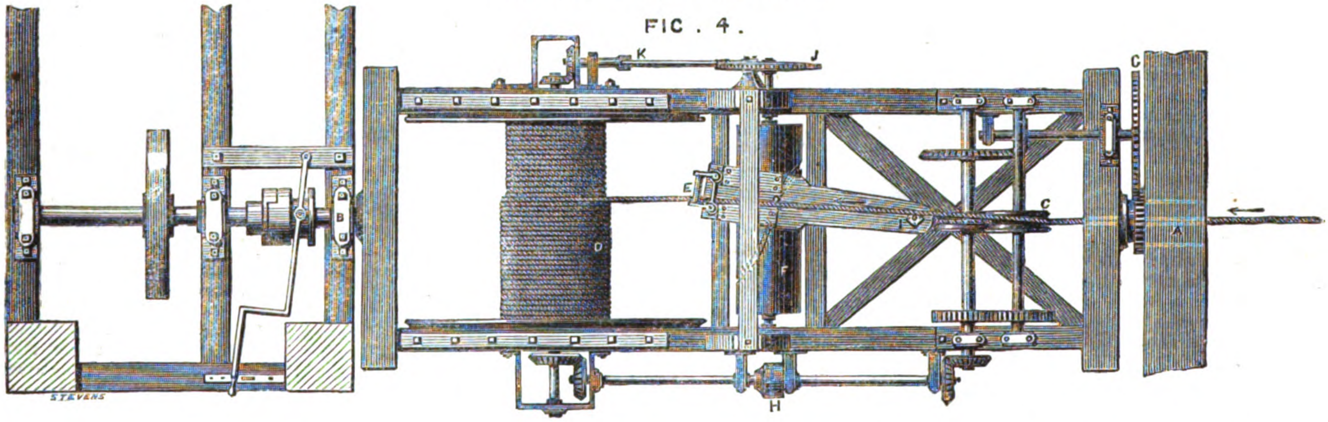
CARTWRIGHT'S CORDELIER.

FIG. 3.



THE REGISTERING MACHINE.

FIG. 4.



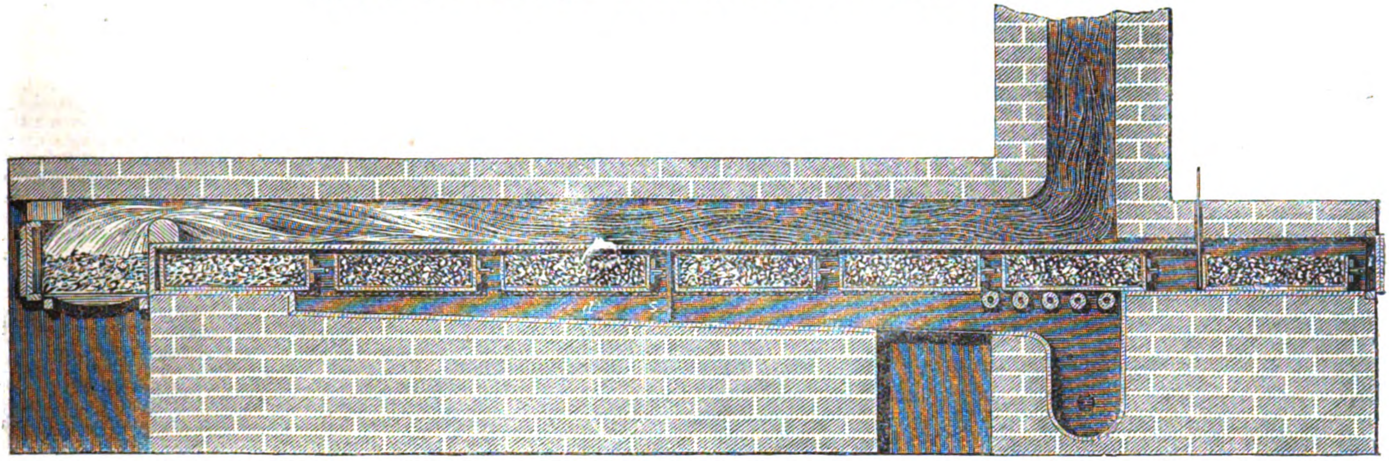
This machinery was a few years afterwards improved upon by Capt. Huddart, who constructed machines that were used for a number of years at the Deptford dockyard for spinning the yarns and for the manufacture of ropes and cables; and the author is mainly indebted for the following particulars of the construction of this machinery to a description and drawings given in the professional papers of the Royal Engineers by Mr. John Miers.

If the ropes are to be tarred, the tar is applied to the yarns on leaving the spinning machine. For this purpose they are first wound off from the drum behind the spinning machine upon a winder called a "whimwam," made of a light open frame of iron and wood revolving on a horizontal shaft. The loose ends of the four yarns on the drum are attached to a hook at the right end of the winder, which is then turned by a winch handle to wind the yarns on, the yarns being being guided on from end to end by a traversing plate with four holes in it which receives the required traverse motion from the shaft of the winder. On reaching the left end of the winder the yarns are doubled round the hook at that end, and the winch is then turned in the opposite direction, winding the yarns on till they reach the right end, where they are similarly doubled round the hook at that end, and the winding is then again reversed. When a sufficient quantity of yarn has been put on the winder, the hook at one end is taken out and the yarn is uncoiled from the winder, thus forming a long skein called a "haul," which is then coiled upon a small circular revolving platform called a "turntable," about 4 ft. diameter, mounted on wheels. The haul of yarns is then taken to the tarring shed, and uncoiled from the turntable into a cauldron of tar heated by fire or steam; one end of the haul is lifted from the tar, and means of a capstan is drawn through a sliding nipper or squeezer for the purpose of squeezing out the superfluous tar from the yarns. After the haul has lain for some time, the longer the better, the four yarns are separated and wound on to four bobbins by the winding machine previously described; and are then passed to the bobbin frame ready for being twisted into strands. Capt. Huddart did not make the yarns into a haul previous to tarring, but passed them from bobbins direct from the spinning machine through the tar and thence through nippers to the register plate of his registering machine about to be described. The length of a haul is 55 fathoms; it contains about 144 threads, and takes about 20 minutes to pass through the squeezer from the tar cauldron, that is about 16 ft. in a minute. The tar used should be the best Archangel tar, of a good bright colour, and heated to a temperature of 212 deg. Fahr. The usual proportion of tar remaining in the yarns is from one-quarter to one-fifth of the weight of the untarred yarns. The yarns when tarred ought to be of a bright brown colour.

The "Registering" Machine, shown in plan in Fig. 4, is for the purpose of twisting the yarns into a strand and winding the strand upon a drum as fast as it is formed. The whole machine revolves with rapidity on the horizontal bearings A B, being connected with the driving power by a sliding friction crutch at B. The strand enters through the hollow bearing A, which grips it tight and thus twists the yarns into the strand by its revolution. The strand is drawn in by the pair of drawing pulleys C, taking half a turn round each, and is delivered upon the winding drum D by the guiding frame E, which is made to move from end to end of the drum by means of a stud on the frame working in a spiral groove cut in the barrel F. The drawing pulleys C, winding drum D, and grooved barrel F, are all driven from the spur wheel G gearing into a stationary pinion fixed to the plummer block in which the bearing A revolves. As each successive coil of strand wound on the drum D increases its diameter, whereby an increased tension would be thrown on the strand, a friction clutch is inserted at H in the intermediate shaft which communicates the driving motion from the drawing pulleys C to the winding drum D, in order to prevent the drum from overwinding the pulleys, the friction being adjusted to the exact limit of tension desired in the strand. The guiding frame E which delivers the strand from end to end of the winding drum vibrates on a centre at I, and its rate of travel is varied for different sizes of strand by changing the worm wheel J on the spindle of the grooved barrel F; the universal joint K allows of the driving worm being set at different inclinations for gearing into a larger or smaller worm wheel J.

The strand made by the registering machine is wound off the drum D on to a loose reel, so that when transferred to the drum of the spool

WILLIAMS'S APPARATUS FOR THE DISTILLATION OF COAL AND PEAT.



Longitudinal Section.

frame in the laying machine it may lie the same way end for end as on the drum D, in which state it is ready for being laid into a rope. The length of the strand is measured by passing it over a pulley of definite diameter, to which is attached a counter with a dial indicating the number of fathoms of strand that have passed over the pulley.

(To be continued.)

WILLIAMS'S APPARATUS FOR THE DISTILLATION OF COAL AND PEAT.

Mr. W. M. Williams, of Handsworth, has recently patented an arrangement of apparatus for the distillation of coal and peat, and such other substances used in the manufacture of volatile hydrocarbons. The accompanying engraving shows a longitudinal section of the furnace. The distillatory vessel or chamber, having a top or cover, is made of iron, and constitutes the bottom of the reverberating arch. The bottom of the distillatory vessel or chamber is inclined as represented, the lowest end being that most distant from the fire. A portion of the bottom of the distillatory vessel or chamber is made of thin sheet zinc, and is unsupported by brickwork.

The object of this arrangement is hereinafter explained. The distillatory vessel or chamber expands downwards, near the back of the furnace, and forms at that part a condensing chamber, which may be cooled by water. The distillatory vessel is prolonged beyond the condensing chamber, as shown. This prolonged part is terminated by a door, and may be temporarily cut off from the distillatory vessel or chamber by a valve or damper. At the furnace end of the distillatory vessel or chamber is a lateral chamber, which opens at one end into the distillatory vessel or chamber, and at the other into the air. The said lateral chamber may be closed by a door, and may be cut off from the distillatory vessel or chamber by a valve or damper. This chamber forms the discharging chamber. The trays containing the coal or other matter to be treated, may be run in on rails. Or, instead of rails, a series of rollers may be employed. The position of a few of these rollers is indicated in the engraving. The coal or other substance to be operated upon is placed in shallow trays, which may be from 6 to 12 in. deep, and square or oblong in shape.

In using this invention the fire is lighted, and maintained in the furnace to keep the iron plate at a bright red heat at that part nearest the fire. The trays being filled with the coal, peat, or other material to be operated upon, are introduced into the charging chamber one at the time.

The door *i* of the chamber having been closed, the damper or valve is raised, and by means of a rod passed through a hole in the door the tray is pushed into the distillatory vessel or chamber *d*, and on to the rails or rollers. The tray thus introduced is left for a short time at that part of the distillatory vessel or chamber most distant from the furnace, when a second charged tray is introduced in a manner similar to that by which the first was introduced, the second tray pushing the first before it. Other charged trays are introduced until the distillatory vessel or chamber is filled with them, the one first introduced having arrived at the end of the distillatory vessel or chamber nearest the furnace. The contents of the trays having been sufficiently heated after they have been respectively brought to the furnace end of the distillatory vessel or chamber, and allowed to remain there, being the interval elapsing between the introduction of one tray and the introduction of that succeeding it; the trays are withdrawn from the furnace end at the same rate as others freshly charged are introduced at the charging chamber. The withdrawal of the trays is effected at the discharging chamber, placed latterly as before described. In withdrawing a tray the door is closed, and another valve or damper raised; the tray is pulled out by a rod in a similar manner to that described for the charging. The interval of time allowed between the introduction of the trays is such that the distillation of the material in the first tray shall be nearly completed by the time when it reaches the end of the distillatory vessel or chamber nearest the fire. As the distillation proceeds the vapours pass downwards to the space between the rails or rollers and the inclined bed of the distillatory vessel or chamber, and the less volatile vapours are there condensed, and flow downwards to the condensing chamber, where the more volatile vapours are condensed. A large pipe conveys the liquid hydro-carbons from this chamber, together with such more volatile vapours and permanent gases as may still remain uncondensed. The liquid products of the distillation are collected in vessels or tanks, and the uncondensible portions allowed to escape; or the latter may be collected and burned for illuminating or heating purposes.

When it is desired to separate the products of the different stages of the distillation, the patentee introduces sliding partitions at different parts of the distillatory vessel, so as to preserve the products condensed at different parts separate. The said partitions are withdrawn during the moving of the trays.

The zinc plate forming the lower end of the inclined bed of the distillatory vessel or chamber, is introduced as a safety valve in case of explosion. It is made as thin as possible, and communicates with an open space below. The rest of the furnace being strongly built, the said zinc plate on account of the small relative tenacity of zinc gives way in case of explosion, and the gases escape downwards through the opening without injuring the workmen or destroying the furnace.

THE ROYAL SOCIETY.

At a recent meeting of the Royal Society, with Major-General Sabine in the chair, a communication was read "On the Rigidity of the Earth," by Professor William Thomson, F.R.S.

The author proves that unless the solid substance of the earth be on the whole of extremely rigid material, more rigid for instance than steel, it must yield under the tide-generating influence of sun and moon to such an extent as to very sensibly diminish the actual phenomena of the tides, and of precession and nutation. Results of a mathematical theory of the deformation of elastic spheroids, to be communicated to the Royal Society on an early occasion, are used to illustrate this subject. For instance, it is shown that a homogeneous incompressible elastic spheroid of the same mass and volume as the earth would, if of the same rigidity as glass, yield about 7-9ths, or if of the same rigidity as steel, about 2-5ths of the extent that a perfectly fluid globe of the same density would yield to the lunar and solar tide-generating influence. The actual phenomena of tides (that is, the relative motions of a comparatively light liquid flowing over the outer surface of the solid substance of the earth), and the amounts of precession and nutation, would in one case be only 2-9ths, and in the other 3-5ths of the amounts which a perfectly rigid spheroid of the same dimensions, the same figure, the same homogeneous density, would exhibit in the same circumstances. The close agreement with the results of observation presented by the theory of precession and nutation, always hitherto worked out on the supposition that the solid parts of the earth are perfectly rigid, renders it scarcely possible to admit that there can be any such discrepance between them as 3 to 5, and therefore almost necessary to conclude that the earth is on the whole much more rigid than steel. But to make an accurate comparison between theory and observation, as to precession, it is necessary to know the absolute amount of the moment of inertia about some diameter; and from this we are prevented by the ignorance in which we must always be as to the actual law of density in the interior. Hence the author anticipates that the actual deformation of the solid earth by the lunar and solar influence may be more decisively tested by observing the lunar fortnightly and the the solar half-yearly tides.* These tides, it may be supposed, will follow very closely the "equilibrium theory" of Daniel Bernouilli for all oceanic stations, and the author suggests Iceland and Teneriffe as two stations well adapted for the differential observations that would be required.

The earth's upper crust is possibly on the whole as rigid as glass, more probably less than more. But even the imperfect data for judging referred to above, render it certain that the *earth as a whole must be far more rigid than glass*, and probably even more rigid than steel. Hence the interior must be on the whole more rigid, probably many times more rigid, than the upper crust. This is just what, if the whole interior of the earth is solid, might be expected, when the enormous pressure in the interior is considered; but it is utterly inconsistent with the hypothesis held by so many geologists that the earth is a mass of melted matter enclosed in a solid shell of only from 30 to 100 miles thickness. Hence the investigations now brought forward confirm the conclusions arrived at by Mr. Hopkins, that the solid crust of the earth cannot be less than 800 miles thick. The author, indeed, believes it to be extremely improbable that any crust thinner than 2,000 or 2,500 miles could maintain its figure with sufficient rigidity against tide-generating forces of the sun and moon, to allow the phenomena of the ocean tides and of precession and nutation to be as they are.

---

* High tide, as far as the influence of either body is concerned, is produced at the poles, and low (average) water at the equator, when its declination, whether north or south, is greatest, and low water at the poles and high water at the equator, when the disturbing body crosses the plane of the equator.

"On the Difference in the Properties of Hot-rolled and Cold-rolled Malleable Iron, as regards the power of receiving and retaining Induced Magnetism of Subpermanent Character." By George Biddell Airy, Esq., F.R.S., Astronomer Royal.

The author states that he had been desirous of examining whether differences in the degree of change of subpermanent magnetism, such as are exhibited by different iron ships, might not depend on the temperature at which the iron is rolled in the last process of its manufacture. By the good offices of Mr. Fairbairn, he had received gratuitously from Richard Smith, Esq., Superintendent of Lord Dudley's Iron Works at the Round Oak Works, near Dudley, twenty-four plates of iron, each 16 in. long, 4 in. broad, and ¼ in. thick; twelve of which, after having been manufactured with the others in the usual way, had been passed through rollers when quite cold. Each set of twelve was divided into two parcels of six each, one parcel being cut with the length of the bars in the length of extension of the fibres of the iron, the other being cut with the length of the bars transverse to the length of extension.

For experimenting on these, a large wooden frame was prepared, capable of receiving the 24 bars at once, either on a plane transverse to the direction of dip at Greenwich, or on a plane including the direction of dip. In some experiments, these planes are covered with flag-stones, and the bars were laid upon the flag-stones; in others, the bars were laid immediately upon the wood. While there lying, they were struck with iron or wooden hammers of different sizes. The bars of the different classes were systematically intermingled, in such a way that no tendency of the arm to give blows of a different force or kind in special parts of the series could produce a class-error in the result. For examination of the amount of polar magnetism in each bar, it was placed at a definite distance (5 in.) below the prismatic compass, which was used to observe the apparent azimuth of a fixed mark; the bar was then reversed in length, and the observation was repeated in that state.

The number of experiments was 21. They were varied by difference in the succession of positions of bars, difference of time allowed for rest, difference in the violence of the blows, &c.

The principal results appear to be the following:—

1. The greatest amount of magnetism which a bar can receive, appears to be such as will produce (on the average of bars) a compass-deviation of about 11°, the bar being 5 in. below the compass. It was indifferent whether the bars rested on stone or on wood, or whether they were struck with iron or with wood, the bars lying on the dip plane while struck.

2. When the bars, thus charged, lay on the plane transverse to the dip, they lost about one-fifth of their magnetism in one or two days, and lost very little afterwards

3. When the charge of magnetism is smaller than the maximum, the diminution in a day or two is nearly in the same proportion as for the maximum.

4. The effect of violence on the bars, when lying on the plane transverse to the dip, is not in all cases to destroy the magnetism completely; sometimes it increases the magnetism.

5. The cold-rolled iron receives (under similar violence) or parts with (under similar violence) a greater amount of magnetism than the hot-rolled iron, in the proportion of 6 to 5.

6. There is some reason to think that the hot-rolled iron has a greater tendency to retain its primitive magnetism than the cold-rolled iron has.

7. There is some reason to think that, when lying tranquil, the hot-rolled iron loses a larger portion of its magnetism than the cold-rolled iron loses in the same time.

TO CORRESPONDENTS.

The MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to M. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5½d. per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

A. D. (Newcastle).—We do not think that there is any work published on the subject. We will inquire further, and, if successful, will let you know the result in our next number.

T. S. (Manchester).—It is very difficult to get one of these appointments without powerful interest.

L. F. (Bradford).—By sending 1s. 2d. in stamps to Mr. Bennett Woodcroft, Patent-office, Southampton-buildings, London, you can get the specification.

A. P.—The greatest *authenticated* speed on a railway is about 80 miles an hour.

H. M.—We believe that 1,000 cubic feet of gas have about the same heating power as 1 cwt. of coal.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our Correspondents.*]

SUBMARINE TELEGRAPHY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In a letter which appeared in the MECHANICS' MAGAZINE of Feb. 6th, an anonymous correspondent endeavours to show that my proposed scheme of a deep-sea survey, for telegraphic purposes, is visionary and impracticable. Had the writer in question taken the trouble to assure himself of what has really been said or written by me on the subject, instead of relying on "abstracts," for the accuracy of which he must be aware I am in nowise responsible, I should have respected his opinions, however much they may be at variance with my own. But when "An Old Sailor," "for the honour of his cloth," as he pompously intimates, is content to furnish the public with a *rechauffe* of the unsupported assertions of others, to "affirm" this or that, under cover of an *incognito*, and to resort to misinterpretations, which are inexcusable, inasmuch as they were avoidable, no alternative is left me but to expose his weakness.

Taking the sequence of topics as they occur in "An Old Sailor's" letter, I beg to observe that my method of survey, across a two-mile longitudinal belt of the Atlantic, was based on the belief that, wherever "lines of soundings" have been heretofore laid down on our charts, the position of each cast might be depended on. In short, that these lines of soundings are, what they profess to be, *trustworthy, and not falsified records.* I candidly confess such to have been my belief when I projected my scheme; and, what is more, that it shall continue to be my implicit belief until far more weighty evidence is adduced to the contrary than has as yet been made public.

What I did state I repeat, namely, that, under sufficiently skilful management, a steam ship can maintain her position over the point at which a sounding is being taken without drifting so far as to vitiate the observation. But this view is not mine only, although I am in a position to confirm it from personal experience. It is the deliberately expressed opinion of Sir Leopold M'Clintock and Captain Dayman, as I am prepared to show. Consequently the onus of proving it to be impracticable to sound without drifting five, ten, or even fifteen miles during the period occupied in a single operation—as recently asserted by Sir Edward Belcher—rests with him. When he makes good his assertion, it will be time enough to condemn my project, but not till then.

As regards the catechetical mode of testing my knowledge of the methods of taking observations at sea, I have only to say that unknown querists must rest content to have as little value placed on their questions as on their "affirmations" as to whether my plan would "take nearer five or six years to accomplish than as many months."

Your space, Sir, is too valuable, and my time too fully occupied, to admit of my splitting straws, however much time "An Old Sailor" may have to devote to such an accomplishment. But the question he raises hinges on no specious mode of putting the case regarding Lieutenant Sainthill's sounding. In my observations at the Royal Geographical Society, I distinctly pointed out that *some years previously* to the date at which Captain Dayman's 3,000 fathom sounding was taken, Lieutenant Sainthill's cast of 100 fathoms had been reported. So that "An Old Sailor's" acute sensibilities stand him in no good stead, however laudable they may be.

Had Admiral Elliott and Sir Edward Belcher "assured the meeting that all my foraminifera and diatoms were nothing but young oysters," I might certainly have been somewhat surprised; but assuredly not half so much surprised as I was to hear the assertion of the last-named officer with reference to drifting, of which mention has already been made.

To any knowledge of "seamanship" I have not pretended. But I do pretend to an ordinary knowledge of the laws that govern matter; and when I suggest the *buoying up of a light line attached to the telegraphic cable* (instead of supporting the cable itself, as imputed to me), I am constrained to suspect that "An Old Sailor's" pretensions to a like knowledge are questionable—to say the least of it.

The last point of "An Old Sailor's" attack, however, attests the true animus under what his letter was written. He says he is "jealous of the honour of his cloth." Far be it from me to attempt to deny what his language so unequivocally proves without my aid. But he refers me "to the *preface* of Charles Darwin's Naturalist's Journal of the 'Beagle's' voyage" if I wish to see what I have left undone in not acknowledging, in the first part of my work on "The North Atlantic Sea-bed," services rendered me by Sir Leopold McClintock and the other officers of H.M.S. "Bulldog."

Now, I do not know how long your anonymous correspondent may have been "tied to his chair in the country with an attack of gout"—which would appear to have been the primary piece of news he had to communicate to the readers of the MECHANICS' MAGAZINE, seeing that it takes precedence of everything else; but this I do know, that it never has been, and, if I can help it, never shall be, laid to my charge, that I fail to acknowledge kindnesses. And, had "An Old Sailor" allowed me to rest on my oars until the publication of part 2 of my book—the only portion of it in which a preface could be inserted—he would have spared me a little trouble, and himself no little ridicule.

Heartily wishing him a happy deliverance from his only enemies, the spleen and gout, I beg to subscribe myself his and your

Most obedient servant,
G. C. WALLICH.

Kensington, Feb. 7th. 1863.

SIR,—The subject of Transatlantic telegraphic communication being still under consideration it can do no harm for a non-scientific individual to state an idea which has frequently occurred to him, namely, that the cable should be laid in the usual manner, in the comparatively shallow water on either side of the Atlantic, and when (as on the banks of Newfoundland and elsewhere) the soundings are favourable; but that in the intervals of deep waters the cable should be submerged as follows:—That at stated intervals of so many miles, these intervals to be tested by experiment, the cable should be sunk beyond any possible contact with the keels of the largest known vessels, by means of sufficient weights, over which buoys strongly constructed should be placed, having electric communication with the cable. I am not sufficiently scientific to know whether the strain would be too great on so long a line of cable thus suspended, but I do not think it would. Assisted by vessels of all nations, rendezvoused at stated points, the cable might be thus submerged in a couple of summer days. I do not think that stormy weather would strain it beyond what might be guarded against.

Vessels might occasionally damage the buoys, but this would only be a rare accident. In the event of any interruption of communication, the defective portion of the cable might be discovered by experiment to ascertain between which of the buoys the defect lay. In the event of a rupture of the cable itself, the ruptured ends could be traced by following the line of buoys. I have no doubt that buoys at ten or fifteen miles apart would answer the purpose of submersion.

Some of your scientific contributors may be able to prove that such a scheme is impracticable; however, any plan that is not open to the objection to which ordinary submersion is liable, namely, that once damaged the entire cable is lost for ever, is worthy of consideration.

I am, &c.,
Edinburgh, Feb. 10, 1863. I. J.

A similar plan to the above was suggested in our columns by Dr. Wallich, on the 5th of December last.

PATENT LAW REFORM.

Sir,—As the Commission appointed to consider the Patent Laws is sitting, this subject is becoming important. It is to be hoped that practical suggestions will be freely given in the Mechanics' Magazine on this subject. The first thing to be done is to get out a sketch of such proposed rules as may be laid before the public and the Commission. This I hope to be able to do in a few days.

A chief difficulty in settling questions of infringement is the present character of the jury. This is no easy matter to deal with. The best suggestion I can give is, that a *scientific jury* should be appointed in patent causes. Even this is only an approximation towards a satisfactory decision in such cases, but it seems at present the best. What are the views of your readers on this subject? Now, I think, is the time to express them: at least, I humbly so suggest.

Another difficulty in patent causes is the character of the tribunal. At present this description of causes are tried in one of the superior courts of law which have co-ordinate jurisdiction. Justice Cockburn has lately, as is well known, somewhat set his face against the trial of such causes. This is not to be wondered at, considering the general complexity which besets the evidence. In addition to this, patent causes take, generally speaking, more time than other causes, and they frequently hinder the trial of commercial actions. There is, I believe, a growing desire for a Patent Law Court, to be presided over by a judge who shall devote his time and attention *exclusively* to this branch of jurisprudence. Now, what is the opinion of your readers as to this?

Other matters relating to "specifications," "letters patent," and "disclaimer," I shall have presently to lay before your readers. The machinery of a patent, though decidedly improved by the Act of 1852, admits, I think, of further improvements. There is, I find, a growing disapproval of the restrictions on trade which are the results of patents, and this fact should not, I suggest, be overlooked by inventors. No doubt "monopolies" somewhat "clash" with *moral* rules, and furnish instances of opposition between the laws of this country. This being so, we cannot wonder that Bentham had, as I believe is the fact, serious doubts as to the continuance of monopolies in England. These hints I throw out *suggestively* and *significantly* for the consideration of your readers. It follows, I think, that "too much" must not be expected from the Legislature, and the duties of the present session of Parliament will not, I fear, admit of the consideration of "nice questions" in such a subject as this.

I am, &c.,
J. Culverhouse.
3, Compton-street, Ballspond,
6th Jan., 1863.

PATENT LAW.

Sir,—The recent extraordinary trial of Clare against the Admiralty has given the *Times* an opportunity to renew its hostility to inventors generally. Its remarks, in a leading article on Saturday last, were pertinent enough as far as concerned Mr. Clare's claims, but the attack on all inventors was as unjust as it was absurd, though I do not think there is any danger of the opinions of the *Times* having any weight with the parties entrusted with the consideration of the patent laws.

I will attempt to define an invention. The world is on the road from ignorance to wisdom; every improvement in any mode of accomplishing any object, every increase of economy in time, labour, or materials, is a step forward on this road from ignorance to wisdom, and the person who performs it is as much entitled to be rewarded as he who writes an article for the *Times*, or builds a house, or parts with a field. Invention being the fruit of his labour, it is his property, and if his fellow men avail themselves of the facilities afforded for robbing him of this kind of property, without remunerating him, they are quite as dishonest as the housebreaker who steals your goods.

Suppose an enterprising man to set up a printing establishment, and at the earliest possible moment every morning to get some copies of the *Times*, distribute them among his compositors, and in an hour or two print off some thousands of copies of the *Times* (without the advertisements) and sell them at one penny each. What would the proprietors of the leading journal say to this? Would they call it just? Yet this would be no more unjust than what they propose to do with patentees, viz.: the sweeping away of all protection.

But the *Times* proposes to reward deserving inventors by public grants! Shade of Cort, arise! What a Will-o'-the-wisp for a genius to pursue. How poetic, to invent and starve, and probably when the next generation arises, to have one's name mentioned as a fit subject for a monument in a niche in a public building.

What we want, Mr. Editor, is good and cheap protection for really good inventions, with a chance of getting some reward before the heavy sums become payable, and a ready means of quashing trumpery claims to invention.

There is, however, one want which I have long felt should be supplied. A man invents something useful in his trade, and is willing to give it to the world; but the moment he publishes it, some other person, who has a six months' provisional protection running, with a sufficiently comprehensive title, immediately adopts the unprotected invention, inserts it in his complete specification, and stops the real inventor from using his own invention without a license from the purloiner.

To meet this, and cases of a similar character, I would have a class of patents to be called "Public Patents," the entire office fees to be one guinea only, and the patent immediately to belong to the world. It is true the same thing may be done at present by abandoning a provisional protection, but this is at the heavy expense—including agent's fees—of £10, and the title "abandoned" is ugly. I think if this class of "Public Patents" is established it will be productive of much good, and prevent many speculative and mischievous patents from being granted, besides taking away some of the false arguments used by the opponents of protection.

I am, &c.,
1, Clifford's Inn, Feb. 9, 1863. T. Moy.

WHITWORTH PROJECTILES.

Sir,—Dazzled by the brilliancy of the success obtained by Mr. Whitworth with his steel shot, in overcoming the resistance of iron plates, the authorities seem to have been unable to perceive the conclusion rightly to be derived from it. They appear to attach some mystic importance to the method of rifling, and the form adopted for the shot—an importance which is neither born out by the result of experiments, or by the investigations of theory.

The direction which Mr. Whitworth's success indicates that we should take, in order to arrive at increased efficiency of artillery fire in penetrating iron, lies simply in the employment of shot composed of very hard and tenacious metal, and moving at high velocities.

The nature of the grooving in the bore of the gun, by which the shot's rotation is enforced, is, no doubt, a matter concerning which the plate impinged on is profoundly indifferent; while the explanation by which it has been usually sought to prove the superiority of the flat over the round fronted shot, is far from being incontrovertible. A more probable theory might be advanced to show cause for the superiority of the flat front, when the metal composing the shot is comparatively soft, as has been the case in all experiments where any superiority was manifested by the "flat heads."

It may, I think, be safely asserted that, with shot composed of the hard and tenacions metal adopted by Mr. Whitworth, the result of their impact will not be materially affected, either by rifling or by peculiarity of form; and I venture to assert that a "68"-pounder shot, composed of the Whitworth steel, and projected with the usual velocity from a 68-pounder gun, will, at a range of 200 yards, penetrate the "Warrior" target.

I am, &c.,
Feb. 10th, 1863. Iron.

"FUNICULAR" ACTION.

Sir,—As you have favoured me on a former occasion with a space in your columns on the score of humanity, I again venture in the same strain, for it is quite lamentable to read of the many deplorable accidents with such sacrifice of life, limb, and property; and I feel assured that if you, and some of your scientific readers, will give your powerful aid to the subject, a check will be given for the future to such as may be considered "mechanical accidents."

Soon after the disaster at Notting-hill, I went and saw the fallen arches, and it brought to my mind the occurrence at the South Lambeth Waterworks, an account of which is in Vol. 62, page 558, Mechanics' Magazine.

Shortly after that mishap I read somewhere a letter from a continental correspondent, which stated that the English architects did not thoroughly understand such work. When, lo! in the following June, a wholesale affair occurred at the new waterworks at Brussels, see Vol. 63, page 85, Mechanics' Magazine. So that the English did not stand quite alone at that time.

My meaning for using the term mechanical accidents, is for such as might possibly be foreseen by those who have a good knowledge of mechanical action. I became a little more acquainted with it as follows:—During the time of the building the station at King's-cross, I was much interested by seeing the compassed wooden girders put up to form the building, and as it approached something like completion, I was quite at a loss, after walking around the place several times, to know why the wall in Maiden-lane, and the inner piers adjacent, should not yield to the pressure?

Just at that time I was an eye witness to some experiments going on with some arches, constructed with brick and cement, being loaded with iron till they fell; and as I could not glean anything from the person who superintended the work and the loading, I set to, and cubed some of the debris, crushed them by leverage, and made a small apparatus for evening amusement, with which I treated arches as triangles, and could tell to a little what was the lateral thrust with a given load on the arch. I then made a drawing like an arch of the King's-cross station, with the following remark:—A lever of the fourth order, a simple instrument for throwing down a wall.

A little time elapsed, when of a sudden there was great bustle at the said station; the wall and inner piers were yielding on the Maiden-lane side: abutments were strengthened, wooden frame-work put in lieu of brick arches; and so it remains to this day.

A few years rolled on, when I procured a work brought out in 1837, by Mr. Adams, on English pleasure carriages, in which it states:—"An authority of high repute, Mr. John Farey, author of the well-known work on the steam-engine, has added to the ancient catalogue of the 'mechanical powers' two others, viz.: 'The Funicular Action,' 'The Hydrostatical Action.'

After duly considering the said "Funicular Action," of its probable connection with past accidents, and possibly with accidents to come, I wrote the following:—"Funicular Action, mentioned at page 63, should be well understood by a coroner; he would be then able to solve the query,—Why a chain that will sustain a weight of ten tons appears to fail with the weight of one ton, scaffolds fall, bridges, &c., &c." If I had been a little more liberal I might have added architects, engineers, surveyors, and others, superintending mechanical works of any kind.

The word funicular is seldom seen or thought of. It was to be seen in the western annex of the Exhibition of the past year,—"An Austrian Locomotive."

That the said action has a great deal to do with accidents I feel quite certain; and, with a better knowledge, some of the following cases possibly could have been avoided:—

Scaffold at St. Martin's-hall; scaffold under the bridge on the Thames; stone at King's-college; another at the Victoria-docks; the bridges at York and Harrowgate; the gun at the steam crane at Woolwich, in frosty weather; fall of a fly-wheel on a person at Ballspond; girder at the Crystal-palace; the almost accident to a female Blondin, when the side rope or ropes broke; the breaking of a copper wire which let a female Blondin down in the pit of a theatre—it was said the copper was bad; English Blondin at Shields, when a boy was killed by the falling of poles, or shear legs; Blondin with his man on his shoulders, when they fell in the laps of the audience in the gallery—the railing gave way; the female Blondin and man of colour at Northfleet, by the breaking of one shear leg; wall and piers at King's-cross station; arches at Brixton, at Brussels, at Cotton's-wharf, and many others that have actually fallen, apparently without rhyme or reason; of the pier that sunk at Notting-hill, and likewise at Clapham, there is no foundation to say the cause was "funicular action," or a triangle of forces; but the arches that fell in consequence were! and so was the Fleet-ditch; for I consider it to have as much to do with the ditch as with the telegraph wire which broke and killed one person on Blackfriars-bridge, and injured another.

There is an amount of pressure or strain that seems to escape consideration.

Not long since there was a fatal case on a portion of the North-Western line, when Gardener, the brakesman, was killed; and, I doubt very much whether that would have happened, if the said action had been but little understood by those who had to right the carriages.

I once saw a large boiler let down to its bed with strong scaffold poles for shear legs, and pulleys, &c.; a guy rope was attached to one pole, some three or four feet above where the poles crossed each other, and was secured somewhere at a right angle; when the weight was getting heavily on the legs, the one pole bent so much, and the guy rope stretched so enormously, that a fresh start was required. Had the guy rope been fixed at an angle of 45 deg. instead of a right angle, a much less weight would have had the same effect; and, if the materials used had not been of the best description, down she must have gone. The following experiments and questions seem to be in one way or the other connected with the aforesaid cases:—

If a pound weight be suspended from the centre of a bar by a string, or wooden slip, it is clearly seen that there is a strain of one pound on the bar. "The weight of the material is not considered." The result is the same if the slip and the weight are placed above the bar. Now, if the said bar is half-inch square, and rests on bearings two feet apart, the strain on the under side of the bar "by the weight" is several pounds, and the compression on the upper side is to the same extent. With two slips of wood, each 12 in. long, which are to be used between two piers, one pier is provided with a weighing machine, to ascertain the lateral pressure, the other pier is moveable, to make the slips form any angle required; one end of each slip rests on a pier; the other ends meet at a point. When the slips are loaded, there is not only an aditional vertical weight on the piers, but a lateral thrust, which "force in a building" would act on a tie rod if placed there; if without a tie rod, and the material is not thoroughly set, and the piers of sufficient weight and base, they will yield; and then down goes the mass.

If two uprights, with a pulley on the top of each, are placed three feet apart, and a line passed over both, with a provision at each end of the line to receive weights: any weight hung on the horizontal part of the line, "at any point," will give an amount of strain to the line, which will be indicated by the amount required on the vertical parts of the line, to bring the line between the uprights to any required angle.

Two piers ten feet apart, between which is built with cement an arch of one brick thick, 4½ in. by 9 in., the spring 4 in—what weight fairly laid on will crush it? What will be the pressure against the piers, at the crushing point?

With a wire one-eighth of an inch in diameter, capable of sustaining a weight of 1,000lbs. vertically, and two uprights 12 ft. high, and 300 yards apart, with a guy wire to each, fastened at top, and 3 ft. from the base. It is required that the wire shall be fastened to the top of uprights, with a 14 lbs. weight, hung on the centre; and the wire at centre must only deflect 9 in. What will be the strain on the wire; and what on the guys; will the 14 lbs. break the wire? What will be the vertical pressure on the uprights? When fixing the wire, should it be payed out from a revolving reel, and partially straightened as it leaves? Or taken from a coil, and be in a high state of torsion, when stretched? Less mischief would occur from the former than the latter.

If a piece of work had to be placed in position, the weight of which is 16 cwt., and there happens to be some obstacle in the way, so that the slings must be kept extremely low; if the slings form an angle of 5 deg. from the lifting hook to the bearings on the load, each half would have to sustain a weight equal to about 5 tons 12 cwt., and yet be calculated to carry a load of only 1 ton 5 cwt. If the angle was—

		Tons.	Cwt.	
10 deg.	the load would	= 2	8	each.
20 deg.	,,	= 1	4	,,
30 deg.	,,	= 0	16	,,
45 deg.	,,	= 0	12	,,
90 deg.	,,	= 0	8	,,

It is really surprising that disaster is not more frequent, for the said action is synonymous in respect of arches, truss girders, slings, &c.

And now I must leave the subject to a more cultivated mind, and apologise for the intrusion.

I am, &c.,

Feb. 1, 1863. G. B.

ON GRAVITY ESCAPEMENTS FOR CLOCKS.

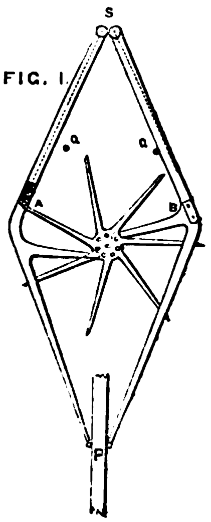
Sir,—About ten years ago you published an account, from the Cambridge Philosophical Transactions, of the gravity escapement which I invented for the purpose of enabling a clock for Fredericton Cathedral to go properly in a temperature cold enough to freeze mercury. That, and some other forms of the same invention, have now been used long enough and extensively enough to afford more complete means of estimating their fitness for different kinds of clocks than existed when the fourth edition of the "Rudimentary Treatise on Clocks, Watches, and Bells" was published, or the short appendix to it two years ago.

I need hardly explain to any one who is likely to read this, that the distinction between gravity or remontoire escapements and others is, that in the common ones the pendulum receives its impulse directly from the clock, and the impulse therefore varies with the state of the clock, the action of wind and snow on the hands, and other disturbing causes; while in gravity escapements the clock only lifts small weights called pallets through some definite space corresponding to a small angle of the pendulum's vibration; after they are so lifted, the pendulum takes them up alternately, and carries them with it as far as it goes, and then they fall again with it, but to a lower point than where they were taken up; and so the difference between their rise and fall with the pendulum constitutes the impulse, which is (or should be) constant and independent of all variations of force in the clock. Moreover, the pendulum has always, in some way or other, to unlock the scape-wheel, which is locked at every beat by one of its teeth resting on stops fixed to the pallets, or some equivalent arrangement; and it is essential that the friction of this unlocking, or rather any possible variation of it, should be so small as to be insensible to the pendulum. And it is still more essential that the scape-wheel should not be liable, in any possible natural state of the clock, to *trip*, *i.e.*, to jerk away the pallet it is lifting, so that several teeth pass at once; nor even to hold up the pallet higher than the proper point for the pendulum to take it up.

I am not going to write here on gravity escapements in general, most of which have so unquestionably failed in some of the above conditions as to throw suspicion on them all; and Mr. Airy's well-known mathematical "demonstration" of the impossibility of their succeeding naturally increased it, till the fallacy of that demonstration was discovered by a barrister, the late Mr. J. M. Bloxam, and also practically refuted, both by his gravity escapement and by several forms of mine, as Mr. Airy himself has acknowledged. The only two classes of escapements that I have to treat of now, are those which have the common property of a scape-wheel with a few long teeth for locking, and a few very short ones, or pins near the centre, for lifting the pallets; but subdivided into those which have a large enough motion at each beat to admit of being controlled by a fan-fly on the arbor of the wheel, and those which have not. The latter class is represented by Mr. Bloxam's nine-legged escapement; the former, I believe it has never been denied, are mine. Both on account of the number of the teeth and priority of date, I will begin with Mr. Bloxam's; but as a figure of that is given in the "Rudimentary Treatise" (p. 124), and I do not want to repeat what may be found there, I will give here a seven-legged escapement on the same principle, which will serve to illustrate them both.

The pallets A S, B S, in all these escapements, are placed on the principle of the one which is struck upwards, A S, making a right angle with the tooth which then rests upon it; and in all but Fig 3, the other pallet B S does the same when it is lifted. The wheels all turn to the right, and all the pendulums P are at this moment moving to the left, and just going to lift that pallet, A S. The theoretical centre of the pallets S, is at the top or bend of the pendulum spring; the actual pivots and arbors are as close by the side of S as they can be placed, so that there is no sensible friction at P. Q Q are banking pins for the pallet to rest against, without pressing on the lifting pins when they are down, so that the clock may more easily begin to lift; just as the striking wheel of a common house clock generally requires to have a little run at the hammer tail before the pins begin to lift it. The distance of centres of the wheel and pallets we will call d throughout; and the distance of the faces of the stops from S, or the length of the pallets, p, and the radius of the scapewheel r.

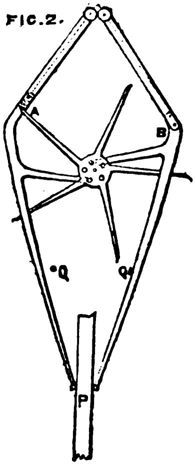
FIG. 1.



In the seven-legged escapement you will find that $d = 2{\cdot}24r$, and $p = 2r$; in the nine-legged $d = 3r$, and $p = 2{\cdot}28r$. The pressure and friction on the stops decreases with the number of the teeth, though not quite in that ratio, because this pressure is partly relieved by that of the pallets upon the wheel through the lifting pins. Therefore, both on this ground and the proportions between p and r, the friction of unlocking will affect the pendulum more in the nine legs than the seven. Mr. Bloxam, no doubt, had some reason for preferring the nine, but I do not know what it was. His own clock performed very well, but it required such delicate work, and such a fine train of wheels, that I believe no second specimen has been ever made, unless we are to except a small turret clock, which was stated to be got up for the late Exhibition under the superintendence of Mr. Airy, but was withdrawn before it had been there a fortnight, and not too soon. I do not know that the seven-legged escapement has ever been tried, nor do I suppose that it would differ so materially from the nine, as to be fit for ordinary use.

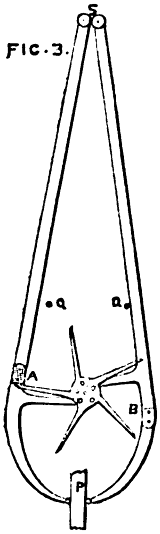
The next in numerical order is a five-legged escapement on the same principle, of which Fig 2 will give a sufficient explanation. The pallets are now still shorter, p being $= 1{\cdot}37r$, and $d = 1{\cdot}73r$; and the motion of the wheel is so much greater, that the velocity can be controlled by putting a fly of moderate size on the arbor, which was first done in my three-legged escapement in 1852. But still the fly, unless it is very large, is not enough resisted by the air to make this escapement safe from tripping in large clocks, where there must generally be a considerable surplus force to make sure of driving the train and hands in all weathers, temperatures, and states of the oil. For that reason we rejected it for the Westminster clock, though it is more tempting in appearance than some others which are superior to it in reality. Even a four-legged escapement, where of course the fly has more control, was found not safe

FIG. 2.



enough, and was changed into another form of three legs, which I shall speak of presently. I have seen this five-legged escapement with short pallets, apparently acting well enough in a small clock, of the common domestic size, though even for that I think the four-legged escapement better, on account of the greater control by the fly, and its requiring less careful work and adjustment.

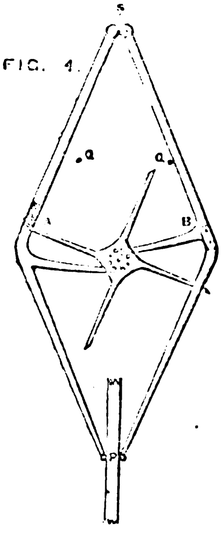
FIG. 3.



The five-legged escapement has been made (but under no advice of mine) in another form, corresponding to that of the original three-legs, for which this figure (3) will serve as well, if you assume the teeth to be 120° apart instead of 72°. Instead of the pallets embracing one tooth-space less than half the wheel, as in all the previous escapements, the stops are now opposite the ends of a nearly horizontal diameter; the up stop A being rather above the centre, in order that that pallet may make a right angle with the tooth, or it will trip; and the down stop B as much below, because if it is not, the beats will be unequal; but, on the other hand, if it is much below the level of the up stop, the unlocking will have a scraping action, which increases the friction, already large enough. For this construction requires the pallets to be very much longer in proportion to the wheel than in the other escapements, and therefore the effect of the friction at unlocking is so much greater on the pendulum: d and p can hardly be less than $= 6r$. And the pallets, hanging nearly vertical, have a greater dead weight resisting the pendulum at each impact in proportion to their effective weight required for the impulse; and this diminishes the arc; and the errors of every escapement vary inversely as the cube of the arc (other things being equal). The same position and momentum of the pallets also increase their liability to trip, even with a three-legged wheel; and a five-legged one is quite unsafe, except with a fly of inconvenient size, and the pressure on the stops is still greater. Therefore, the three-legs in its original form is imperfect, and a five-legs with long pallets is by far the worst of all this class of gravity escapements.

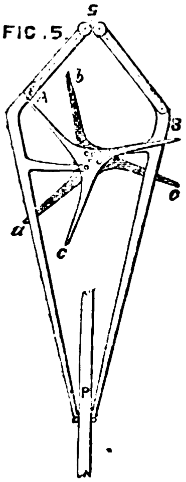
Some of its defects may certainly be met by the addition of a train remontoire, to cut off the variations of force before they reach the scape-wheel, as was done in the clocks with this escapement in the Exhibition. But that is only making two remontoires in the same clock, which is well enough for making a show of elaborate machinery, but is exactly the opposite of the true object of all scientific improvements, to produce better effects with simpler machinery. To say that a remontoire escapement will answer if another remontoire is added, is to confess that it fails in the primary conditions of such an escapement, and is, in fact, useless; for a dead escapement, kept clean and oiled, with the help of a good train remontoire, not encumbered with unnecessary friction, will go as well as any gravity escapement. One of the chief objects of these fly gravity escapements was to get rid of the necessity for train remontoires in large clocks required to go accurately; for they are not only rather expensive, in their cheapest form, but by no means safe things to leave in the hands of such persons as usually have the care of turret clocks. I have known two deliberately destroyed, probably because the workmen had put them wrong, and could not put them right again.

FIG. 4.



All the escapements hitherto described have an odd number of teeth; and so they must if all the lifting pins are on one side of the wheel; for the pin which has just lifted its pallet must be as much in advance of the vertical diameter as the pin that is going to lift is behind it. But a four-legged wheel will do as well, if you have two sets of pins, four of them pointing forwards, and acting on one pallet B, which stands before the wheel, and four others in intermediate places, acting on the other pallet A, behind the wheel. The stops also are on opposite sides, the B stop behind its pallet, and the A before it. This too has the incidental advantage of letting the pallet arbors go closer together at S. Here $d = 2·6r$, and $p = 2·4r$, which are convenient sizes for a wheel of 1¼ in. radius, and a clock of the usual regulator size. The pins in a wheel of this size should be one-eighth of an inch from the centre, to produce the proper lift. The motion at each beat, 45°, gives the fly quite sufficient control for any possible variation of force and risk of tripping in a small clock, though hardly in a large one. The fly should be as light as possible, and is best made of aluminium, or at least of very thin steel. Other details of construction and arrangement of the train for this escapement will be found in the "Rudimentary Treatise," but I had not then sufficient experience to be able to speak of its performance. I can now say, from other experience besides my own, that it answers extremely well in regulators, and in one respect better than the double three-legs (to be described presently), which is superior to this for large clocks. For when the scape-wheel turns in only six seconds, its pinion has to be so small that more force is lost in friction than any one would imagine who has not tried it. The weight of the double wheel also wastes some force in a small clock. I know two clocks which have been altered from the original three-legs to this, and they now drive a pendulum of 40 lbs. with a smaller weight than they required before for one of 15 lbs. This escapement requires no delicacy of construction, and pinions of 10 are quite sufficient, when they are good ones. Mine had to be sent back three times to Clerkenwell, before we could get a train fit to use. Such is (or was in 1861) clock-making machinery in London.

FIG. 5.



The defects which I have mentioned in the single three-legs (though I hear of some of these clocks going wonderfully well) are all removed by setting two scape-wheels on the arbor, far enough apart for the pallets to lie between them. The three lifting pins are also between, rivetted into both wheels. The stop on one pallet is in front of it, to catch the forward wheel, and the other behind to catch the back wheel. A full description of this escapement is given in in the "Rudimentary Treatise," as it was made for the Westminster and Leeds Town Hall clocks three years ago, and since in many others; so I shall not repeat it here. It must be observed that it has one quality distinct from all the other escapements, viz., that you may make p the length of the pallets, and therefore the resistence to unlocking, as small as you please, because the relative position of the wheels is arbitrary. If they are placed with their teeth equi-distant, or 60° apart, as at p. 134 of the "Rudimentary Treatise" (which is, on the whole, perhaps the best arrangement), d evidently $= 2r$ and $p = 1·73r$. In this drawing the teeth $a\ b\ c$ of the following wheel are set 90° behind those of the leading wheel A B C, and therefore $p = r$ and $d = 1·42r$. The pins must always be so set that the two nearest to the locking tooth are on a vertical line, and the third on a level with the centre, and they should not be farther from the centre than about $\frac{d}{40}$, which is a reason against making d very small. In turret clocks, with 5ft. pendulums, the scape-wheels are generally made of 3 in. radius, increasing up to 5 for 13 ft. pendulums. The pressure or friction on the steps is so small that, in the Westminster clock, driving about two tons of dial work and pendulum, no difference at all could be measured in some little weights hung by a thread, so as just to lift the pallets, whether the wheel was pressing on them or not. If it had a dead escapement of the usual kind, the pressure on the pallets would be at least 4 lbs.

I should have thought it superfluous to mention that the faces of the stops should be made flat or dead to the teeth, or at the most, only sloped enough to counterbalance the friction (which is almost less than you can see) if I had not seen some of these gravity escapement clocks made with rounded stops; which just defeats the primary condition of a gravity escapement, inasmuch as it allows the wheel to give an impulse to the pallet, while the pendulum is lifting it. I have put no banking pins for the pallets in this escapement, because it is only intended for large clocks, which have always a superfluity of force arriving at the escapement, beyond what will merely lift the pallets. This escapement has also been accidentally proved to have an advantage which I did not expect: the fly springs had been left loose after some alteration of one of the largest of these clocks, so that the fly was really doing nothing for it; and yet when it was next looked at it was found to have gone correctly without ever tripping. Not that I recommend the omission of the fly, although it is satisfactory to know that no harm will be done if it should get loose by neglect; for every remontoire, either in the escapement or the train, has an unpleasant bang without one, which is always tending to knock the machine to pieces. The secret may now be let out, that the original gravity train remontoire of the Royal Exchange clock, so highly commended by Mr. Airy in a published report, was quietly tied up for several years, on account of the concussion which it caused, until the late Mr. Dent replaced it, at his own expense, with the spring and fly remontoire, like that in his 1851 Exhibition clock, now at the King's Cross Station, of which the rate has never yet been excelled.

Several plans have been proposed for unlocking the wheel by the falling instead of the rising pallet, for the purpose of making it more secure against tripping. The neatest of them is that of turning the points of the teeth sideways, so as to let the stops slide away under them. But when you have once got an escapement absolutely safe from tripping in any possible state of the clock, it is hardly worth while to alter it into one rather more troublesome to construct, for the merely theoretical advantage of making it safer still. If this were all, to be sure nobody could object to it; but it is not all by a great deal; for if you unlock by the falling pallet, you will have the friction on the stops acting, not merely through a very short arc, and in one direction only, but first forwards and then backwards, through a large portion of the whole swing of the pendulum, both up and down; in fact, exactly corresponding to the dead friction in a dead escapement. I cannot help suspecting that all the proposers of these plans (and the principle of them is much older than this class of gravity escapements) have forgotten that the pendulum feels any friction on the pallets quite as much while they are driving it, as while it is lifting them, and that the pendulum really does the unlocking quite as much in one case as the other, but on their plan with all this extra friction into the bargain. As if that were not enough, in one of these clocks, which was exhibited, the pallet centres were put at a considerable distance both from the line and the top of the pendulum, which just introduces another friction between the pendulum and the pallets, which is carefully avoided in every other escapement in the world. I cannot conceive for what object that was done, except to give an appearance of originality, for which adopting a plan rejected by everybody else is not a bad *recipe*. For the same reason, I suppose, the fly was omitted, at the cost of a recoil which seemed to thrill all through the clock. Possibly too, the same explanation may account for that strange adoption of the worst kind of five-legged escapement, by an exhibitor of some very well-made clocks in other respects, from whom I have a letter saying, he considers the double three-legs "the *ne plus ultra* of escapements." But that was sure to be exhibited by other people, and was already well known as the escapement of the Westminster and other great clocks.

It may be convenient to some readers to have a summary of this review of these different forms of the gravity escapement.

1. The nine-legs and seven-legs are unfit for common use, on account of the delicacy of construction and uniformity of force which they require; and a fly can help them very little.

2. The five-legs with short pallets (Fig. 2) admits of being controlled by a fly sufficiently for small clocks with little friction in the train; but it is less so than the four-legs, and requires more careful construction.

3. The five-legs with long pallets (Fig. 3) is in every respect the worst of all the fly gravity escapements; having the greatest friction at unlocking, the least control by the fly, the most liability to trip, and the dead weight of the pallets and their resistance to the pendulum not exceeded in any other escapement.

4. The single three-legs is open to some of the same objections, though by no means to the same extent.

5. The four-legs is probably on the whole the best for small clocks, and certainly acts very well in them, and keeps an unusually steady rate; but it is hardly safe for large ones, without a fly of inconvenient size.

6. The double three-legs, made as described here or in the "Rudimentary Treatise," or in any proportion between those, is decidedly the best of all for large clocks, having the least friction, the greatest control by the fly, and being safe even if the fly should fail, and requiring the least delicacy of construction; in fact, much less than a dead escapement. It is now used almost exclusively by some of the best makers of turret clocks; and therefore anybody who chooses to require it can do so without losing the benefit of competition. Or, if people would only stipulate that their clocks are not to be fully paid for until they have gone six months, without ever varying more than five seconds a week, which is more than they ought to vary (not 5 minutes, as I saw in an absurd specification lately, fit for 150 years ago), that and the competition in price would soon settle what escapement is to be adopted by clockmakers who still refuse to alter their old patterns, or who make clocks as if they had steam engines to drive them.

These remarks are written for the information of those who like to avail themselves of it, and not to introduce a controversy, as letters on horology generally do: if anybody else introduces it, I shall not follow him. To any one who wants further information, beyond what is contained here and in the book referred to, I shall be glad to give it whenever I have time.

I am, &c.,
E. B. Denison.

33, Queen Anne-street, Feb. 2, 1863.

PHOTO-ZINCOGRAPHY.

Sir,—My attention has been directed to a review of Capt. Scott's work on Photo-Zincography, in your number of the 23rd ult., wherein you state that I am reproducing the first folio edition of Shakspeare's plays at the Ordnance Survey Office. This statement is not strictly correct. It is true that I have expended a great deal of time and a considerable sum of money in endeavouring to reproduce the folio in question, by photo-zincography, at the Ordnance Survey Office. But having been denied permission to exercise the personal supervision of the work, which is essential to its accuracy I have withdrawn it from that establishment altogether.

I am, &c.,
Howard Staunton.

Gossip.

New Iron Sheers in the Southampton Docks.—A number of gentlemen, including the chairman and other directors of the company, assembled in the Southampton Docks yesterday (Wednesday) afternoon, for the purpose of witnessing the tests applied to the monster iron sheers just erected for the company under contract, by Messrs. Day and Co., of the Northam iron works. They are of the following dimensions:—Length of the front legs, 110 ft.; length of the back leg, 140 ft; power of the engine to work them, 20-horse power; proof strains to be 100 tons vertical lift, and 80 tons with an overhang of 35 feet from the dock wall. The whole of this work has been successfully carried out under the superintendence of Mr. Alfred Giles, the Dock Company's engineer. The enormous bundles of rail iron, forming the testing weights of 100 tons, were raised from the railway trucks, which run under the sheers, and deposited on the quay; after which 80 tons were lifted and run out 35 ft. from the dock wall, and brought back again in a remarkably quick and satisfactory manner. This is effected by an improvement introduced by Mr. Thomas Summers, of the above-named works, in the construction of sheer-legs, which renders them simpler and easier to work than those on the ordinary plan. In the new sheers the back leg is made to act both as a prop and a guy to the front legs, and its bottom end slides in an iron groove strongly bolted to its foundation. The movement of the back leg along this groove is effected by a powerful wrought-iron screw, 43 ft. long and 8 in. diameter, and worked by the same steam-engine as is used to work the hoisting gear. The length of the groove is 48 ft., and the sheers are run either in or out in about four minutes. The rate of hoisting for weights up to 20 tons is about 12 ft. per minute, and for heavier weights a more powerful purchase is used, giving a rate of from four to six feet per minute. It is believed that no direct lift of 100 tons has ever been made before by one apparatus.—*Times.*

Compressed air in shells is about to receive a trial at Chatham. The elasticity of compressed air augmented by heat, as in concussion, is said to be awfully explosive. It is, if we remember rightly, the cause of earthquakes in all tropical climates.

Mr. James Bruce writes to say that the deficiency of fresh leaves, the only *remora* that impedes the noble enterprise of rearing silkworms, may be obviated by steeping sheets of paper in infusions and decoctions of the mulberry seeds, bark, stems, roots, &c., with the addition of a little gum to preserve them. These insects devour them as greedily as the fresh leaves. Mr. Bruce adds that the *Great Sea Mussel* forms a thread more valuable than silk itself, of which the *Sicilians* formerly made stuffs of incomparable beauty, a secret now forgotten.

Ventilation of Apartments.—The Academy of Sciences, Paris, has received an interesting paper by General Morin, on the ventilation produced in apartments by fire-places. The room of the director of the Conservatoire des Arts et Metiers was chosen by him for his experiments. This room may be heated at pleasure, either by a fire in the fire-place, or by a mouth of the calorifere of the establishment. Experiments were first instituted to ascertain the volume of air evacuated by the fire-place by the mere action of the difference of temperature of the outer and inner atmosphere. This natural ventilation was found to be on an average 400 cubic metres of air per hour, when the outer temperature was between 1·8 and 10 deg. centigrade (35·3 and 50 Fahr.), and the inner temperature was between 18 and 22 deg. centigrade (64·4 and 71·6 Fahr.). Hence this room is sufficiently ventilated by the mere aspiration of the chimney, even when, instead of one person, it contains, as it sometimes happens, ten or twelve. Direct experiments afterwards showed that the mouth of the calorifere introduced 150 cubic metres of air at 20 deg. centigrade per hour (68 Fahr.), when the temperature of the calorifere was between 70 and 100 deg. centigrade (158 and 212 Fahr.); but when the temperature of the calorifere was 45 deg., it only furnished 123 cubic metres. The quantity of air thus introduced through the interstices of two windows and two doors was found to be 246 cubic metres per hour. The fire-place drew from 1,200 to 1,300 cubic metres of air per hour, the amount of wood consumed being 8·26 kilogrammes per hour. The same quantity of air was drawn when the fire consisted of coal, the quantity burnt being 4 kilogrammes per hour. From these experiments it appears that nearly the whole of the warmth produced by combustibles in an apartment is carried off through the chimney, and the only useful part of it is obtained by radiation.

Bees.—The *Agriculteur* contains the following remarks on these singular insects:—Bees do not pass the winter in a state of stupefaction, nor do they sleep much longer during that season than in any other; all that depends upon the work they have to do. There are at all seasons some working bees alive and active in a hive, and at the same time when provisions are being got in, there are many at work day and night without taking any sleep at all. Their slumber is very light at all times, for they sleep with their eyes open; the slightest noise, a vivid light, or a current of air, is enough to awaken them; but the warmer the hive is the easier it is for them to sleep. Hence they consume much less honey in a hive situated in a quiet place, little exposed to light and air, than to one more exposed. But if the outer temperature rises very high, this favours the laying of their eggs, and then a larger quantity of honey is consumed. It is, therefore, easy to explain why in bee hives placed close to each other the consumption of honey is different during winter; and this is a circumstance not to be neglected, because colonies, which before winter seemed to have provisions enough to last them all through the month of March, may be reduced to extremities before the month of January, in which case the apiculturist must come to their assistsnce. If the bees have been able to enjoy an excursion or two since Christmas they will easily partake of the liquid food which may be offered them in a cup placed inside the hive; but if not, the food so administered may cause dysentery. To avoid this honeycombs full of honey should be cut out of other hives where the supply is plentiful, and transplanted into the needy ones. This delicate operation is performed in a cellar, by the light of a lantern, and with the aid of smoke. The colonies thus assisted must be left in the cellar, if it be not too damp, until a fine day comes, to allow of their flying out a little. The hives from which the honeycombs have been taken must also be left in the cellar for twenty-four hours at least, during which the bees feed on the honey that has exuded during the operation.

Mr. William Camper, the eminent ship and yacht builder, of Southamptom, has disposed of his business to Mr. Benjamin Nicholson, who has acted as foreman to him for a number of years.

An application has been received by the Mersey Docks and Harbour Board from the Private Telegraph Company for permission to construct two towers, one on either side of the Mersey, for the conveyance of the telegraphic cable across the river; the board to have the use of two wires, on consideration of the company being allowed to conduct their wires along certain parts of the dock estate.

The report of the Clifton Suspension Bridge Company states that the obstacles to the commencement of the bridge having been overcome, operations have commenced, and will be vigorously prosecuted. In accordance with the agreement with the Charing-cross Railway Company, the first instalment of £2,500 for the chains and other ironwork of the Hungerford-bridge has been paid and possession taken. The chains are now being unlinked, and will in due course be transported to Clifton. The report of Messrs. Hawkshaw and Barlow, the engineers, states that the preliminary operations at Clifton were commenced in November last. The preparation of the scaffolding and suspended platform at Clifton, and the manufacture of the additional chains, will proceed while the chains from the Hungerford-bridge are being taken down, measured, and arranged for re-erection at Clifton.

A large number of Messrs. Brown and Lennox's anchors, intended for the "Caledonia," and other iron-cased ships of war, were yesterday tested at Woolwich. The weight of each anchor averaged 5 tons 12 cwt., and the maximum test amounted to 72 tons.

At the meeting of the Mersey Docks and Harbour Board, on Thursday week, the special committee on plans for new works submitted for adoption a report (with plans) from the dock engineer, as to certain alterations proposed to be made in the intended scheme for the corn warehouses at the Prince's Basin, and the alterations at the said basin, involving an additional cost of about £36,500. Mr. Brocklebank said that the first feature was the enlargement of the entrance into the Prince's Dock Basin from 50 ft. to 65 ft. The next was the enlargement of the entrance into Waterloo Dock from 40 ft. to 45 ft. wide, with an alteration likewise in the position of the entrance, which he thought would be a very considerable advantage. The canal to the south of the Waterloo warehouses was enlarged from 100 ft. to 140 ft., giving sufficient space for two vessels to lie, one on each side, leaving a passage through the middle. These were the main features of the alteration in the Prince's Dock Basin, the addisional cost of which would be something like £18,000. The warehouses were proposed to be built fireproof, and to be supported on iron girders, by which means there would be a great saving of room upon the quay floor. The total cost of carrying out the plans would be £328,314. The engineer had now under his consideration some improved machinery, by which it was expected that the warehouses would be worked at a minimum of cost, seeing that it would both take the grain out of the vessels, and likewise distribute it through the various rooms without, he understood, much manual labour. The proceedings of the special committee were confirmed.

With reference to the utilization of town sewage (says a contemporary) a suggestion has been thrown out which appears worth attention. We are told that the fertilizing salts contained in the sewage are mixed with such an enormous quantity of water as to be comparatively valueless. But it is thought that the new chemical process of dialysis, discovered by the Master of the Mint, might be used on a great scale for the separation of the salts. The essential elements are there in the form of crystalloids and colloids, and it is for practical chemists to decide whether by the application of dialysis a question of so much importance can be settled.

A new Petroleum Trading Company is announced, with a capital of £100,000 in shares of £10 each. The object is to import petroleum from the natural wells in America in iron tank vessels specially constructed, which vessels will class A 1 for seventeen years. By this proceeding a large percentage will will be saved in freights. The demand for petroleum is yearly increasing for lighting purposes, and it is a cheap and efficient agent for the rapid generation of steam. The company possesses an able manager and a respectable direction; and it seems to promise considerable commercial success.

The Sewage Question.—A contemporary says that with reference to the utilization of towns' sewage (a much-debated question), a suggestion has been thrown out which appears worth attention. We are told that the fertilizing salts contained in the sewage are mixed with such an enormous quantity of water as to be comparatively valueless. But it is thought that the new chemical process of dialysis, discovered by the Master of the Mint, might be used on a great scale for the separation of the salts. The essential elements are there in the form of crystalloids and colloids, and it is for practical chemists to decide whether by the application of dialysis a question of so much importance can be settled.

Attachment to Carpenters' Jointers.—Mr. J. S. Dutton, of Jaffrey, U.S., suggests that carpenters should attach a guide to their long jointers, so that the frequent use of the try-square may be avoided. This he thinks will much facilitate operations, as the workman can rely upon the guide, where before he depended wholly upon his skill in securing a square face. "The guide should be made," says Mr. Dutton, "in the following manner:—Take a strip of hard wood, about two in. wide, 1 in. thick, and 3 in. longer than the jointer; joint this piece true, and fit one edge of it to the face of the jointer near the left hand side; it will cover about one-third of the face. This is the guide; in this position it must be fastened to the jointer, but so that it can be easily and quickly removed. One of the most simple modes of fastening is this: take two pieces of wire, each about 3 in. long and three-sixteenths of an inch in diameter, and fit these firmly into the edge of the strip, one near each end, leaving about one-half the length of the wires projecting outward. Make two corresponding holes in the face of the plane for these wire pins to enter; let the guide be well and tightly fitted at right angles with the face of the jointer, and project 1¼ in. beyond it at either end, to facilitate its removal. By this mode of fastening, the guide can be removed or replaced in a few seconds of time, and no injury result to the plane."

Parliament House, Edinburgh.—The *Scotsman* says that the suggestion recently made for the decoration of the walls of the Great Hall in the Parliament House, by hanging thereon the portraits, scattered through various parts of the building, of judges and other eminent personages, was on Monday carried into effect. The east wall is now tolerably well clothed by these portraits, and the improvement in the aspect of the hall is very marked. They have been hung with much care and taste under the superintendence of Mr. Charles Robertson, Treasurer to the Faculty, the larger and the smaller pictures being judiciously alternated and adapted to the nature of the spaces as these are broken up by doors, niches, and statues. There is room for many more, and no doubt time will add to the collection, for a painting thus conspicuously and appropriately placed is a scarcely less honourable or worthy memorial than a statue. The colour of the walls is rather too light to show the paintings to the best advantage, but this can be considered when they again require painting. The windows are the features most in need of alteration. If the great window, now so glaringly ugly, were refilled with really fine stained glass, and the side windows similarly treated, the hall would assume something like the appearance its noble proportions and grand roof well entitle it to do.

Filth and Fever.—In the last return of the Registrar-General, we find, among the notes of the district registrars, this social picture:—*Northallerton (Yorkshire).*—Births, 61; deaths, 39. Births and deaths are above their averages. Fever of different forms, and whooping-cough, are very prevalent in several parts of the district. The sanitary condition of this district is in anything but a satisfactory state; drainage is very bad, and heaps of putrifying filth are allowed to lie close to the dwellings of the poor. I particularly refer to the village of Brompton, where for some time synochus, typhoid fever, and typhus have been very prevalent. Here I find no drainage at all, no proper cesspools; yards unpaved, and dungheaps unremoved; the floors of the dwelling-houses beneath the level of surrounding land; and, what is still worse, the inhabitants appear to have a dread of ventilation. For years this village has been little else than a hotbed of fever, but this fact has not induced the authorities to adopt means of prevention. The mortality of children is excessive. Many infants are, when a few weeks old, left to the care of mere children, going for days without their natural food, but fed on scanty and improper diet. They die literally from neglect."

Meetings for the Week.

Tues.—*London Inst.*, "On Animal Mechanics," by Professor Marshall, at 3 p.m.
Inst. Civil Engineers, Discussion—"Drainage of Dundee and Sewerage of Newport Monmouthshire" at 8 p.m.
Wed.—*Soc. of Arts*, "On the Best Means for Promoting the Growth and Improving the Quality of Cotton in India." By A. Nesbitt Shaw, late Collector of Dharwar, and Commissioner of Revenue for the Northern Division of the Bombay Presidency, at 8 p.m.
Geological Soc., 1, "On the Middle and Upper Lias of the Dorsetshire Coast, by C. H. H. Day, Esq. Communicated by R. Etheridge, Esq. 2, "On the Correlation of the several divisions of the Inferior Oolite in the Middle and South of England," by Harvey B. Holl, M.D., at 8 p.m.
London Inst., "On the Zoology of Warm-blooded Vertebrata," by C. C. Blake, Esq., at 7 p.m.
Thur.—*Royal Inst.*, "On Chemical Affinity," by Dr. E. Frankland, F.R.S., at 3 p.m.
Antiquaries, at 8.30 p.m.
Linnean, at 8 p.m.
Chemical, at 8 p.m.
Royal Soc., at 8.30 p.m.
Fri.—*Architectural Assoc.*, "Ventilation," illustrated by models, by G. B. New, Esq.
London Inst., "On the Chemistry of the Non-Metallic Elements," by F. Field, Esq., at 7 p.m.
Geological Soc., Anniversary Meeting, at 1 p.m. Annual Dinner, at 6 p.m.
Royal Inst., "Recent Discoveries at Jerusalem," by Rev. G. Williams, at 8 p.m.
Sat.—*Royal Inst.*, "On the Science of Language," by Prof. Max Muller, at 3 p.m.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2017, 2037, 2058, 2079.
Boilers and Furnaces, 2342, 2060.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2014, 2020, 2045.
Ships and Boats, including their fittings, 2006, 2024.
Cultivation of the Soil, including agricultural implements and machines, 2028, 2030.
Food and Beverages, including apparatus for preparing food for men and animals, 2023.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2003, 2005, 2008, 2012, 2016, 2019, 2021, 2033.
Buildings and Building Materials, 2018, 2029, 2032.
Lighting, Heating, and Ventilating, 2001, 2025, 2026, 2027, 2034, 2052, 2054, 2056.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 2010, 2011, 2015, 2022, 2038, 2040, 2041, 2043, 2055, 2068.
Metals, including apparatus for their manufacture, 2004, 2009, 2013.
Chemistry and Photography, 2044, 2050, 2062.
Electrical Apparatus, 2070.
Warfare, 2002, 2007, 2063, 2064, 2067, 2072.
Letter-Press Printing—*none.*
Miscellaneous, 2031, 2035, 2036, 2039, 2046, 2047, 2048, 2049, 2051, 2054, 2057, 2059, 2061, 2066, 2069, 2071; 2073, 2074, 2075, 2076.

2001. W. Bliss. *Improvements in heating ores, and in generating steam, and also in apparatus employed therein.* (A communication.) Dated July 11, 1862.

Here a blast furnace is used which is closed at its lower end by a valve or slide, so that after the process of heating or calcining the quartz or ores, the contents of the furnace may be discharged through an opening in the body of the furnace, which is closed by a valve or slide during the heating or calcining process. At the lower part of the blast furnace there is a hollow space all round, into which air, and the gases obtained from decomposed steam, are forced during the process of heating or calcining the quartz or ores. A steam boiler is employed in connection with the blast furnace, by the fire used for heating which a retort is also heated, and it is found convenient to arrange this retort so that it may form the bridge across the end of the boiler furnace, but the retort may be otherwise arranged and heated. By means of a fan or other suitable blowing apparatus air is forced into the hollow space at the lower part of the furnace, and passes through several openings from such chamber into the lower part of the blast furnace, and it is preferred that the air thus forced into the furnace should be heated in its passage from the blowing apparatus to the furnace, by causing it to pass through a pipe or pipes or passages heated by the fire of the boiler furnace, but the heating of the air may be otherwise accomplished. In the retort charcoal is placed, and steam from the boiler is caused to pass through and amongst such charcoal, and from the retort the gases and any steam which may not be decomposed pass into the space at the lower part of the blast furnace, and thence through the passages into the blast furnace. In working with this arrangement of apparatus a quantity of fuel is placed at the bottom of the blast furnace, and also the quartz or other ores requiring a like process; air and gases are forced into the blast furnace, by which a very high degree of heat is obtained. After a time it is preferred to stop the introduction of the air blast, and to continue the application of the gases till the process is complete. The air and gas pipes are protected by fireclay or bricks when using the apparatus for generating steam to be applied to work steam engines; and where no heating or calcining furnace is used, the gases obtained from the same are used in the steam boiler furnace. *Patent completed.*

2002. C. E. Green and J. Green. *Improvements in breech-loading firearms.* Dated July 12, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2003. J. P. Lees and J. Beard. *Certain improvements in carding engines.* Dated July 12, 1862.

This consists in an improved combination and arrangement of parts for regulating the set of the top flats of carding engines. Each end of each top flat is supported on a piece of metal or other suitable material, which is hinged to and capable of swivelling upon the rounded end of a screw, technically called the set of the card, being adjusted by two set screws passing through the swivel piece. The distance between the cards on the top flat and the cards on the main cylinder is regulated by the screw above referred to passing through the bend of the side frame, and a screw nut, and by a set screw entering into the end of the other screw. *Patent abandoned.*

2004. J. Abraham. *Improvements in presses for raising or shaping metals.* Dated July 12, 1862.

This has reference to the feeding into the press of the blanks to be raised, and the removal of the raised articles from the lower die. The inventor describes his invention in connection with a lever press worked by a lever handle. The blanks to be raised are fed to the press from a table a little higher than the level of the lower tool or die, and are pushed by hand from the said table to an inclined plane, down which they slide to the lower tool or die. The article raised is pushed from the lower die in the following way:—A nearly horizontal connecting rod, situate at about the level of the lower die, is jointed at one end to the vertical connecting rod which joins the treadle to the lever of the press, and at its other end to a lever fixed to the lower die. When the foot is lifted from the treadle, the horizontal connecting rod is restored to the horizontal position from which it had been displaced while the treadle was pressed upon by the foot, and, giving motion to the small lever on the lower die, pushes the raised article from the said lower die. *Patent abandoned.*

2005. J. Hunt. *Improvements in process of sizing and drying yarns or threads, and in the apparatus employed in such process.* Dated July 12, 1862.

This applies to what are known as tape-sizeing and slashing machines, and consists, principally, in opening, dividing, or separating the yarn whilst in a wet state, immediately after it leaves the finishing size rollers, and before it goes on, round, or over the drying cylinder or cylinders of the machine into two sheets or layers, or into as many sheets or layers as there may be back beams used in the machine. All these sheets or layers then proceed over the drying cylinder or cylinders of the machine. *Patent abandoned.*

2006. M. A. F. Mennons. *Certain improvements in vessels mounted as floating batteries.* (A communication.) Dated July 12, 1862.

The patentee claims the arrangement of fittings by means of which projectiles may be directed from below the water line against a corresponding point of the enemy's ship. *Patent completed.*

2007. T. Hill. *Improvements in the arrangements employed for the protection of markers at rifle butts, and in the means employed in indicating the score and position of the shot, and wiping out the shot mark.* Dated July 12, 1862.

The object here is for the better protection of the markers when engaged at rifle butts or targets, together with improved means of indicating the score and position of the shot upon the targets whilst the marker is in the act of wiping out the same. For this purpose, in order to protect the marker, a pit is sunk in front of the target, part of which is protected by a strong covering of iron plates or other materials. The covering of the pit nearest the target is to be, by preference, inclined, and has a sheet of thick plate glass inserted therein, in orded that the marker may see when the target is struck. On one side of the pit an opening is left, from which the marker can reach the face of the target, without any exposure of himself, in order to wipe out each shot mark in succession, and one part of the invention consists in using a series of brushes or instruments for this purpose, which in the act of wiping out, indicate to those at a distance the character of the shot mark, together with its exact position upon the target. *Patent completed.*

2008. E. T. Hughes. *An improved system of winding or rolling silk threads on moulds or bobbins, and placing them in suitable boxes.* (A communication.) Dated July 12, 1862.

Here the inventor winds, rolls, or plaits the thread in pellets, cylinders, or moulds, and also bobbins of various sizes, according to the purpose for which the thread is required. *Patent abandoned.*

2009. J. H. Johnson. *Improvements in machinery or apparatus for washing ores and minerals.* (A communication.) Dated July 12, 1862.

This invention consists in the employment of a long vessel filled with water, and fitted near the upper part with a trough slightly inclined towards one end; this trough receives the minerals to be washed. It has a vibratory motion communicated to it by means of an eccentric fitted on a shaft for that purpose. The trough likewise receives a rocking motion in a lateral direction. These combined motions cause the minerals to be separated according to their quality and degrees of fineness. The minerals are supplied to the trough by means of a hopper, into which a jet of water from a pipe is forced in fine streams. The bottom of the main vessel is furnished with divisions or apertures from which the separated and cleansed ore is removed. *Patent completed.*

2010. W. E. Gedge. *Improvements in the manufacture of hats.* (A communication.) Dated July 12, 1862.

Here the hat is made from felt prepared in the usual way, but of much lighter weight than ordinary, and is blocked to form, as is usually practised, except that care is taken to burn off with the blocking-iron all the hairs, and leave a polished surface. This form is then covered with three successive coats of gummy solution, each having been allowed to dry before the next is laid on; then a coating of varnish is applied all over, and the cloth or other material forming the outer covering placed or drawn thereon. *Patent abandoned.*

2011. P. Plassau. *An orthopædic apparatus to straighten again the stature.* Dated July 12, 1862.

This apparatus is, under one modification, composed of strong woven fabric, which is placed on the pelvis above the trochanters. This belt is made in two pieces, more or less closely brought together at the back by a couple of straps or a lace. The two anterior or fore parts of each of these pieces have eyelet holes or buckles, and thick pads are so placed inside the belt as to press on the inguinal region within the ilium, where the inguinal bandage is made to pass in cases of the hernia, so called. By this means the belt is prevented from turning and unpleasantly pressing or squeezing the hypogastric region. *Patent abandoned.*

2012. D. Bateman. *Improvements in the manufacture of "card cloth," used for carding wool and other fibrous substances.* Dated July 12, 1862.

Here the inventor makes card cloth of an admixture of linen and wool, the warp being linen and the weft of wool, or of woollen felt or woollen cloth, or a mixture of cotton, linen, or woollen cloth, and he treats the front surface of the card cloth with a composition which is impervious to the action or influence of oils or grease. He uses a mixture of one gallon of boiled linseed oil, four to six pounds of rice flour, half a pound of common glue, marine or other waterproof glue, and two pounds of gum, with which he treats or coats the front or both surfaces of the card cloth, and fixes thereto a covering of waterproof enamelled cloth, with the surface prepared with a mixture of one gallon of boiled linseed oil and one pound of lamp black for the first coats, and with boiled oil and yellow ochre, or other metallic or mineral powder for the finishing coats, and to give it the colour required so as to form a perfectly pliable and uniform surface. *Patent completed.*

2013. H. Barber and H. De Garrs. *Improvements in rolling iron, steel, and other metals, for cutting tools and other purposes.* Dated July 12, 1832.

This consists in rolling iron, steel, and other metals for manufacturing cutlery, tools, &c., so that the material when rolled shall vary in thickness across its width, so as to correspond with the varying thickness of the article for which it is intended. *Patent completed.*

2014. The Hon. W. E. Cochrane. *Improvements in railway fastenings.* Dated July 13, 1852.

Here, when using plates with studs or projections thereon, corresponding to the holes made in the ends of rails such as are usually formed for receiving screw bolts of fish plates, the plates are each so made that they have as many studs or projections as there are holes made in the ends of two rails, which is not new; but in place of making the outer surface of such a plate as heretofore, it is formed with a projecting incline on that part which comes within and below the top of the outer jaw of a joint chair, in which the ends of the two rails are to be fixed and retained by the plate. In addition to such incline there are two other projections formed near the upper part of the plate, so as to come, when the plate is in its place in the chair, on either side of the outer jaw of the chair and near its top. These projections form stops, which prevent the plate and also the rails striking longitudinally within the chair. Between these two projections or stops there are formed projecting ribs, which do not extend so far out from the outer surface of the plate as the stops, and it is between these ribs that the wedge is driven. The plate, when it has been introduced between the ends of the two rails and the jaw of the joint chair, is fixed therein by means of an iron wedge, which is driven between the jaw of the chair and the projecting incline on the outer surface of the plate. The inner surface of the wedge and the projecting ribs are formed with grooves or notches, so that when the wedge is driven tightly in its place it may be prevented becoming loose by driving a nail down through one of the notches or grooves in the projecting rib of the plate, and in the inner surface of the wedge. *Patent completed.*

2015. E. Taylor. *Improvements in the manufacture of buttons.* Dated July 14, 1862.

This consists in a mode of fastening on buttons without sewing. The shank of the button is separate from the face, and is passed through a hole in the centre of the button, it having a head or other projection to prevent its passing through entirely. This shank is made of hollow tubing, or solid metal, or other material, such shank passing through the stuff to which the button is to be attached. The shank has a small metal or other plate put over it, which is to be pressed, rivetted, or screwed, so as to prevent its drawing through, also a raised shoulder or collar to attach or hold a second plate to press the material holding the button. *Patent abandoned.*

2016. G. Lowry. *Improvements in machinery for carding and cleansing cotton and other fibrous materials.* Dated July 14, 1862.

The first part of this consists in adapting a brush with an intermittent or continuous rotary motion, or with a reciprocating action, or a to and fro movement, during the working of the main cylinder of carding engines, together or in conjunction with a self-acting comb, which is cleared of the motes and other impurities by a perforated or recessed plate, or plain plate, or straight edge, and deposits the same into a trough or other suitable receptacle, whence they are removed as described in the specification of letters patent granted to the present patentee, bearing date Nov. 25, 1861 (No. 2954). The second part consists in making the main cylinder of carding engines with a flanged periphery projecting above the points of the wire clothing, to prevent the fibrous material escaping over the ends of the main cylinder. The third part relates to tow and waste shaking machines, and consists in placing the finger shafts at an incline, and at opposite sides of the machine, to which is applied a self-acting feed eloth or creeper, and a fan to carry off the dust. By this arrangement the material is continuously supplied and discharged, whereas in machines of the ordinary construction, the material is supplied in quantities, and removed when operated on by hand. *Patent completed.*

2017. W. E. Gedge. *An improved portable or stationery steam-lift and force-pump.* (A communication.) Dated July 14, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2018. A. A. Gannal. *Certain improvements in the manufacture of bituminous cement.* Dated July 14, 1862.

This consists in combining sandy earth, or, by preference, river sand, with a quantity of bituminous substance, equal in volume to the sum of the spaces between grains of well pounded sand. *Patent abandoned.*

2019. C. Crossley and J. W. Crossley. *Improvements in means or apparatus employed in washing and finishing textile fabrics.* Dated July 14, 1862.

This invention consists in passing fabrics through a "heck" and over rollers at an elevation, in order to undo the twists and separate the draughts. A cutter is attached to a washing machine called a "dolly," which enables the patentees to separate all the draughts of fabrics at one time. The second part of the invention relates to the calendering and watering of fabrics, by using three rollers, in such manner that the goods may be placed on and around the centre one, pressure being applied by means of levers or screws. The reversing motion of the driving apparatus is so arranged that the rollers can be driven in opposite directions, to produce a better finish to the goods than heretofore. The rollers may be heated or not, and paper may be used to assist in giving a gloss to the fabric. *Patent completed.*

2020. S. Partridge. *Improvements in railway signals.* Dated July 14, 1862.

This invention consists in arrangements of railway signals, whereby the driver and passengers of a train arriving at a signal may be informed of the time which has elapsed since a train or engine last passed the signal. The mechanical contrivances employed are a weight and pendulum and certain toothed wheels, whereby discs are removed from dials, which give the desired information. *Patent completed.*

2021. P. Sanderson and R. Sanderson. *Improvements in the manufacture of woven fabrics, and in the machinery or apparatus employed therein.* Dated July 14, 1862.

This relates to the manufacture of a particular kind of cloth suitable for wearing apparel. This cloth is woven so that, at regular intervals, a loop is formed on the surface of the cloth, which imparts a peculiar knotted appearance to the finished goods. These loops are formed at predetermined distances asunder in the width of the fabric, and at a regular distance longitudinally, by weaving a given number of shots of weft between each transverse row of loops. *Patent abandoned.*

2022. W. G. May. *Improvements in apparatus for extending tables.* Dated July 14, 1862.

Under one modification, this extending apparatus consists of a series of adjustable bars or laths, arranged and jointed together to form what is known as the lazy tongs movement, and admit of the table being extended or contracted, at pleasure, within the limits of the lever arrangement. To one end of the frame of the table is fixed a bracket-piece, to which are jointed two bars, or laths, that form the first of the series. These bars extend outwards to the width of the table. To the free extremities of the primary bars, or laths, are jointed two other bars, which are jointed at the centre, where they overlap one another, and are sufficiently long to extend quite across the width of the table in an angular direction. The free ends of these secondary bars are jointed in like manner to third pair, and so on until a sufficient number of pairs of bars, or laths, are connected together to obtain the required amount of extension. The series of bars, or laths, is completed by a short pair, similar to the first, which are jointed, in like manner, to a bracket-piece fixed to the framing at the opposite end of the table. A hand-lever is attached to one end of the bars, or laths, and is arranged so that it may be turned outwards, so as to project beyond the side of the table. By turning this lever in one direction, the system of bars, or laths, are caused to extend, and so carry the telescope framing of the table out to the full extent, or any desired portion thereof. *Patent abandoned.*

2023. P. A. S. Canonicat. *Improvements in filtering water, and in apparatus employed therein.* Dated July 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2024. G. Fawcus. *Improvements in building boats.* Dated July 14, 1862.

The object of this invention is the constructing of boats in such manner that any number of boats of the same size will fit one within the other. The patentee dispenses, if desired, with internal projections, and makes the thwarts to fold, and supports them by an iron upright when shipped. He employs flat, half round, or angle-iron or iron plates, to impart the necessary strength. *Patent completed.*

2025. F. M. Parkes. *Improvements in the manufacture of gas for lighting and heating, and in apparatus employed in the said manufacture.* Dated July 14, 1862.

This consists in the manufacture of gas by the combination of the gas obtained from petroleum or rock oil (which is also known by various other means) with the gas commonly termed hydro-carbon gas, or water gas. And further, in the peculiar apparatus or retort represented in the drawings. *Patent completed.*

2026. O. P. Drake. *A new and useful or improved apparatus for vaporizing and aerating liqiud hydro-carbon to be burned for illumination, or for other purposes.* Dated July 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2027. R. Ridley and J. Grafton. *Improvements in machinery and apparatus for ventilating mines and other places.* Dated July 14, 1862.

For the purposes of this invention, at the top of the upcast shaft of a mine, a hollow rotating apparatus is placed, which has an opening through its under surface, or through that surface which is next the mine, such opening being, by preference, of a diameter (as near as may be) corresponding with the diameter of the upper end of the upcast shaft. This apparatus consists of the under cover or end with the opening into it, and an upper cover or closed end to which an axis or shaft is fixed in its centre, which axis or shaft passes through the closed end, where it is put in motion by any suitable power; the lower end of the axis steps into and is supported by a suitable bearing, carried by a bearer or frame fixed across the upcast shaft. The upper end of the axis or shaft also turns in a suitable bearing outside of the apparatus, carried by a suitable beam or framing external of the apparatus, and fixed to the band above the upcast shaft. The periphery of the apparatus is not cylindrical, but is formed with openings (by preference four) in planes radiating from the centre of the apparatus; the circumference of the apparatus is closed, except at these openings, by four curved plates (if there be four openings or outlets), each of which plates springs from the inner end of one opening, and passes to the outer end of the next opening. Provision is made in the under surface of the apparatus, so that air may not pass from the outer atmosphere into the apparatus. The apparatus when in use is caused to rotate with considerable velocity, in such direction that the air, rising up the upcast shaft, is drawn into the interior of the apparatus, and flows out of the several openings. *Patent completed.*

2028. A. Lislik. *Improvements in apparatus for applying steam or other motive power to cultivate the soil and to actuate wheeled carriages.* Dated July 15, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2029. A. Couvreaux. *A centrifugal apparatus for breaking stones.* Dated July 15, 1862.

In carrying out this invention the patentee employs a large wheel, on which are rivetted plates, so as to form a series of paddles, and these are rivetted to angle iron, so that the whole is firmly fastened and made sufficiently strong. It works in a wooden frame, which also carries the bearings of the shaft or axle. Over this wheel, and inside the frame, he places a number of plates of strong iron, at such an angle as to enhance their strength, while at the same time they are so fixed to break stones or other earthy matter that may be thrown against them with great force at which the wheel throws them, and after being dashed as it were off at a tangent from the different teeth or paddles on the rim, they finally arrive on a shoot down which they slide into a heap and are ready for use. At the opposite side of the frame to this shoot there is a platform with an inclined board, down which the stones or other matters descend on the teeth or paddles of the wheel, which is driven by a strap from a steam-engine. *Patent completed.*

2030. J. Green. *Improvements in the method and means of producing signals, and in the application of the same, particularly to steam ploughs or cultivators.* Dated July 15, 1862.

This invention consists in employing and so arranging a wire or cord, composed of hemp or other material, that the ploughman and anchormdn are thereby enabled at any time to make signals to the man at the engine or windlass. In order to effect this, the patentee attaches one end of the wire to a drum or pulley, which is secured to the engine or windlass in a suitable manner. The other end of the wire is fastened to the anchor, or other suitable frame, fixed at another side of the field intended to be operated upon, consequently the wire is then extended from one side of the field to another. The plough or other implement connected with the wire by means of a rectangular shaped frame, having two loop holes or eyes, through which the wire is run; this frame is attached to the plough, and as that moves along, the loop holes or eyes slide along the wire, that being extended parallel to the track of the the plough. The wire is kept tight by means of a smaller pulley or drum acted on by a cord or weight, and as this pulley is fixed upon the axis of the drum before mentioned and is connected with the latter by means of a ratchet wheel and spring catch, it constantly tends to wind up or coil the wire round the larger drum. When the wire is pulled, a series of studs or pegs on one side of the drum to which it is attached give motion to a lever fixed on the frame, which communicates with a bell or whistle, or other signal. When the wire is let go the smaller pulley, by means of the cord and weight, brings back the drum to its former position, and thereby tightens the wire again. *Patent completed.*

2031. A. Couvreaux. *A centrifugal apparatus for throwing stones, earths, and other materials.* Dated July 15, 1862.

In carrying out this invention the patentee makes use of a large wheel, which revolves at a very high speed, and on which is placed a series of paddles or buckets; the stones are conveyed into the inside of the frame by means of a shoot, and are taken up by these paddles or buckets and thrown off at a tangent through another shoot, which can be elevated or lowered according to the distance they are required to be thrown. The whole is mounted on a wooden frame, and the wheel is driven by means of a pulley and strap from an engine or any other convenient motive power. *Patent completed.*

2032. E. Draper and E. Thomas. *A new or improved method of strengthening wooden shutters and doors.* Dated July 15, 1862.

This invention consists in the application of hardened and tempered steel or iron plates to doors and shutters as a means of defence against burglars. Also in hardening and tempering the said plates by pickling them in sulphate of potash, arsenic, rock salt, and water. *Patent abandoned.*

2033. W. Dickens and J. Hewitt. *Improvements in self-acting and hand mules employed in spinning cotton and other fibrous materials.* Dated July 15, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2034. C. E. Crawley and F. Foster. *Improvements in safety or miner's lamps.* Dated July 15, 1862.

This invention is applicable more especially to safety or miner's lamps in which a circular wick and burner are employed, and consists in combining a locking bolt with the apparatus which raises and lowers the wick, to increase, diminish, or extinguish the light. This bolt serves to lock the wire gauze in its place, and it is actuated by the same button which serves to regulate the wick. The same motion which lowers the wick withdraws the bolt, and the parts are so adjusted that the wick must be depressed sufficiently to extinguish flame before the wire gauze is set free to be removed. *Patent completed.*

2035. T. G. Ghislin. *Improvements in the treatment or preparation of British and foreign algæ, and the application of the same to various branches of the arts and manufactures.* Dated July 15, 1862.

This invention consisis in treating or preparing British and foreign seaweeds of the order *algæ*, so that they may be used for various useful purposes in the arts and manufactures. In carrying out this invention, the seaweed should be first steeped in dilute sulphuric acid for about three hours, and then well dried, so as to become hard, after which it is to be ground up or reduced to an almost impalpable powder. The dry powder is then to be mixed, in any convenient proportions, with the ingredients hereinafter named. The patentee first prepares a strong glutinous solution, composed of common glue dissolved in water, to which must be added a solution of india rubber, gutta percha, or other analogous substances. In practice, he finds the following proportions are convenient, viz.:—10 per cent. of glue, dissolved in water, 5 per cent. of gutta percha, and 2½ per cent. of india rubber, dissolved in naphtha, or other suitable solvent of these gums. To these he adds 10 per cent. of coal tar. These substances are all well mixed and boiled together. He then adds thereto, in a dry state, 5 per cent. of sulphur, 5 per cent. of rosin, and 2½ per cent. of alum, and, say, 60 per cent. of the pulverized seaweed. He carefully and intimately mixes the pulverized ingredients in the boiling compound, and, when the ingredients have been well incorporated, the mass must be submitted to heat in a suitable oven, taking care that the mixture be not heated above 300 deg. Fahr. The mass will then be brought into a plastic state, and may be moulded or embossed in the same way that gutta percha is now done, or rolled, pressed, stamped, or otherwise formed into any desired shape, and thereby adapted, when it becomes hard, for various useful or ornamental purposes. *Patent completed.*

2036. B. Johnson and E. H. Taylor. *Improvements in rope wheels, cages, and tanks used for mines, collieries, and other similar purposes.* Dated July 16, 1862.

The object of this invention is to afford the means of a ready adjustment of the length of the winding rope or chain between the rope wheel and the cage or article to which it is attached. On the shaft of the rope wheel, the inventor fixes a boss in two parts, each having a flange on the outside, so as to form between them a circular groove, into which is fitted the rope wheel in such manner that it may be turned upon the boss or upon the shaft when required, and afterwards bolted to the side flanges by bolts. In the side flanges, he drills, in a circle of a given diameter, a number of holes, and in the solid part of the rope wheel around the boss, he drills in a circle of the same diameter one, two, three, or more holes more than there are in the side flanges, so that the bolts employed for holding the wheel and boss together can be passed into different holes, and thereby obtains a very delicate adjustment of the length of the rope. Thus, when there is one hole more in the rope wheel than in the flanges, if two bolts have been passed through two sets of holes opposite each other, and then withdrawn so that the rope wheel can be turned to allow them to be passed through the next set of holes, the winding rope will be shortened a distance proportionate to a fractional part only of the circumferential distance between the holes, and if the rope wheel be turned to the next following set of holes, another fractional part will be added, and so on, the different numbers of the holes producing an effect similar to the use of the vernier in philosophical instruments. When the boss consists of one part only, the rope wheel is to be formed of two parts, in order to place it between the flanges; or the plan may be varied by having the wheel of one piece and one of the flanges moveable. *Patent abandoned.*

2037. G. T. Selby. *Improvements in apparatus for superheating in tubes and tubular articles, and in machinery for the manufacture thereof.* Dated July 16, 1862.

In carrying out this invention the patentee constructs superheaters of one or many tubes of a worm or spiral form, through which the steam or gas to be superheated passes; heat from the furnace is outside round about them. They may be placed in the funnel stack, fire or smoke-box of a steam boiler, or in any convenient part of a furnace, or in a furnace made for their reception. The tubes being spiral, expansion and contraction in the length of the tube are accommodated without affecting the joint or connection to the part where the tube is fixed. When many (or a series of) spiral tubes are required, he makes the connections between them of tubes formed for the purpose, with thicknesses of metal at that part where the joint is made. This thickness is of greater substance than the other parts, so that the joints may be effectually made, either by the ends of the spiral tubes being screwed in or otherwise. A similar extra thickness may be formed on the opposite part, in order that the whole may expand and contract more uniformly. This kind of tube is particularly useful in the construction of surface condensers, it being only necessary to provide a suitable thickness of metal at those parts where the joints and connections are made, the other parts of the tube being thinner. These thick-sided tubes or tubular articles are useful for many other purposes, particularly for bridge and roof girders, and for pillars. The machinery by which these tubes are made is somewhat similar to that which is used for making and welding iron tubes, but the dies used at the draw-bench for bringing the edges of the piece of metal together, preparatory to welding them, are shaped so as to allow the projections or thicker part of the metal strip or sheet to pass through when the desired form has been given to the thickness of the piece of metal, in the usual way, by grooves formed in the rolls of the rolling mill. When, however, the extra thickness is given, as hereinafter described, the tube or tubular article is prepared and welded in the usual way. When the tube is thus prepared it is placed in a furnace and brought to a welding heat, and then passed through rolls to weld the edges together. The inside should be supported by a mandril, such as is used for welding iron tubes, and the rolls may be a set of 2, 3, or 4, similarly constructed to those now used for welding iron tubes, with this difference, that on one roll, or on all the rolls, or on opposite rolls, a groove is made to correspond with the shape and thickness desired to be given to the outside of the tube or tubular article, and the mandril must be shaped to give the desired internal form and thickness to the tube or tubular article. But the patentee prefers to give the desired extra thickness by partially fixing, externally or internally, or both, either by welding at the ends, or by rivetting, a flat or suitably shaped piece of iron on an ordinary tube, and then passing the whole at a welding heat through grooved rolls, as above described, so as to weld the whole length of the piece or pieces of metal on to the tube. *Patent completed.*

2038. L. R. Bodmer. *Improvements in apparatus for winding up watches and other time-keepers.* (A communication.) Dated July 16, 1862.

These improvements relate to certain apparatus or mechanism for winding up the main-springs of watches and other time-keepers without the use of a key, by means of a chain, one end of which passes through the handle or knob of the watch, where it is secured to a steel pin with head, which fits into a socket of the watch knob or handle. The chain is wound round a grooved pulley, which latter fits upon a bush upon the square arbor of the main-spring barrel. Upon this bush is fixed a ratchet wheel into which takes a pall moving round a stud in the chain pulley. The chain pulley is provided with teeth on its circumference which gear into the teeth of a wheel turning loosely round a bush of a square stud fixed to the watch plate. The body of this wheel forms, or has attached to it, the barrel of a second spring, one end of which is fixed to the bush, and the other to the circumference of the barrel, in the usual manner. On taking hold of and drawing out the pin head of the chain which rests upon or fits into the watch knob, the pall on the pulley taking into the ratchet wheel carries round with it the main-spring barrel, thereby winding up the main-spring, and at the same time the second spring above referred to is wound up. When the hold on the chain is relaxed, this second spring will turn its own barrel and wheel, and therewith also the chain pulley, in the opposite direction, and thus again wind up the chain round its pulley, the catch gliding, during the latter operation, over the teeth of the ratchet wheel. A tappet actuated by a spring, presses the chain into its groove, and ensures its being wound closely coil upon coil on the chain end being released. *Patent abandoned.*

2039. W. Henson and W. W. Clay. *Improvements in knitting machinery, and in apparatus connected therewith.* Dated July 16, 1862.

These improvements have for their object the manufacture of looped or knitted fabrics in circular and straight frames. By means of these improvements the patentees produce a superior article with an increase in quantity to what has been heretofore produced in the same period of time. These improvements relating to the circular frame, and which are also applicable to the straight frame, are as follow:—Each head consists of an inner head, provided with a pipe at the lower end, which revolves in a boss cast on the frame of the machine, and bored truly out to receive the said pipe of the inner head. The lower end of the pipe projects through the boss, and is provided with a spur or bevel wheel gearing into a similar wheel on a shaft driven by hand or power. The upper end of the inner head is turned down and fitted with a ring, which projects somewhat beyond the head at the outside thereof. This ring is provided with the number of saw-gates required; in each saw-gate the upper end of a needle is free to slide up and down; the lower ends or stems of the needles are secured in the needle bits, which slide in saw-gates in another ring on the outside of the inner head, this ring lying below the ring first above mentioned. The ring first mentioned is secured to the inner head. The needle bits have a projection on the lower end on the outside; ther these projections take into a groove cut on the inner side of a ring; or a groove may be formed by (that is between) two rings secured to another ring lying outside them, so that by the revolution of the inner head the needle bits and needles will be alternately raised and depressed, the needles thus performing the well-known action, though actuated by the novel arrangement described. Instead of employing looped wheels to gain the loop, and a presser wheel to press the beards of the needles, the patentees use the following apparatus:—Outside the ring in which the needle bits slide is a series of projections in advance of the needle bits. This ring has as many saw-gates on it as there are needles in the head, and in each saw-gate is a lever which is somewhat bent at the upper end; the lower end is hinged or otherwise attached to the ring. Or the levers may be soldered in the saw-gates of the ring, and act as springs, the upper bent ends in either case being exactly opposite the beards of the needles, so that, as they rise up above the springs or levers, they are fed with a thread of silk, cotton, or other material, and as they descend, the bent ends of the springs or levers are pressed upon the beards, and hold them down close to the stems, to allow the previously formed loops to pass over the beards. The pressure on the springs or levers is obtained by the revolution of wheels or discs of metal supported by brackets on the outside of the frame. *Patent completed.*

2040. A. V. Newton. *An improvement in sewing machines.* (A communication.) Dated July 16, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2041. C. Sanderson. *Improvements in the manufacture of crinoline or crinoline steel.* Dated July 16, 1862.

The object of the present invention is to coat or cover the crinoline steel with a coating or covering of pulp produced from cotton, flax, or any vegetable or animal material which is capable of being converted into a pulpy state, and then solidified on the steel. *Patent abandoned.*

2042. R. Dunn. *Improvements in furnaces.* Dated July 16, 1862.

According to one part of this invention, it is proposed to make the fire bars tubular, and to construct them in two or more lengths, the tube of any one length being fitted so as to correspond with the tube of the contiguous length or lengths, with the view of forming a continuous passage for air from the front of the furnace to the bridge. The length next the bridge fits into a metal frame or chamber upon which the bridge when used is placed. Through, and at the back of this frame or chamber are (one or more) orifices, by which the air passing through the tubular bars makes its egress, and then mingles with the gases evolved from the fuel, whereby the combustion of such gases is caused. Another part of the invention consists in forming openings on the under sides of the tubular fire-bars, so as to admit air thereunto, which air will then pass along the tube even when the front portion of the bars has become stopped up. *Patent completed.*

2043. M. Kurts. *A new or improved material to be used in the manufacture of handles for umbrellas, parasols, and walking sticks.* Dated July 17, 1862.

The patentee claims the application of Jambees cane to the manufacture of handles for umbrellas, parasols, and walking sticks. *Patent completed.*

2044. J. Dickson. *Improvements in the manufacture of caustic soda and carbonate of soda.* Dated July 17, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2045. H. Appleby. *Improvement in armour plates for ships of war floating and land batteries, and other like purposes.* Dated July 17, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

2046. G. Harkness. *An improved safety handle for winches and cranes, and other like machines.* Dated July 17, 1862.

The object of this invention is to prevent the handle of winches, cranes, and other like machines, from revolving with the driving shaft during the operation of "lowering," "paying out," or unwinding, as accidents frequently happen to persons employing such machines, by the great speed at which the said handles usually rotate. The lever and hand bars of the handle are of any suitable or usual form, but the aperture or eye near the end of the former is made of an oval or other suitable form, having length, and the driving shaft on which it is to be placed is circular. Forming part of, or attached to the handle at its extreme end, and just beyond the aperture or eye above mentioned, is a "catch piece." The drawing pinion or wheel, or other wheel fastened to the driving shaft (or, if there be no convenient pinion or wheel, then a disc fastened to the driving shaft), has two or more studs or pins cast or otherwise fastened thereon. When it is desired to raise a weight, say, by any machine of the class above mentioned, then the oval or other formed aperture or eye allows the handle to be moved sufficiently to bring the so called "catch piece" to bear on the sides of the said studs or pins, and thus make a purchase for the handle, which has power applied in the usual way. But when it is desirable to lower the weight, then the handle is moved in the contrary direction—that is, until that end of the aperture or eye nearest the end of the lever bar is close up to or on the driving shaft—and the catch piece no longer bears on the studs or pins, but it rests near the shaft within the circle described by the said studs or pins as they rotate with the shaft; the lever bar is made with a shoulder or bend sufficiently large to allow the said studs or pins to pass without coming in contact with it. *Patent abandoned.*

2047. J. Schloss. *Improvements in pouches.* Dated July 17, 1862.

This invention relates to india-rubber pouches, and consists, firstly, in forming them with a flap cemented at the edges to the sides of the pouch, and loose or unattached all along the front end of the flap. The pouch itself is narrowed towards the mouth, and, the flap being cemented to the edges, causes a spring-like action to keep the flap closed. The invention consists, secondly, in forming pouches with a single piece or flap in the form of a flat ring, cemented all round or at intervals to the edges of the pouch. To get at the contents of the pouch, the edges of the ring are turned back all round, when the mouth of the pouch is disclosed and opened. By turning the edges of the ring in the reverse direction, the mouth of the pouch is covered, and the contents prevented from getting out. *Patent abandoned.*

2048. T. B. Daft. *Improvements in the manufacture of mats and other surfaces where vulcanized india-rubber is employed.* Dated July 17, 1862.

In making mats or other surfaces having strips or narrow fillets of vulcanized india rubber, the strips are used, say, about three-quarters of an inch wide by a quarter of an inch thick, and laths of wood or other hard material, say about three-quarters of an inch wide by a quarter of an inch thick; these are nailed down upon a board, the wood and rubber strips alternately, the wood flatwise and the rubber edgewise, thus forming projecting surfaces of india-rubber or other elastic ridges of about half an inch above the strips of wood or other material. If wavy or undulating lines are desired instead of straight ones, the sides of the fillets or strips of wood are formed wavy, and the rubber strips are made to follow them. In making thick mats, which are sometimes preferred, having elastic ridges an inch or more in depth above the hard surface, strips of wood or other hard material, say one inch and a quarter by three-quarters of an inch, are prepared of a certain length, say three feet, and rubber strips are prepared the same length, and of a section, say about two and a quarter inches by a quarter of an inch; these strips of wood and rubber are to have holes of about half an inch diameter made in them about six inches apart, and in such a way as to allow rods of iron screwed at both ends being put through them, first a strip of wood and then a strip of rubber, finishing with a strip of wood, and having enough of each to make a width of about two feet; the holes are to be formed in the wood and the rubber respectively, so that the surfaces shall be even on the under side, but on the top side the rubber shall stand up edgewise above the wood about an inch; nuts are screwed on to the iron rods, and all made firm and tight. This arrangement makes a very effective mat or shoe cleaner, and when a strip is worn down or destroyed, it can with facility be replaced. *Patent completed.*

2049. T. B. Daft. *Improvements in the manufacture of vulcanized india rubber thread.* Dated July 17, 1862.

The india rubber used for this purpose is cleaned, ground, and mixed with a proper quantity of sulphur, to cure or vulcanize the thread made from the mixture when it has been subjected to the requisite process of heat. The sheet produced from this compound of india rubber and sulphur may be spread in the usual way in which sheets are made for the purpose of being vulcanized, and afterwards cut into thread, and which process of spreading is well known. Or it may be produced by simply rolling out the compound after it has been well blended and mixed, or otherwise suitably prepaed, which processes are also well known. A sheet of sulphurized india rubber, either spread or rolled to about the thickness of the diameter of the thread required to be made, is cut up into strips of the full length of the sheets, and of a suitable width for the apparatus. If the sheets be of great length, the thread will be in proportion; if short, the thread will be short also; but if very long lengths of thread are required, and it be inconvenient to spread sheets accordingly, or to roll them out of the requisite length desired, then one sheet may, in the sulphurized state, be readily joined endwise to another; and in this way, or by similarly joining the strips of a few inches wide endwise, the means of obtaining thread of any desired length will be obvious. India rubber compound, fresh from the spreading or rolling, is liable to shrink, particularly when the compound of india rubber and sulphur is of the best and purest materials, such as should always be used in the manufacture of thread; and it is preferred that it should be submitted to a setting, or seasoning, process. Time will effect this at ordinary atmospheric temperatures, but it may readily be done by submitting it to the effect of boiling water for a short period, according to the bulk of materials being operated on; or if water under pressure, or steam at 250 deg., or thereabouts, be employed to set it, a still shorter time serves to season, set, or shrink it. *Patent completed.*

2050. W. Gossage. *Improvements in the decomposition of chloride of sodium and chloride of potassium, for the production of compounds of soda and potassa.* Dated July 18, 1862.

The patentee claims,—1. The decomposition of chloride of sodium and chloride of potassium for the production of certain compounds of soda or of potassa, by causing such chlorides, or one of them, when in the state of vapour mixed with the vapour of water, and mixed with gaseous products of the combustion of fuel, to be brought into contact, at an intense heat with lumps or pieces of certain solid substances, in such manner as to provide for such mixture of vapours and gaseous bodies filtering or flowing through interstices existing between the said lumps or pieces of solid substances. 2. The construction of apparatus, which provides for chloride of sodium or chloride of potassium in the state of vapour mixed with vapour of water, and mixed with gaseous products of the combustion of fuel, being caused to filter or flow at an intense heat through interstices existing between lumps or pieces of certain solid substances contained in a tower or chamber, as described. *Patent completed.*

2051. J. Willcock. *A new ornamental fabric, and the machinery for producing the same.* (A communication.) Dated July 18, 1862.

The subject matter of this invention relates, 1, to the manner of forming or making a new manufacture, to which the patentee has given the name of amosine braid, which is designed to be used either by itself or attached to other fabrics or tissues for ornament, or for other purposes to which it may be usefully applied. The mode by which he constructs this fabric is by a sewing machine, having the usual mechanism for forming a seam with any of the form of stitches usually employed in sewing machines, and in addition thereto, and in connection therewith, having certain machinery by which one or more threads, cords, braids, or other similar materials are interwoven with the sewing threads in a variety of ways, so as to form a kind of gimp, or braid, or fringe, by such interweaving, and also to sew the same on to the surface of cloth or other fabric in any desired line or figure by the same operation. One, two, or more of these embroidering threads or cords may be used of any desired size, colour, or material, and interwoven with the sewing threads in many forms. *Patent completed.*

2052. O. F. Morrill. *A certain new and useful apparatus for generating heat for culinary and various other purposes.* Dated July 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2053. F. S. Stott. *Improvements applicable to mechanism for warping yarns or threads.* Dated July 18, 1862.

This relates to that class of warping machinery known as warping mills, where hecks are employed, through the eyes of which the threads pass, being afterwards collected together in divisions termed tiers or half tiers, and to mechanism or arrangements for acting upon these divisions of threads when taking the lease, the object of this invention being to prevent the twisting of the tiers when passing on to the mill. The invention consists in modifying the forks which act upon the divisions of the threads when taking the lease, so that such forks will arrange the threads passing through or between their prongs, and cause the threads to be laid upon the mill taperwise, which is accomplished by constructing the forks with an inclined surface formed upon or applied to them at the bottom and between the two prongs of each fork, so that the threads as they pass between the prongs of the forks will come against the said inclined surfaces, and by this means will be placed parallel side by side, and thus the plane in which the threads are arranged will be changed from the horizontal to the vertical position, and in this position pass on to the mill. *Patent abandoned.*

2054. J. R. Abbott. *Improvements in sliding chandeliers, gaseliers, and other pendent lamps.* Dated July 18, 1862.

This consists in providing a means of sliding pendent lamps without taking the centre tube to the bottom of the pendent, so that the patentee can have a central light. This he effects in the following manner:—For making gas pendents upon the water slide principle, the centre tube is required to be only the length that may be necessary for the pendent to be lowered, and he uses four tubes in this case instead of three; the outer tube terminates at its upper end in a gas box or reservoir communicating with the pipes supplying gas to the burners. Inside this tube is fitted the usual hydraulic slide apparatus working through the gas box or reservoir before named, and furnished with its pulleys, chains, and balance-weights, the water cup being above the gas reservoir; inside these slide tubes is fitted the tube leading the gas from the main pipes. The gas passing down this tube rises upwards between the water slide and the outer or fourth tube into the reservoir, and thence down the supply pipes to the burners. In making pendents with the cork slides or stuffing boxes he requires only two tubes. The stuffing box is fixed either within the gas reservoir, or immediately in the top of it, so that it works up and down with the outside tube and the reservoir. For chandeliers and oil or other pendents than those used for gas, the same arrangement as that last described is employed, omitting the cork slide or stuffing box, which is only required for gas. *Patent completed.*

2055. J. S. Jarvis. *Improvements in shirt collars.* Dated July 18, 1862.

This invention is in the cut and make of the band of turn-down collars, whereby creasing or puckering of the outside of the collar is prevented. This invention is not described apart from the drawings. *Patent abandoned.*

2056. R. A. Brooman. *Improvements in generating heat in furnaces and fire places.* (A communication.) Dated July 18, 1862.

This invention consists in bringing superheated steam in contact with coal or other fuel in an incandescent state at any point in the fire above the grate bars. The superheated steam is not mixed with the atmospheric air of the blast or draught below the grate bars before coming in contact with the incandescent carbon. *Patent completed.*

2057. C. A. Day and T. Summers. *Improvements in sheer legs.* Dated July 18, 1862.

This invention consists, 1, in connecting the lower end of the back leg to a screw worm pinion and rack, hydraulic ram, or other like mechanical contrivance, for imparting to and fro motion to the back leg, in order that it may act as a prop to the front legs when they are moved inwards, and as a guy to them when they overhang outwards. The front legs are of the ordinary construction, and work in the usual manner. The invention also consists in the employment of a load at the lower end of the back leg. This loaded leg then acts to some extent as a back balance. *Patent completed.*

2058. A. B. Brown. *Improvements in steam-engines and boilers.* Dated July 19, 1862.

The patentee claims, 1, The construction and form of the expansion valves, as described. 2, The arrangement of the slot link, together with the friction sliding joint and lever, for the purpose of varying the travel of the subsidiary valve, as described. 3, The construction of annular water spaces around the smoke boxes or chambers of horizontal or locomotive boilers, through which the feed water is forced on its passage to the boiler, as described. 4, The construction of the doors of smoke-boxes with water spaces, through which the feed-water is forced on its passage to the boiler, as described. 5, The construction of a tubular hinge as a means of maintaining the calculations of the feed-water between the annular water-space of the smoke-boxes and that of the door, as described. *Patent completed.*

2059. G. J. Yates and J. W. W. Tindall. *A process of deodorizing paraffin, coal, pitch rock, and other like oils and hydro-carbons.* Dated July 19, 1862.

Here the patentee subjects the above-named oils to the action of sulphuric acid, nitric acid, urine, hydrochloric acid, chloride of lime, and fuller's earth. These various substances are added to the oil to be purified at certain definite periods of the operation, and when the oil is at the requisite temperature. *Patent completed.*

2060. R. Barrett. *Improvements in apparatus for working the damper of steam engine furnaces.* Dated July 19, 1262.

This invention is for improvements upon an invention for which letters patent were granted to Phillip Marcus, dated 14th March, 1856, No. 618, and consists in the employment of a double or compound lever, to the long arm of which the rod or attachment to the damper is connected in lieu of the simple lever described in the specification of the said letters patent. The invention further consists in placing the frame in which the bearings for the spindle of the damper are formed at an angle, and in bringing the base of the slot in which the spindle works into a horizontal plane or nearly so. And in order to render the working of the damper as easy as may be, the patentee brings the bearing or edge of the slots on which the spindle works, in the spindle itself, to a knife edge.

2061. R. A. Brooman. *Improvements in revivifying animal black and in apparatus employed therein, and in recovering a product employed in the revivification.* (A communication.) Dated July 19, 1862.

This invention is for improvements upon a former invention for which letters patent were granted to the present patentee, in consequence of a communication from the said Leplay and Cuisinier, the 31st December, 1861, No. 3275. The invention consists in treating animal black as hereafter explained in a series of revivifying cylinders, by preference, four in number. as hereafter stated. Each cylinder contains a perforated false bottom for permitting the inlet of steam from a steam supply pipe; each cylinder communicates with that next to it by a pipe extending from beneath the perforated false bottom of one to the upper part of the next. There is also a pipe leading directly from the upper part of the first cylinder to the lower part of the last in the series. The animal black to be operated on is washed with hot water before being placed in the cylinders; steam is admitted. through the perforated false bottom in the first cylinder, and a solution of caustic soda in a boiling state is admitted at the top of the cylinder; the steam meeting the solution of caustic soda, causes a tribbling and agitating action, and a general motion of all the particles of black; the caustic soda solution being continued to be added, passes into the second, third, and finally into the last cylinder in the series; when the action has been continued long enough in the first cylinder the admission of caustic soda is prevented, and communication closed to the next cylinder. Hot water is now admitted, then hydrochloric acid, after which a solution of biphosphate of lime, then water to wash the black. The black is now completely revivified, is withdrawn, and dried. The like process is continued in all the other cylinders, and finally the caustic soda is made to deposit in the last cylinder in the series. The caustic soda is fully charged with colouring matter from the black, and is drawn off into a separate vessel where it is evaporated. It is next removed in a dry state, and is treated with nitrate of soda under heat, which, driving off the colouring matter, leaves caustic soda. *Patent completed.*

2032. A. Cotille. *Improvements in the manufacture of alcohol.* Dated July 19, 1863.

This invention consists in a process for manufacturing alcohol by means of its component parts, bicarbonated hydrogen (defiant gas) and water. *Patent completed.*

2063. A. Pratt. *Improvements in self-acting firerrms* Dated July 19, 1862.

This consists in improved arrangments in connection with fire-arms, by which the nipple may be capped by the action of the lock when raising the hammer to full cock. *Patent completed.*

2064. W. E. Newton. *Improvements in ordnance and projectiles for the same.* (A communication.) Dated July 19, 1862.

Here the patentee uses, in combination with a hollow core a casing of molten metal whereby he retards the cooling of the exterior of the piece of ordnance to be cast. The same method is adopted in casting round shot. The invention also consists in the use of elongated projectiles of much smaller calibre than that of the gun from which they are to be fired. A sabat and guide band are used to centre the projectile in the gun, the sabat presenting a base to the pressure of the gases of an area equal to the area of the calibre of the gun. To reduce the resistance of the atmosphere to the flight of the projectile the patentee fits to such projectile a point of lead of conical, conoidal, or other such form. *Patent completed.*

2065. W. E. Newton. *Improvements in machinery for preparing fibrous substances for combing.* (A communication.) Dated July 19, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2066. T. H. Saunders and J. Millbourn. *Improvements in the manufacture of paper.* Dated July 19, 1862.

This relates to an improved mode of drying paper as it comes from the machine, and previous to its being introduced to the sizing vat. The patentees have found that, by the paper being carried along in contact with heated rollers or cylinders, its texture or strength is somewhat improved, and for this reason machine-made paper is always inferior in quality to hand-made, which is what is termed air dried, the sheets being hung up on lines to dry by contact with the air. In order to air dry machine-made paper, instead of drying the paper by bringing it into contact with heated rollers, as heretofore, they cause the paper to pass from the machine over or round a series of skeleton drums or frames, totating or otherwise, and during its passage they submit the paper to currents of air which will carry off the moisture without impairing the solidity or strength of the paper, as is the case when the paper is dried by heated cylinders. This improved mode of drying paper is applicable to engine sized paper, as well as to paper which is sized in the machine at a subsequent stage. *Patent completed.*

2067. W. Tranter. *Improvements in firearms.* Dated July 19, 1862.

This consists, 1, in the use of a stop or holder for the revolving chamber, in the form of a spring lever, with a hooked end adapted to be acted upon by a tooth or projection on the front of the tumbler or hammer, when the latter is raised previous to firing, thereby withdrawing the stop and liberating the chamber, the spring of the lever forcing forward the usual stud, and locking the chamber, when the tooth or projection on the tumbler or the hammer has passed out of the hooked end of the lever. 2, In the use of a bridle or cover for the works of a revolver, which may be removed with facility, so as to admit of the works being examined as required. 3, In the use of a centre rod for the chamber to revolve on, with a spring or spring lever acting in a slot or cavity in the rod, which spring, on being compressed into the cavity, allows the rod to be withdrawn from the body, in order to take out the chamber when required. There is also a slot or cavity in the frame, into which the spring of the rod passes, whereby the rod is held firmly in its position. 4, In adapting and applying to ramrods a lubricating brush, or elastic fabric, or substance, capable of holding lubricating material for lubricating the inside of the rifled barrel each time it is boarded. 5, In forming the grooves of rifle barrels in the shape of a hyperbolic curve, for the purpose of getting rid of angles in the cross sections so as admit of the lubricating rod cleaning the barrel or softening the deposit therein with facility. *Patent completed.*

2068. C. Ramsay. *An improved military cloak.* Dated July 21, 1862.

This consists in making a cloak in the following manner, that is to say:—The body of the cloak is cut nearly circular, and has a hood affixed to the neck part thereof; a loose cape is also intended to be connected when desired to the neck part of the cloak by buttons and button holes; sleeves are also sewn to the cloak to receive the arms of the wearer. A cloak thus formed makes an excellent tent either for soldiers or civilians. *Patent abandoned.*

2069. J. W. Green. *Improved method of cutting sheet and plate glass to any given design, giving the finished form the brightest polish possible.* A communication.) Dated July 21, 1862.

This consists in subjecting the sheet plates and other glass to a graduated heat in an oven (muffle oven) especially constructed. The glass is kept in this oven until it becomes softened; then it is placed into a draught oven (zug oven) where a great heat is obtained by a bellows; the glass is then put between a lever, which is so constructed as to cut the rough edges clearly off, leaving the article so pressed of the finest polish and finish. The dies are so arranged as to cut and press the glass when of various constructed thicknesses. When the glass is cut and pressed, it must be gradually cooled. Glass manipulated on this principle shows a higher degree of polish than by other methods. *Patent abandoned.*

2070. E. Bazin. *An electric railway carriage signal.* Dated July 21, 1862.

The main feature of this invention consists in galvanizing or coating the coupling chains with zinc, whereby electric communication is produced throughout a train for the purpose of striking an alarm bell or sounding plate placed near the engine-driver. *Patent completed.*

2071. W. E. Gedge. *Improved excavating or boring apparatus.* (A communication). Dated July 21, 1862.

This consists in making a hole by ordinary means in any body of material, and introducing therein an instrument which, by its action, will form an inner cavity of larger diameter than that of the primitive. The invention is especially applicable to blasting. *Patent completed.*

2072. T. Davey. *Improvements in the manufacture of gunpowder and explosive compounds.* Dated July 21, 1862.

The patentee claims, 1, the mixture with ordinary gunpowder materials in the course of manufacture of starch, dextrine, gum, flour, or sugar, prepared as described with nitric acid, or nitric and sulpheric acids combined. 2. The manufacture of gunpowder, or other explosive compounds, into tubes, or hollow pieces, or grains. 3. The use of paraffin, turpentine, naptha, or other suitable hydrocarbon in the manufacture of gunpowder and explosive compounds. *Patent completed.*

2073. A. M. Fell. *Improvements in obtaining or manufacturing sulphate of ammonia and manure.* Dated July 21, 1862.

This consists in using matters arising in the distillation of oil from bituminous schales or schists. When the bituminous matter is distilled, there comes over from the retorts along with the oil a large proportion of ammoniacal liquor of water, which, after separation from the oil, is put into a vessel and has sulphuric acid added to it until it is ascertained by the ordinary tests that all the ammonia has combined with the sulphur. The resulting liquid is then put into a suitable pan and evaporated to dryness, the dry residuum being sulphate of ammonia. The manure is obtained by mixing the sulphate of ammonia with the matters remaining in the retort when the distillation is completed. *Patent abandoned.*

2074. A. Naudain, J. Peacock, and W. H. Walton. *Weaving, being an improvement in looms for weaving all kinds of textile fabrics.* Dated July 21, 1862.

This consists in weaving fabrics in a circle, or any part of a circle, and in using a plurality of shuttle passing through a warp or web at the same time, and in carrying the shuttle or shuttles through the warp by means of friction rollers, pulleys, or belt, or their equivalents, and by heating up the weft or filling in sections. *Patent abandoned.*

2075. W. Clark. *An improved pomade or balsam termed "Balsam Achille."* (A communication). Dated July 21, 1862.

This balsam or pomade is made of resin and galipot, white fat, and suet, virgin and yellow wax, fine olive oil, camphor, white soap, benzoin, spirits of wine, and essence of lavender. The above matters are mixed together, the solids being dissolved in the liquids so as to form a homogeneous composition. This odoriferous cosmetic is first melted and then applied by friction. *Patent completed.*

2076. A. Phillips. *Improvements in looms for weaving figured fabrics.* Dated July 21, 1862.

This refers to a previous patent, dated 18th July, 1859, (No. 1694). In this invention the looped or velvet pile surface of the fabric is formed wholly of the weft, which is bound in by a secondary or binding weft. The present invention comprehends an improved arrangement of the weaving mechanism, so as to accomplish a similar result with simpler but more efficient means. *Patent abandoned.*

2077. T. Meriton. *Improvements in steam-engine governors and speed regulators for machinery.* Dated July 22, 1862.

This relates to the fly wheel governor, and the invention consists partly in simplifying this form of governor, by dispensing with superflous parts, thereby effecting economy in first cost, but mainly in rendering more certain, prompt, and efficient its action by improved construction, arrangement, and disposition of parts. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated Oct. 18, 1862.

2816. W. E. Gedge, 11, Wellington-street, Strand. An improved apparatus for extracting condensed steam. (A communication.)

Dated Nov. 27, 1862.

3182. J. L. Linton, Buckingham Palace Hotel, Buckingham-gate. Improvements in the means of generating steam, and in the apparatus to be employed therein. (A communication.)

Dated Jan. 9, 1863.

76. E. A. Goupil, 10, Rue d'Hauteville, Paris, gentleman. An improved locomotive apparatus.

Dated Jan. 13, 1863.

102. T. Boyle. Gray's Inn-terrace, glass silverer. A new apparatus for multiplying indefinitely the reflections of all objects that are capable of being viewed in it.

Dated Jan. 15, 1863.

131. T. C. Barraclough, Manchester, engineer. An improved alarum apparatus, which may be employed in connection with locks or other fastenings. (A communication.)

132. J. Harrop, Manchester, analytical chemist. Improvements in the treatment of organic fecal and urinous matters for the purpose of deodorizing the same, and in the preparation of a portable manure therefrom, and in the treatment of ashes, or other refuse of combustion, to be combined therewith, also for improvements in machinery be employed in the manufacture of the said manure.

134. R. Ferrier, gas engineer, Edinburgh. Improvements in wet gas meters.

Dated Jan. 16, 1863.

144. J. Kerr, Manchester, painter. Certain improvements in the means of retarding or stopping railway and other carriages.

Dated Jan. 17, 1863.

150. J. Edwards, 29, Basinghall-street. Improvements in the manufacture of buttons.

156. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the manufacture of buttons. (A communication.)

Dated Jan. 19, 1863.

158. C. Norton, 47, Hawley-road. A new or improved method of roughing horses.

164. J. J. Lundy, Leith, colour manufacturer. Improvements in the manufacture of metallic casks and vessels.

Dated Jan. 22, 1863.

198. J. M. Binger, Brussels, gentleman. An improved paste, or composition, to cover the rollers used by letter-press printers.

Dated Jan. 23, 1863.

206. J. Milner, 7, Bridge-street, Westminster. Improvements in steam engines.

208. E. Strangman, Waterford, Ireland. Improvements in pipes for smoking tobacco.

212. P. A. Cole, Croydon-street, civil engineer. Improvements in the articles of dress known as collars, cuffs, wristbands, shirt-fronts, habit-shirts, and petticoats.

214. E. T. Hughes, 123, Chancery-lane. Improvements in breech-loading firearms. (A communication.)

Dated Jan. 24, 1863.

216. W. Mellor, Ardwick, and W. Whaley, Rainow, Chester, tool makers. Improvements in steam hammers and other engines driven by steam.

220. M. A. F. Mennons, Rue de Dunkerque, Paris. Improvements in machinery for punching and cutting metals. (A communication.)

222. A. J. Sax, Paris, musical instrument maker. Improvements in rendering drum-skins and gut-strings less liable to hygrometric influences.

224. F. Tolhausen, Rue de Faubourg, Montmartre, Paris. Improvements in looms for weaving ribbons. (A communication.)

Dated Jan. 27, 1863.

236. C. Askew, Charles-street, Hampstead-road, engineer. An improved railway chair and joint for rails on railways.

238. R. A. W. Green, Putney, boat builder. Improvements in light rowing boats, usually termed wager boats.

242. W. C. Wilkins, Long-acre, lighthouse engineer. Improvements in lamps.

Dated Jan. 28, 1863.

244. H. Watson, Renton, brick builder. Improvements in the heating arrangements of stoves for drying woven fabrics.

246. W. E. Gedge, 11, Wellington-street, Strand. Improved machinery or apparatus for fastening, by screws, boots, shoes, and other articles composed of leather. (A communication.)

248. J. Oglesby, J. Dickinson, W. M. Dickinson, and J. Dickinson, York. Improvements in apparatus for steaming, cooking, and generating gas.

250. C. Mace, Sunderland, practical engineer. Improvements in steam engines for propelling engines, and for other purposes.

252. F. W. Wymer, engineer, 7, St. Ann's-row, Newcastle-on-Tyne. Improvements in steam engines.

254. W. Conisbee, 39 and 40, Herbert's-buildings, Waterloo-road. Improvements in cylindrical chromo-lithographic printing machines.

256. W. Clark, 53, Chancery-lane, engineer. Improvements in the means and apparatus for copying and reproducing sculpture and other objects of art. (A communication.)

258. C. P. Stewart and J. Robinson, Atlas Works, Manchester, engineers. Improvements in and applicable to that apparatus known as Giffard's injector, and in the adaptation of it to locomotive and other boilers.

260. H. Crichley, Birmingham, ironfounder. Improvements in reaping and mowing machines. (A communication.)

Dated Jan. 29, 1863.

266. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of candles. (A communication.)

268. W. Ball and J. Wilkins, Nottingham. Improvements in machinery employed in the manufacture of looped fabrics.

270. N. Clayton and J. Shuttleworth, Stamp End Works Lincoln. Improvements in thrashing machines.

272. A. Pritchard, Derby, black lead manufacturer. An improved method of preserving the contents of packages from air, water, or damp.

274. W. Clark, 53, Chancery-lane, engineer. Improvements in the condensation of steam, and in apparatus for the same. (A communication.)

INVENTIONS PROTECTED FOR SIX MONTHS BY THE DEPOSIT OF COMPLETE SPECIFICATIONS.

Dated Jan. 9, 1863.

262. H. A. Bonneville, 24, Rue du Mont Thabor, Paris. Improvements in the construction of granaries. (A communication.)

265. J. Mackenzie, Arundel-square, Islington, engineer. Improvements in shaping machines for curvilinear surfaces.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, Feb. 10, 1863.

2640. W. B. Lord and F. H. Gilbart. Loading firearms, and in blasting.

2654. A. Prince. Manufacture of varnish, printing-ink, paint, and printing colours. (A communication.)

2664. W. C. Wilkins. Gas burners.

2671. R. Broadbent. Gas regulators.

2675. A. Dalrymple. Processes of depositing metals by galvanic action.

2680. A. Barclay. Printing textile materials and fabrics.

2681. W. E. Gedge. Improved means or apparatus, by the use of which pieced or perforated cocoons may be spun. (A communication.)

2683. J. E. Billups. Fixed points for railways.

2686. F. Watkins. Milking cows.

2687. F. E. Blatspiel. Diving apparatus. (A communication.)

2688. W. Clark. Preserving goods from fire. (A communication.)

2690. F. Johnson. Fire-escapes.

2696. S. Holland. Manufacture of bricks.

2699. T. Beards. Cultivating land.

2700. S. F. Cox. Washing and tanning hides and skins.

2713. A. V. Newton. Condensers or coolers. (A communication.)

2726. J. H. Johnson. Manufacture of paints or pigments. (A communication.)

2746. J. Durrant. Form and construction of chimney tops.

2749. A. V. Newton. Sewing machines. (A communication.)

2750. S. Chatwood. Fire and thief-proof depositories.

2753. G. Haseltine. Jacks and screw nuts. (A communication.)

2757. W. G. Haig. Apparel.

2758. J. Gumbley. Break for vehicles.

2784. J. B. G. M. F. Piret. Lubricating apparatus.

2815. J. Fuller. Treating india-rubber used on a wire or wires for insulating the same.

2821. J. Clark. Applying railway brakes.

2842. J. Spencer. Non-conducting compositions.

2903. E. S. Tudor. Purification of lead.

2906. T. Sutton. Preparing albumenized paper for photographic purposes.

3102. J. Oxley. Separating liquids from substances.

3164. G. Ranson. Preparing clay for brickmaking and other purposes.

3264. T. E. Blackwell. Barometers.

3284. J. Sellars. Manufacture of pulp.

3338. E. Thorold. Drill braces.

3418. M. Clark. Treating waste liquors.

3443. E. Stevens. Preparing dough and paste.

3483. F. Applegate. Manufacture of a kind of woollen cloth.

16. A. Bamford, R. Blomley, R. Taylor, and J. Lett. Looms for weaving.

73. W. H. Tucker. Locks.

93. E. D. Chattaway. Railway signals.

131. T. C. Barraclough. Alarum apparatus. (A communication.)

133. G. Graham and J. McLeod. Turkey-red dyeing.

144. J. Kerr. Retarding or stopping carriages.

208. E. Strangman. Pipes for smoking tobacco.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Feb. 6, 1863.

2231. Sir J. S. Lillie.
2233. A. J. Moreau and A. E. Ragon.
2234. A. J. Moreau and A. E. Ragon.
2235. T. De la Rue.
2244. J. Lancelot.
2246. W. E. Gedge.
2249. A. J. Martin, J. Goss, and J. Bush.
2257. A. Delrue.
2258. C. M. Westmacott.
2261. A. B. Childs.
2269. J. R. Tussaud and F. C. Tussaud.
2292. J. Hearn.
2313. F. Barnett.
2375. W. H. Turner.
2531. J. Pender.
2957. G. Haseltine.

Sealed Feb. 10, 1863.

2262. C. Sengry.
2263. G. Sanders.
2271. W. L. Boyle.
2273. H. Twelvetrees.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office, 25, Southampton-buildings, Chancery-lane.

LONDON, FRIDAY, FEBRUARY 20, 1863.

SIR WILLIAM ARMSTRONG.

Sir William Armstrong has just resigned a post he should never have occupied; and it will, perhaps, for some time remain an unsolved problem why he occupied the post so long. Being a man of great firmness and tenacity of purpose, he held on till the last, and it was only when he saw the rising wave threatening to engulf him, that he surrendered. His position has for some time past been as untenable as his much vaunted gun has been imperfect. We have so frequently criticized his gun that it is needless to do so now; and we have several times pointed out the unreasonableness and injustice of a man being a public servant, and, at the same time, a sleeping partner in a large manufactory, where tens of thousands of pounds of the public money were being annually expended. Sir William being an inventor of rifled artillery, and being, as a matter of course, prejudiced in favour of his own invention, did his best to keep other artillerists in the back ground, and, as an equal matter of course, used all his official influence to send grist to the Elswick mill. His position was so anomalous—we may say preposterous—that it is unaccountable that the British public permitted itself to be trifled with so long in the matter. And, perhaps, the most remarkable thing of all has been that Armstrong guns have been made at least a third part cheaper at Woolwich than at Elswick. Government establishments are famed for their wastefulness and extravagance, and private firms have been extolled for economical production. But in this Armstrong gun business we have not only seen the inventor made the official, but the official permitted to have an interest in an establishment where his own gun was made at a much greater cost to the nation than if it had been made under the superintendence of Mr. Anderson, at Woolwich. Knowing these facts, we have not hesitated to say that the whole affair has been the most gigantic job of the nineteenth century, and future historians will refer to it as an instance of the immorality of our official life, and the stupidity of the public. People will wonder how Sir Wm. Armstrong attained his position and maintained it so long.

We will give one or two reasons. The Armstrong gun was brought before the public just after the Crimean war, when it was supposed by many people, in this and other countries, that our military strength had suffered something like a collapse. Something was wanted to re-establish confidence; and it was found in the estimation of some in the Armstrong gun. The virtues of the gun were blazoned by the press. England, it was stated, had found a weapon that would make her all-powerful on land and sea. Sir William being an able diplomatist—in fact one of the ablest diplomatists living—took advantage of the opportunity. He managed to get the *Times* and other public organs on his side. He whispered in the ear of Sir Benjamin Hawes, then Under Secretary of War, and secured his support. Sir Benjamin married a sister of the younger Brunel. By a nice little diplomatic arrangement, we find Brunel's son made a *partner* in the Elswick firm. And so the influence of Sir Benjamin was obtained and secured, partly, no doubt, through his social affections. A master bit of policy this! We believe we are right in stating that Sir Benjamin was trustee of the late Mr. Rendel, C.E., whose son was made another partner of the Elswick firm. Sir William having the ear of the Government through Sir Benjamin Hawes, and possessing the power to inspire the press, became master of the situation. Million after million of the public money was voted, year after year, for the Armstrong ordnance. Elswick was in full feather. England was becoming possessed of a matchless weapon that would defy the world in arms. During this period of prosperity and triumph one small voice endeavoured to make itself heard above the bustle and din of military preparation. The Mechanics' Magazine analysed the gun and the projectiles made for it, and stated that they could not possibly remain long in her Majesty's service. The same small voice that spoke of the inherent deficiencies of the weapon, questioned the peculiar position occupied by its inventor, and condemned the extravagant price paid for the new system of artillery. Occasionally, Sir William would appear in the columns of the *Times*, denying our allegations, and vindicated his system with polished rhetoric. But neither his diplomatic tact, his eloquence, his industry, nor his tenacity, could avail against the truth. His resignation, whatever may be said to the contrary, is a virtual abdication of power, and the Armstrong gun, which has been so vastly praised by so many tongues and pens, will figure only insignificantly in our artillery annals. Perhaps many, who at first doubted our sincerity or our science, will, in future, give us credit for possessing a little of both.

HARBOURS OF REFUGE.

The reply of the Duke of Somerset last week to Lord Ravensworth's inquiry whether any steps were in progress to carry out the recommendations of the Royal Commission, with respect to the formation of harbours of refuge, re-opens the whole question, and undoes all that has been done during the last ten years. We are brought back to the point we started from, and doubts are intimated that harbours of refuge are not necessary or even desirable for the preserving of life from shipwreck on our coasts. This is really most disheartening. It seems as if no public question can be solved openly and on its own merits, but must be determined by personal considerations, and that the saving of money is to be preferred to the saving of life.

The First Lord of the Admiralty stated the case very fairly, and pointed out how the local authorities are all willing to have harbours constructed, on condition that they are not to be called upon to contribute a fraction towards the cost. But we think he was in error in some of his conclusions. He expressed his belief that it would be a great mistake to make a great many harbours along the coast, as the commissioners recommended; and that no such a saving of life and property, as some people anticipated, would be effected by them; for all the evidence taken on the subject showed that, on the contrary, they would lead to persons continuing to employ very unseaworthy and badly found ships. In the first place, we do not perceive how the number of harbours, which the commissioners recommended should be formed, can be called a "great many," seeing that the total was no more than ten—namely, two on the north-east coast of Scotland, and three on the north-east coast of England; one at the Isle of Man, two on the Irish coast, and two in the Bristol Channel, or rather on the north Cornish coast; but of these ten four—Wick, Peterhead, Waterford, and Tyne river—are trading harbours. When we consider the length of coast, on which no shelter is to be found, ten harbours cannot be termed a great many, and still less so if we cast our eyes on the wreck chart, and note how many ships have been lost between the sites where it is proposed to erect them and existing harbours. Their cost, estimated at four millions, is a far more formidable objection, though the commissioners proposed the public grant should be limited to £2,365,000, and the remainder, £1,625,000, to be raised in the localities. Mr. Wilson's Select Committee proposed fewer harbours, at half the cost, but among them were two which the subsequent Royal Commission rejected, viz., at the Mumbles, and at the Skerries, so that the number would be reduced to one-half, and the cost to £1,600,000. Among these were harbours at the points where they are most needed.

The part of the Duke of Somerset's reply, which stated that harbours of refuge would not preserve so many lives and so much property from shipwreck as was anticipated, if taken in connection with what was said by Mr. Milner Gibson in the House of Commons last session, and with what Lord Ravensworth stated about the apathy of shipowners, and their fear that harbours would induce crews to loiter on insufficient grounds, leads to the inference that Government are not so convinced of the usefulness of these works of shelter as it was imagined they were. They appear to attach more importance to the individual opinions of certain shipowners than is warranted by the general tenor of evidence taken before the Select Committee and Royal Commission. Mr. Allan Gilmour, of Glasgow, one of the largest shipowners in the country, was of opinion that harbours of refuge, marked down as such, are the means of causing loss of life and property rather than of saving them, by inducing captains to run down to them instead of keeping the open sea. Accordingly his captains were instructed, in case of accident, to return to the port of departure, and by all means to keep the sea—not run for a harbour of refuge. The result of this policy has been, that out of his numerous ships, which, during twenty years, made upwards of 1,700 voyages to all parts of the world, he lost ten only, and not one of them on the British coasts. This fact speaks rather in favour of the admirable organization and careful supervision of Mr. Gilmour's service than of the inutility of harbours of refuge. At all events, he did not find many men in his town to support his views. True, Mr. Allan, owning a fine fleet of sailers and steamers, and who had been eighteen years at sea in all grades, from apprentice to master, thought harbours useless, except on the east coast of Scotland, and for one there he would not object to contribute his quota of taxation, if the work were judiciously and properly done. So that after all his opinion amounts to this, that harbours of refuge are useless where they are not wanted—a very logical conclusion, from which he will find few to dissent. The rest of the witnesses were strongly in favour of creating places of shelter, but more especially seafaring men. At Dundee, one witness believed that harbours would not save lives, though he had admitted having occasionally resorted to them under stress of weather, consequently, his experience negatived his belief. Of the hundreds of witnesses who have been examined during the years the question was being investigated, these were the only three that expressed doubts of the utility of harbours of refuge, and of their conducing to the preservation of life and property from shipwreck. The evidence on the other side was overwhelming—from seamen, shipowners, fishermen, naval officers, merchants, and, indeed, all that are in any way connected with the sea. The Liverpool Mercantile Marine Association, composed of 800 members, sent their secretary before the commission to say that they considered it "not merely a shipowners' question, but a question affecting the lives of masters, officers, and seamen." Mr. Langton, as the representative of the Liverpool underwriters, declared that they considered the establishment of harbours of refuge would be advantageous to the protection of their interests, and likewise for the protection of life and property. The Hull Chamber of Commerce presented a memorial, setting forth that the members considered the question one of great importance, and the South Shields' seamen petitioned for the establishment of a harbour on the north-east coast. It would be easy to multiply evidence of the same description; but we have preferred to take that which was afforded by large representative bodies, who cannot be accused of having any local interest, and who advocate the establishment of harbours of refuge on their intrinsic merits, and because of the public good they will effect. The reader will probably be satisfied, from what has already been said, that the preponderating weight of testimony is against Mr. Gilmour's proposition, which Government seems disposed to entertain, and we confess to be unable to discover upon what grounds they can justify the reopening of the question.

The Duke of Somerset alluded to the harbours in the course of construction, and expressed an unwillingness that Parliament should incur fresh expenditure until they were finished. But it is an error to speak of these works as harbours of refuge, with the exception of Holyhead and Portland, for they are quite useless as places of shelter, and were expressly designed for military purposes. No ship would go into Dover; but into the Downs in case of stress of weather. The works of Harwich were confined to deepening the Channel that it might serve as a port of call should war ever occur in the North Sea. Alderney and Jersey are both out of the track of ships going up or down Channel. Even Portland is being transformed into a fortified naval station to rival and neutralise Cherbourg; and Holyhead was undertaken for the convenience of the Irish mail, so that in reality we have not a single *bona fide* harbour of refuge; for a shelter of this kind, being for the benefit of all nations, should be exempt from attack in war as lighthouses are, and consequently be left undefended.

The imputation cast by the Duke of Somerset upon certain persons in the coal trade—that send old ships to sea which are fit for nothing—is most discreditable to them. If anything, Lord Ravensworth's apology makes it worse. He says that, stripped of every rag of protection, they are compelled to compete on their own shore with foreign ships, navigated, equipped, and built cheaper than English colliers, and, therefore, that it ought not to excite surprise if the owners of the latter, in order to be able to carry on competition, send ships to sea badly found and not fully manned. Never was a lamer or more infamous excuse proffered, and that any English gentleman could have been found to utter it, is a marvel of the times, only to be equalled by the fact that not one among the peers who had heard this barbarous, un-English, and un-Christian doctrine, had the courage to protest against it. Were the same thing done ashore by an employer of labour, he would be tried for manslaughter, perhaps for his life. If a railway company were to plead such an excuse, Lord Camphell's Act would teach them what it cost in purse to neglect proper precautions, and to risk life to be able to carry on competition. The Duke said harbours of refuge would induce coal shipowners to persevere in this system. It is impossible to discover the train of reasoning by which he arrives at this conclusion, or to find, in the half-dozen volumes of Parliamentary reports on the subject, any trace of evidence to that effect. We are told of ships being sent to sea with timbers rotten, and sails so worn as to be blown from the yards in the first gale of wind; and of other vessels so bad that no crew could be found to ship in them; but not a word that the provision of places of shelter would make matters worse.

From the whole tenor of the First Lord's speech, it is to be gathered that Government have determined to defer commencing the construction of harbours of refuge, and to wait to see how Mr. Milner Gibson's Act of last session operates, to the improvement of trading harbours, by means of advances from the Public Loan Commissioners, for carrying out works under local direction. The scheme is certainly an admirable one, and appears, up to the present time, to have been successful.

THE ATLANTIC CABLE.

TO THE EDITOR OF THE MECHANICS' MAGAZINE.

SIR,—The fact of two papers having been read before the Society of Arts, followed by important discussions, joined in by some of the most eminent men connected with telegraphy, together with the proposition of Sir Edward Belcher, that the society should appoint a committee for the further consideration thereof, in order to elucidate all possible information to the end that satisfactory data may be afforded which shall place the construction, submergence, and successful working of all future submarine cables beyond the possibility of failure, is significant of the importance the second proposed Atlantic cable holds in public estimation.

This is as it should be; too much light cannot possibly be thrown on a matter of such importance, affecting as it does the interests, and probably the destinies of the Old and New Worlds—presuming that the scientific consulting committee of the Atlantic Telegraph Company are not too wise in their own conceit to profit by and adopt conclusions which are incontestably established beyond the power of refutation, as well as others which are in a fair way of receiving a solution. We are justified in entertaining a little trepidation on this point—in assuming that prejudice, foregone conclusions, and other causes which shall be nameless, because they suggest themselves, will retain their obstructive shapes; therefore we cannot be over sanguine that the beneficial results of "more light" will receive that appreciation at the hands of the gentlemen in question which they ought to receive. The past justifies it, present operations confirm it, and the future is not devoid of cause for misgivings.

The failure of the Atlantic cable resulted in the appointment of a commission by Government to sift the whole matter of ocean telegraphy in every sense of the word;—the best mode of constructing a cable so as to meet the highest scientific requirements, as well as the best route, mode of submersion, and, indeed, everything that in the remotest degree appertained to the subject. The result was a blue book of more than ordinary dimensions, to which universal testimony has been borne as to its comprehensiveness, the soundness of its conclusions, and the incalculable service it has rendered to the general subject of telegraphy; and further, that it completely and satisfactorily solved the problem of the feasibility of long lines of deep sea cables. The propositions therein laid down may be considered the electric and telegraphic articles of faith of this committee and of all advanced telegraphists; not, indeed, the ultimate good, the *ne plus ultra*, but certainly a far advanced stage from which it were little short of criminal to recede, and which, if acted upon, would infallibly ensure success.

During the two years over which this committee extended its sittings, thousands of experiments were made, and almost every individual at all acquainted with the subject—manufacturers, electricians, telegraph engineers, patentees of insulating substances, instrument makers, theorizers, and practical men — were examined before it, and their separate evidences are to be found in its pages. Truly, the Government, and the committee also, were thoroughly imbued with a sense of the importance and stupendousness of the matter they thus took in hand; hence the length of its sittings, and also its completeness and comprehensiveness. Probably no Government committee of modern times ever had so important an inquiry entrusted to them, nor one so difficult of comprehension, nor from the mass of conflicting evidence, opposing theories, and petty interests of the examiners—one in which the tasks of arriving at sound, independent, and logical conclusions, was attended with so much anxious labour and deliberation; so much more is it to their honour, therefore, that without leaning to this or that theory, or the favouring of this or that interest, they steered clear of all, and arrived at the only conclusions to which honest and impartial men could come. They have their reward in that their labour has been appreciated by the foremost men of the age, both in England and on the continent; nor does the country begrudge the expense of this commission, which, of course, was something considerable. Yet, notwithstanding all this, one is almost tempted to exclaim that this committee might almost as well not have been appointed, seeing that its most important conclusions have been ignored by those who should have set a practical example of appreciation thereof to all the world. I refer to the promoters of the Persian Gulf cable, which, notwithstanding the assertion of the *Times*, that in its design the "recent improvements in the science of telegraphy have been taken advantage of," and notwithstanding official oracles claim for it a prospective superiority of 25 per cent. over all others, by virtue, we are led to suppose, that the Government has not "given over this great national work, to any company, contractor, or concessionaire;" the glaring fact stands out unmistakeably that this cable, in all the details of its structure, from the most important down to the most trifling, is an absolute departure from every recommendation made by the Government committee, and is as far removed from what a submarine cable (especially for the tropics) ought to be as the North is from the South. The advantages which its sectional solid conductor is said to possess over a solid one only, are purely gratuitous, and founded only on supposition, while its disadvantages, as compared with the latter, and its immeasurable inferiority to a stranded conductor, will be apparent to every one who gives the matter a little careful consideration. Its insulation of alternate layers of gutta-percha and Chatterton's compound is the worst that could have been devised; the latter is said to contain resin; and therefore has a most pernicious influence on the former; add to which the inefficiency of gutta-percha as an insulator, and its notorious inadaptibility for warm climates; and this course has been taken by Government itself after its committee had indorsed the dictum of the superiority of caoutchouc! Lastly, its outer sheathing is also entirely at variance with the teaching of the blue book; for that which is to guard from danger the precious charge within is itself the source from whence peril emanates to the core; protection by such means is well nigh an exploded fallacy; the core is better free from the embrace of so dangerous a neighbour, and can better take care of itself.

With such an instance of suicidal departure from the teachings of experience, and such a wholesale setting at nought by the India Board of the results of the grave deliberations of the Government committee, we turn our attention prospectively with but little confidence to the intentions of the Atlantic Telegraph Company. True, we have the authority of the Right Hon. Stuart Wortley, that the scientific committee appointed will ensure a cable which shall combine the results of the most advanced scientific acquirements, practical skill, and every other knowledge appertaining to the manufacture and submergence of a cable. And we have also his reiterated assurance that the company is free and unshackled to choose whatsoever cable they will; and it would ill become us to call into question his veracity; nevertheless, we have a right; and it is our duty to ascertain how far these statements are likely to be borne out by facts; and in order to do this, we will take the case of the company on its own grounds, and will not attempt to call into question whether theirs is or is not the best route that could have been selected. And further, we wish it to be understood, that our notions of a good cable are the results of actual experiment, coinciding with the opinions of that committee of which the chairman of the Atlantic Telegraph Company was so distinguished a member. The unusual prominence given to submarine telegraphy of late, is evidently mainly due to the exertions of this company to carry out their undertaking; and, doubtless, we all rejoice in the confident hope that they will be able to do so. The paper read before the Society of Arts, by Mr. Masey, unquestionably received its inspiration from Old Broad-street, and, therefore, to a certain extent, we may consider that it embodied the ideas of the Atlantic Company. As to the character of the cable that would probably be fixed upon, and also as to the general intentions of the company, this, therefore, with certain remarks made by other gentlemen similarly connected, in the two nights discussion which ensued upon that paper, will afford good grounds for the following remarks; also in connection therewith let us not forget the statement made by Mr. Stuart Wortley, at Liverpool, a short time since, that the "manufacture of the new cable would be submitted to the widest competition." It is a remarkable fact, that in all this lengthened and important debate, the comparative merits of gutta-percha and india-rubber were never discussed; every other imaginable topic connected therewith, from marine animalculæ, who were specially created to prey upon submarine cables, to the influence of the *aurora borealis,* all things relevant and irrelevant, received due share of attention, and more. But this, *the* most important point of all, was all but utterly ignored. Mr. Masey disposed of the whole matter in one short paragraph, unwittingly including therein the quintessence of the Government committee's deliberations on insulation, and therefore upsetting entirely the conclusion to which he most unaccountably arrived, thus betraying either a total ignorance of the nature of india-rubber, or prejudice, or both combined. We are told in the same breath that it is not durable, and that we are not possessed of sufficient data to warrant its use (!) both of which statements have been satisfactorily refuted over and over again; and therefore it is the more astonishing that any man should commit himself to allegations which the history of caoutchouc, long before gutta-percha was discovered, proves both fallacious and absurd. Without disparaging gutta-percha, we may fearlessly assert, that there is no substance derived from the vegetable kingdom that is more durable and indestructible than india-rubber.

Mr. C. F. Varley negatively acknowledges its superiority, but thinks we have arrived at such perfection in the matter of gutta-percha insulation as to leave nothing better to be desired, "it being quite sufficient to ensure good signalling through long lines of cable." But surely, with all deference to so eminent an electrician as Mr. Varley, we may be allowed to pronounce this a very lame and unsatisfactory conclusion to come to. Do we then arrive at such a state of perfection in anything as to have no desire for a still greater perfection? Assuming the truth of the statement, that the improvement made in the quality of gutta-percha to be as ten is to one what it was a few years back, still, the question is not to what degree of proficiency can we insulate a wire with this substance; but rather, how does it stand relatively as compared with the best india-rubber insulation? Is it better? or inferior? or what? The enthusiastic adherents of the former are bound to afford us proof of their assertions from actual experiment, and until they do they must be content to be met with incredulity on a matter which rests at present on bare assertion merely.

That india-rubber is much superior as an insulator to gutta-percha is further confirmed by the testing of the samples sent to the Indian Board as proposed cores for the Persian Gulf cable now making. In that case, as I have been informed on unimpeachable authority, the india-rubber samples exceeded those made of gutta-percha by fully 50 per cent. If I am wrong in this statement, now is the time for those who can to set me right, and so vindicate the course taken by the Indian Board and its engineers before the world; and until they do, they must rest under the stigma of having chosen a method of insulation which their own instituted experiments condemn.

Well, then, to what does all this lead as applied to the proposed Atlantic cable? Why, indubitably, that its core will be of gutta-percha also; this is inevitable; its engineer is an enthusiastic devotee of gutta-percha interests; and the incongruous elements that make up its consulting committee are, with one exception, the same. Its chairman, strangely enough, is G.P. to the backbone, so is its secretary; and, indeed, I may say, all in authority; and yet mark the results of inefficient insulation in long lines of submarine cables. Electricians tell us that induction is the greatest difficulty they have to contend with; and Mr. Varley described a most exquisite little instrument invented by Professor Thompson, in order to record the exceedingly faint signals transmitted through the old cable, and without which it would have been impossible that the cable could have spoken at all. Now, this is a fact to bear in mind; it speaks volumes. I would ask, how much of this loss by induction was due to the insulating material used, for it is scarcely fair to attribute it all to bad workmanship and ill-usage. Another fact to couple with the foregoing—and which is worthy of being written on the tablets of the memory of every shareholder of the Atlantic Cable—is, the Government committee recommended caoutchouc before all other materials, mainly on account of its *less inductive capacity*; nor does it require any one to be initiated into the mysteries of electrical science in order to understand that a high inductive capacity means so much waste electricity, and that the longer the line the feebler the current becomes until, if it be sufficiently long, a shadow of the original charge will hardly be left to announce that a message is in course of transmission. Mr. Varley, ever sanguine, estimates that he should be able to signal through the Atlantic cable made of a given quantity of copper, insulated to a specfic diameter with gutta-percha, at the rate of from 10 to 12 words per minute. Assuming that he could (an assumption, by the way, which few would feel disposed to make without a liberal discount), what is the inference? Manifestly, that a cable perfectly insulated with india-rubber could be worked through at the rate of from 15 to 18 words per minute, simply because the latter insulation is precisely 50 per cent better than the former.

But, whether Mr. Varley's calculations be reliable or not, this cable of all others is not the one that will admit of being constructed on suppositions and unsatisfactory data; especially with respect to its insulation. We have not to deal with a comparatively short cable of some hundred miles or so, but one unbroken line of upwards of 2,000 miles. In the former case, althongh desirable to secure the best, the question of loss by induction, owing to the inferior quality of the di-electric, is of comparatively trifling importance; whereas, on the other hand, the longer the length the more formidable the evil becomes in the ratio, as mathematically expressed by all electricians. Every existing cable, without an exception, is a practical illustration of the truth of the foregoing. We are justly proud of our success, and are not ashamed to own ourselves humiliated by so many repeated and inexcusable failures. But, important as our achievements have been, we cannot boast of aught but the most ordinary and make-shift insulation. The Malta and Alexandria cable, the longest in being, can only be signalled through at the rate of from four to five words per minute. The Toulon and Algiers, before it broke down, was but little better, and so of all the rest; and for this slow rate of signalling we have to thank the material used as the di-electric; in other words, gutta-percha. Besides, the higher the inductive capacity, and the consequent escape of electricity by this means, the more the insulation becomes impaired thereby, until finally it will result in the total collapse of the cable, providing that undesirable event be not hastened by other fundamental errors in the construction. In short, the whole question of success or non-success of submarine telegraphy turns upon the all important point of insulation, and is the main thing to be considered, although we should by no mears shut our eyes to other requisites—as lightness, improved methods of submersion, &c. We are not justified in prognosticating failure, if the predilections of the chairman, the engineer, and others foremost in the Atlantic Telegraph Company, are acted upon in the construction of this cable; but surely this company will think twice ere they risk another half million in a speculation which neglects to secure itself against anything and everything that in the remotest degree has the appearance of leading to non-success; but time will prove whether they are really as wise as we would feign hope; despite present appearances, they are.

PHILO.

ASSOCIATION FOR THE PREVENTION OF STEAM BOILER EXPLOSIONS, AND FOR EFFECTING ECONOMY IN THE RAISING AND USE OF STEAM.

THIS association has just issued its annual report. The report is so full of valuable information that we deem it advisable to give it to our readers almost extant. After some introductory observations on the character of the boilers examined, Mr. L. E. Fletcher, the chief engineer, says:—

Before entering upon the detailed consideration of the defects detected on the examinations, it may be stated, that a gradual improvement is found to be going on in the general character of the boilers under inspection, as well as in the arrangements of their fittings. The new constructions are marked with more simplicity and accessibility of parts and fittings, and can be more readily attended to by the engineer in charge, as well as more satisfactorily examined by the inspector, and entail much less anxiety in answering for their safety. Notwithstanding this general improvement, however, the defects ascertained this year are more numerous than those of last year; this may be accounted for by the increased number of "thorough" examinations previously referred to, which have revealed defects otherwise unknown; an additional illustration of their importance.

The defects discovered in boilers are mainly of two distinct classes—one relating to their construction, and the other to their condition.

Under the first head, namely, that of construction, 196 recommendations have been made, which are as follow:—

In 153 boilers the internal flue-tubes have been recommended to be strengthened by hooping.

In 18 boilers the shells have been recommended to be strengthened at the steam dome by stays of angle iron, &c.

In 9 boilers the shells have been recommended to be strengthened at the ends.

In 16 boilers the load on the safety-valves has been recommended to be reduced.

The following are those defects appertaining to the second head—namely, that of condition. Of these, 85, which are as follows, were considered dangerous:—fractures of plates and angle irons, 13; blistered plate, 1; furnaces out of shape, 12; corrosion, 37; defective safety-valves, 5; defective water-gauges, 9; defective feed apparatus, 1; defective blow-out apparatus, 7.

Others not actually dangerous, but still unsatisfactory, are as follows:—fracture, 60; blistered plates, 19; furnaces out of shape, 33; corrosion, 270; safety-valves irregularly loaded and otherwise out of order, 94; water-gauges out of order, 135; pressure-gauges out of order, 76; feed apparatus out of order, 35; blow-off apparatus out of order, 224; fusible plugs out of order, 49; also two instances of deficiency of water.

It may be added that many of the above defects were observed at visits made early in the year, and since that time many of them have been repaired.

To some of these defects more detailed reference may be made.

FRACTURE.

One of the most fruitful sources of fracture in boilers is the unequal expansion and contraction of their different parts, on account of the various temperatures, which are caused, in many cases, though not in all, by imperfect circulation of the water.

This has been kept in view so constantly in previous reports, that little more now is necessary than an enumeration of any additional facts, which have lately come under notice.

It may, therefore, briefly be stated that grooving still continues to manifest itself in double-flued boilers at the tube angle irons and end plates, more especially at the furnace mouth; and is more active in proportion as the end plates are rigidly stayed. In no class of boiler, however, is this action found to be so destructive as that in which the furnace tubes are brought so close together; that there is not room for the angle iron at either end of the flue to be carried completely round them; and is, therefore, supplemented by what is called a "saddle-plate," which, with its complement of the two partial angle iron hoops, forms a "spectacle-piece." These "saddle-pieces" are found to groove so deeply that in some cases the whole thickness of the plate becomes eaten through. There is no satisfactory cure for this but their entire removal, and the tapering down of the flue-tubes at the mouth, so as to increase the intermediate space.

Channelling at the transverse seams at the bottom of the shell of internally fired boilers, is still met with. It generally is discovered in the bottom external flue, on the outside of the plate immediately at the edge of the overlap, being deepest at the centre or "keel" line, and dying out in about 15 inches on each side, but very frequently in much less. In one instance, however, it was found on the internal surface of the plate, and to be situated as high as the side wall on which the boiler was set.

On the whole a gradual improvement, both with regard to channelling at the bottom seams, and grooving at the end plates and angle irons, is taking place in the boilers under inspection. This improvement is due, with regard to the former, to the more general adoption of means for heating the feed water, as well as to the boilers being now more frequently set, so that the heat from the furnace flues passes immediately under the bottom, and then lastly along the sides, by which means the circulation of the water is improved; while, with regard to the latter, the improvement is due to the fact of the end plates being now less rigidly stayed, and thus, as has been stated in previous reports, having room to "breathe."

Boilers with two furnaces running into a single oval flue, containing a number of vertical water tubes, have the advantage of a more rapid circulation of the water, which is decidedly calculated to prevent both transverse channelling at the ring seams and grooving at the angle irons. There are, however, but a small number of these boilers under inspection, in proportion to those of the double-flued class; but, as far as observation has been made, they certainly appear to compare favourably, on the above points, with their competitors. Water tubes have also been added in a few cases to ordinary double-flued boilers, being fixed behind the fire-bridge with a view to promote circulation, while, with the same object, a new boiler has lately been brought out, in which water pockets or mid-feathers at varying angles are fixed in the flue-tube, with a view of securing it against collapse, and at the same time promoting circulation of the water.

Other cases of fracture have occurred from fixing angle iron strengthening hoops to flues in an improper manner. This has been so fully gone into in the printed abstract of the monthly report for June last, and which was circulated amongst the members, that nothing need now be added beyond stating that several additional cases have since been met with of plates at the crowns of furnace tubes becoming burnt and cracked, when the thimbles or ferrules between the plates and angle iron hoops, explained in the above report, have been omitted.

Other cases, again, of fracture, have been caused by the flue-tubes and shell being bound together by a cross stay in the middle of their length, when, from the unequal expansion of the two, one has injured the other.

One case of fracture has been met with in an externally fired boiler, which occurred at one of the transverse seams of rivets, from the sudden cooling of the plates, by the too hasty introduction of a quantity of cold water immediately after blowing out, while very similar injury has arisen at the transverse seams over the furnaces in other externally fired boilers when in work, and, in addition, several of their plates have both bulged and blistered. Boilers externally heated by the flames passing off from iron furnaces have been found to be specially liable to start at the seams, and crack at the rivet holes, at the point where the flame impinges.

A boiler with two internal furnaces, as well as an external one beneath it, added with a view to promote circulation of the water, was found to bulge in the plate of the external shell over the fire, while the internal furnace tubes remained uninjured. It is thought that this boiler, from the fact of its combining within itself the two classes of firing, viz., internal and external, affords an apt opportunity of comparing the merits of the two systems, while the result just recorded is fully borne out, by a more extended observation of other boilers.

BLISTERED PLATES.

This subject has been somewhat anticipated under the previous heading, and it will now, therefore, be only necessary to point out, that the fact of plates, by good makers, being liable to blister unawares, and which previous examination evidently fails to detect, shows the importance of not hazarding an explosion upon their soundness. Thus the strength of no unassisted plate, exposed to the action of the fire, should be relied on; and, consequently, it becomes most desirable that furnaces should, in every instance, be stayed either by flanged seams, or with hoops of angle iron, T-iron, or other advantageous form.

FURNACES OUT OF SHAPE.

The general causes of shortness of water, from which overheating and injury to the furnace crowns ensue, are found to be as follows:—

1. The direct neglect by the engine-tenter of the feed apparatus, which is too obvious to need remark, and too glaringly careless to be otherwise than exceptional.
2. False indication of the glass water gauges.
3. Loss of water at night on account of leakage of the blow-out apparatus, sometimes from its being carelessly and imperfectly closed.
4. The lighting of fires by night watchmen, and others, without any water in the boiler.
5. Blowing the water out of the boiler with the fire still left in it.

An efficient low water safety valve, which would—on the sinking of the water below its proper level—relieve the pressure of the steam, would evidently save the furnaces under some of the above circumstances, though not under all.

It should be added, that some furnaces are out of shape from their first construction, being found on actual measurement to be as much so as one or two inches, merely from careless workmanship, which passes unobserved until detected on inspection. This inaccuracy considerably weakens the flues, especially when the major axis is horizontal, since the natural tendency of all furnace tubes is to collapse vertically.

CORROSION.

Corrosion is found to be going on in all boilers more or less, and it will be seen that the greatest number of dangerous defects in the preceding list are to be found under this head. A few instances may be given. In one case, a boiler set upon a mid-feather wall, 15 in. thick, had a channel eaten right along it about 8 in. wide, which ran down the centre of the seating, while the plate at the edges of the brickwork appeared quite sound, and the danger consequently passed for some time unsuspected. In a second instance, with a mid-feather 2 ft. wide, the plate was found to be eaten almost through from nearly one end of the boiler to the other; while in a third, where lime had been allowed to come in contact with the boiler at the mid-feather, the plate was completely pulverized, and could be carried away in handfuls. In a fourth case, a vertical tubular boiler had been placed close to a wall, one part being in actual contact. Damp in the brickwork set up corrosive action in the plate, which, being concealed by the position, went on undetected until the metal was completely eaten through, and a piece blown out by the pressure of the steam. The original plating of the boiler was thick, the pressure low, and the corrosive action local, only affecting a surface of about 12 in. square, so that the rent did not extend.

A fruitful source of corrosion is found in the leakage of blow-out pipes at their attachment to the shell, while in some cases the pipes themselves are fractured, and continue so for some time unawares, the leakage meanwhile playing on the bottom plate, from which corrosion necesarity ensues.

Examples of corrosion might be multiplied indefinitely; enough, however, has been said to show the importance of having all parts of the boiler accessible to examination, the flues sufficiently capacious, and the seatings as narrow as possible, and also of having the brickwork removed occasionally, at all events in places, so as to ascertain the condition of the plates, since to conclude that the parts concealed are in the same condition as those in view, has been found in practice to be fallacious.

The examples of corrosion, previously referred to, have all been external, and caused in every case by moisture, arising either from leakage or damp in the flue. Internal corrosion is not generally so dangerous, and arises from acidity in the water. Many members are now using carbonate of soda, and all those who do so, speak highly of it. Even the Manchester town's water is improved by the introduction of a slight quantity. This water is not found to be dangerously corrosive, but to speckle the plates over minute indentations, in some cases depositing small scales, like miniature flattened walnuts, about three-quarters of an inch in diameter, and one-eighth of an inch thick. These, on being severed from the plate, leave behind them shallow prints on its surface. One firm, having several 50-horse power boilers, and which are fed with Manchester town's water, uses half a pound of soda in each per diem, and finds this quantity sufficient to neutralize the acidity.

DEFECTIVE SAFETY VALVES.

Reckless or even careless overloading is now seldom if ever met with in the boilers under inspection, though some cases have come under notice of most defective arrangements in new boilers, the safety-valves being placed on the steam-pipes instead of directly on the shell, so that the communication between them was contingent upon the junction valve being open.

Many safety-valves are found improperly loaded, that is, insecurely so, and with loose irregular weights. Importance is attached to safety-valve levers being loaded, with but a single suitably-adjusted weight at their end.

The attachment of internal loading to dead-weight safety-valves has, in some cases, been found most insecure. This is a point, from the concealment of the weights and links within the boiler, which is likely to escape attention, though serious scalding would ensue in a confined boiler-house in case of the valves suddenly breaking loose. Of internally loaded dead-weight valves, those are the safest which are boxed-in and fitted with a hand-lifting lever, and a discharge pipe for the waste steam.

WATER GAUGES.

The recommendation previously given to fix duplicate water gauges to every boiler, and to have the passage in the necks as large as possible, can only be repeated, in the present instance, with the additional force which another year's inspection gives, and many furnace crowns would have been saved by the timely adoption of these simple precautions. The taps of glass water-gauges are almost always found to leak; this can be greatly remedied by having them fitted with nut-glands packed with a little cotton, while the grit, which so soon cuts away the plugs, would be much lessened by the adoption of surface blowing-out.

PRESSURE GAUGES.

All the pressure-gauges fixed to the boilers under inspection are checked by a standard indicator at each of the inspector's visits, provided that the boilers are fitted with the necessary tap. Thus the accuracy of most of the pressure-gauges passes constantly under review.

Generally, they are found to indicate too high a pressure. but, in some cases, as much as from ten to fifteen pounds too little; the first error leading to their being disregarded, and the second to actual excess.

The pressure-gauges under inspection are, with but a few exceptions, of four classes, namely, the natural mercurial column gauge; the mercurial differential gauge; the dial gauge; and the compressed air gauge.

The natural mercurial column gauge stands first upon the list for accuracy, as its simple and direct construction would indicate.

The differential mercurial gauge is of inverted syphon construction, the short leg being of larger diameter than the long one, and thus the mercury has less travel in the former than in the latter. The indications of pressure are read off from the short leg, which considerably reduces the length of the index scale of pounds, and those of the best class of this gauge are very legible. In one class of differential gauge, however, the mercury enters the glass indication tube, which becomes very much discoloured in consequence. and, in some cases, quite opaque; while, at the same time, the glass stands off so far from the index face, that it can only be read accurately when the eye is placed on a level with the upper surface of the mercurial column. In another class of this differential gauge the mercury does not enter the glass tube at all, but the pressure is indicated by a floating pointer, so that no discolouration of the glass takes place, and the gauge is always legible.

Dial gauges are very compact, and can be fixed directly in front of the boiler, just in sight; while those of the best class are very legible; care should be taken, however, not to fix them too near the boiler face, or else to put a piece of wood between the two so as to prevent their becoming heated, or otherwise their indications will be affected.

The compressed air gauge, in which a syphon column of mercury, as a piston, acts upon an air cushion, is found to be universally incorrect, and is quite unworthy of confidence.

In conclusion, while the natural mercurial column gauge must be allowed to stand the highest for abstract accuracy, yet the best description of the mercurial differential column gauge, as well as that of the dial gauge, are but slightly inferior to it practically, and are more easily read; while the dial stands pre-eminent for compactness, especially at high pressures, which becomes of importance in a long series of boilers, when each is fitted, as it is always desirable should be the case, with its own independent gauge.

DEFECTIVE BLOW-OUT APPARATUS.

It has already been stated, under the head of "Corrosion," how much injury is frequently done to the bottom plates of boilers by defective joints of the blow-out pipe; to remedy which, a short block should be rivetted to the boiler, and the pipe bolted to it instead of direct to the shell. These pipes, which are generally of elbow-shape, should not be bound by the brickwork, since the settlement of the boiler is apt to strain them, and cases have occurred in which they have been fractured in consequence. From this, in one instance, considerable corrosion ensued; and in another, not under the inspection of this association, in which the fracture was sudden and complete, scalding resulted to two or three persons.

Many blow-out taps are dangerous to use for want of suitable discharge pipes to carry off the waste water, and, in some boilers, the water spaces have been found to be completely choked with sediment, from neglect of the most simple precautions with regard to the use of the blow-out apparatus. This subject has been so constantly alluded to, that repetition would be tedious, though, perhaps, hardly unnecessary; it will, therefore, only be added that brass gland taps, recommended in previous reports, are still found to give satisfaction, and to be more certain in their action than either sluice or mushroom valves.

INCRUSTATION.

Some advance has been made during the past year in the prevention and removal of incrustation, although much yet remains to be done. It is too frequently concluded that incrustation and corrosion are not to be found in the same boiler, and that the plates beneath the scale are protected. Such, however, is by no means found to be universally the case, and frequently, on removing the scale, grooving, or other evidence of corrosion, is discovered on the surface of the plate beneath it. An inspection of a boiler, therefore, coated with incrustation, must always be unsatisfactory; not to mention the injury to the boiler itself, as well as the loss of heat that results from it.

The remedy adopted for this evil, in marine boilers, namely, "surface blowing-out," has been during the past year frequently brought before the attention of the members, and a drawing made of a simple un-patented arrangement, and placed at their disposal. A very considerable number have availed themselves of this, while, as many of the manufacturing engineers as have wished to do so, have furnished themselves with copies. In consequence of this, several of these scum pipes have been applied, the exact number is not known, but one firm among others may be mentioned, who have fixed one of these scum pipes to each of their nine boilers, and with the most satisfactory results.

This is not, however, the only description of scum pipe adopted. The subject of "surface blowing-out" has been taken up by others, and two varieties of apparatus patented, and somewhat generally introduced. It is thought that this diversity will rather prove of advantage than otherwise; and now that the general principal of "surface blowing-out" has been called attention to, the more individual ingenuity is directed to the details of the apparatus the better. A more minute reference to the construction of these scum pipes was made in the monthly abstract of October last; and now that these three classes have been in operation for some time, it is thought that the results of their working may shortly be made a matter of comparison, which, as soon as opportunity offers, will be communicated to the members.

The use of soda, for the prevention of incrustation, is found of considerable advantage, and increasingly adopted. It is, however, better introduced in small regular doses, than in large in-frequent charges. In many cases there might be fitted to the suction pipe of the feed pump a funnel mouth, by means of which the requisite charge could be introduced to the boiler without difficulty; its rate of ingress being regulated by a tap between it and the suction pipe. In some cases a separate feed pump has been adopted, fitted with a small cistern containing a day's supply, and this arrangement has been found to work most satisfactorily.

In conclusion, there are but few cases of incrustation which the use of soda, combined with regular blowing-out from the surface of the water, will not check.

CONSTRUCTION OF BOILERS.

The consideration of the previous defects, to which the boilers under inspection have been found to be liable, will, it is trusted, prove of assistance to members wishing to lay down new boilers, as well as to those whose business it is to construct them.

But it is thought, however, that a further service yet might be rendered. Such ample opportunity has been enjoyed of seeing when in work, as well as of examining while at rest, considerable numbers and varieties of boilers, and such full information has been collected with regard to them by the association, that it is thought if the best proportions were collated, and put together in the form somewhat of a specification, it would prove of more assistance still than observations and analyses of defects alone; not by any means a minute and technical specification, but a systematic explanation of such proportions as have been found to exist in those boilers, giving the best results, and needing the least repair. It was intended to include this in the present report, but, finding that it could not be given complete, it is reserved for insertion in the printed monthly reports which circulate amongst the members.

EXPLOSIONS.

It is to be regretted, that no means exist of ascertaining the whole number of steam-boiler explosions that occur throughout the United Kingdom, and there can be no doubt that many are never recorded at all. There are known, however, to have occurred during the last year, no less than 30 explosions, from which, at least, 87 persons have been killed, and 89 injured. Of the number of lives lost by some of the above, no account could be obtained; while, from one of them, as many as 29 persons were killed, and 12 injured; from a second 12 were killed, and 24 injured; and from a third, 6 were killed, and 8 injured.

The following list gives the description of boiler to which the explosions have occurred, with the number of each class, as well as of the persons killed and injured :—

Four haystack boilers—12 persons killed, 5 others injured.

Six plain cylindrical egg-ended boilers—6 persons killed, 6 others injured.

Three iron-works' boilers—47 persons killed, 44 others injured.

Three plain single-flued Cornish boilers—2 persons killed, 3 others injured.

Two plain double-flued Lancashire boilers—4 persons killed.

Three locomotive boilers, of tubular construction—4 persons killed, 5 others injured.

One agricultural boiler, of tubular portable construction—4 persons killed, 4 others injured.

One kitchen-range boiler—1 person killed.

Also seven other boilers, of the construction of which no reliable information could be obtained, and from the explosion of which, 7 persons were killed, and 22 others injured.

The haystack boilers, referred to above, were externally fired, and exploded through the failure of the part exposed to the action of the fire.

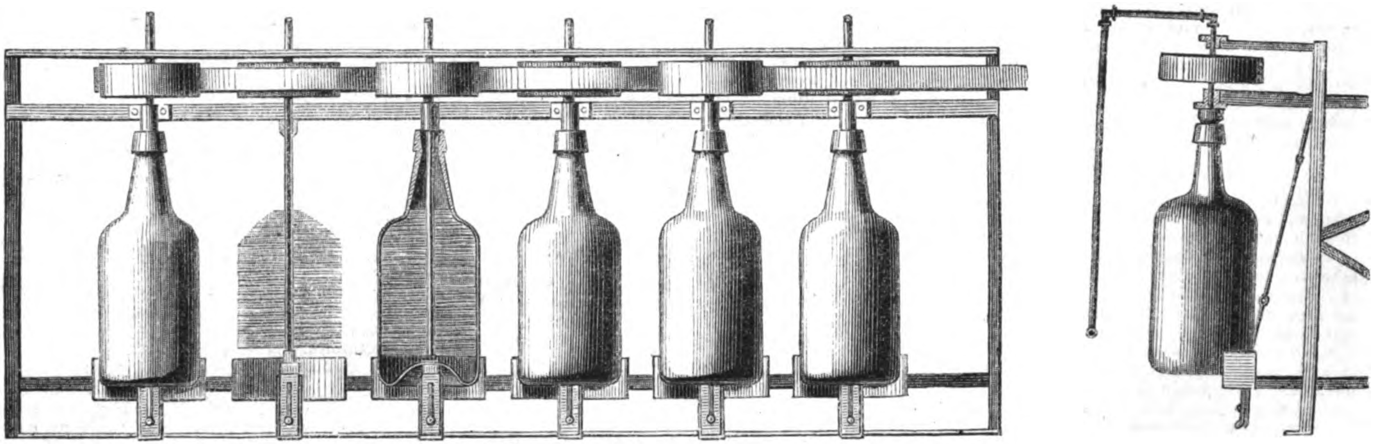
The plain egg-ended boilers, fired underneath, were found, in all cases, to have exploded from the rending of the transverse seams of rivets. One of these boilers exploded at the bottom of a coal mine, and in another case three boilers working side by side exploded simultaneously. Details of all these have already been reported in the monthly abstracts for February, March, and August, respectively, so that further particulars need not now be given.

The iron-works' boilers, were all heated by the flames passing off from the iron furnaces, which played not only upon the external shells of the boilers, but also through their internal flues.

The first of these was what is termed an "upright furnace" boiler, in which the flames, passing off from sometimes as many as four iron furnaces, impinge upon the exterior, and then pass into an interior descending flue. In this case the crown of the descending flue collapsed from original defective construction.

The second explosion occurred to a precisely similar boiler, but in this case the external shell gave way at the seams, upon which the flames from the iron furnaces impinged.

GILBY'S BOTTLE-WASHING APPARATUS.



Front Elevation.

Side Elevation.

The third boiler was a plain single-flued "Cornish" one, fired externally by the flames passing off from two iron furnaces, and internally by those passing off, through its flue tube, from another. The explosion was caused by collapse of the internal flue-tube, arising from defective construction, and might have been prevented had the flue been strengthened, either with flanged seams, or hoops of angle iron, T iron, or other suitable form.

Each of the three iron-works' boilers, was personally examined subsequently to its explosion, and full particulars were given in the March, April, and December monthly abstracts.

Of the three explosions which occurred to plain "Cornish" boilers, one was caused by collapse of the flue-tube, consequent upon shortness of water. This appears to have been caused by carelessness, the gauge-glass having been broken. The shell of the boiler was uninjured, and the only damage done was by the percussive action of the steam and water, in a direct line with the furnace tube.

Of the other two, no reliable information could be obtained; they are reported, however, to have failed at the front end plate.

Both the explosions, which occurred to boilers of the plain double-flued "Lancashire" class, were caused by external corrosion of the plates, which were so eaten away in one case as to be reduced in thickness to the sixteenth of an inch, and in the other to that of a sheet of paper.

One of these boilers was under the inspection of this association, but the opportunity had not been afforded to its inspectors of making the regular annual "thorough" examinations, the importance of which has been so repeatedly called attention to in the reports. This subject was gone so fully into in the monthly report for July last, shortly after the explosion happened, that it is needless to repeat the details here; while the particulars of the other, which also was personally examined, will be found in the monthly report for last December.

The locomotive boilers, in every case, exploded from thinning of the plates, caused by internal corrosion, it being a general practice in the management of locomotives only to make a thorough internal examination of the shells of the boilers, when the flue-tubes are renewed. This, in some cases, has allowed an interval of as much as seven years to elapse between one examination and another, during which time the boiler has been working in a state of complete uncertainty, the actual condition of the plates being unknown. The use of the hydraulic pressure is objected to by several locomotive engineers, though not by all; it is a point which has provoked a good deal of discussion, and is too lengthy to enter upon, on the present occasion. It may, however, be stated, in brief, that no case has been met with, in the experience of the association, in which injury has resulted from the judicious application of this test, and also that no opportunity will be lost of contributing any information on the subject that the experience of the association may afford. It is one of considerable interest, and affects the safety of the whole travelling public.

The kitchen-range boiler exploded from accumulated pressure, the taps of both the inlet and outlet pipes being closed at the same time, in consequence of which there was no escape for the steam, there being no safety-valve.

Of the cause of the explosion of the agricultural portable boiler, as well as of those which occurred to the remaining seven at the bottom of the list, no reliable information has been received, while the distance at which nearly all of them happened precluded personal examination.

The causes of the above explosions may be systematised as follows:—

Of 30 explosions, which happened during the year 1862, 11 occurred to externally fired boilers from failure of the plates exposed to the action of the fire; 3 resulted from internal corrosion, and 3 from external; in addition to which, 4 were due to improper original construction, one to shortness of water, and another to accumulated pressure through want of a safety-valve; while 7 occurred at a distance which precluded a personal investigation of their causes, at the same time that no reliable information could be obtained with regard to them.

It may be added that the explosion, which occurred to a double-flued "Lancashire" boiler, and from which one life was lost, is the third fatal explosion which has happened to any of the boilers under the inspection of this association, since its establishment eight years ago; to which should be added three cases of collapse of furnace flues, not attended with any serious consequences, and which arose in two instances, if not in all three, from shortness of water. During this period 712 dangerous defects have been pointed out in the boilers under inspection, from which serious injury might have arisen in each case; while, upon limited inquiry only, it has been found that no less than 213 explosions have occurred in that time to boilers not under the inspection of this association, which have been attended with the loss of 472 lives, in addition to serious injury to 512 persons, and considerable damage to property.

ENGINES.

The depressed state of trade during the past year has so disorganised the ordinary working of most of the mills, that it has been found impossible to draw up a reliable comparative table of the economic duty of the engines. Indicator diagrams alone, however, from most of the engines under inspection, never afford the necessary data for correct comparison, since so much steam is drawn off for purposes other than that of motive power. It becomes, therefore, highly desirable that water metres should be fixed to each series of boilers, so as to ascertain the amount of water evaporated. This would enable a comparison to be made of the evaporative power of different boilers, and of the value of different coals, while at the same time the diagrams would afford an indication of the working of the engines.

Two pair of engines, built during the past year, have had their cylinders fitted with steam jackets; and a superheating apparatus, for raising the temperature of the steam in its passage between the boiler and engine, has been introduced in two or three instances. The object of both these arrangements is economy of fuel, and it is intended, as soon as possible, to investigate the results obtained, in order to communicate them to the members.

A "surface-condenser" is being constructed for a pair of beam-engines, and will, it is expected, be put to work early this year. "Surface-condensation" is the most radical preventative of incrustion, since, whatever the character of the condensing steam may be, this condensor returns to the boiler distilled water; the same quantity, with the exception of a small amount of waste, being used again and again. There are many cases in this district where this will prove valuable; and the results of the application in the present instance will be a matter of considerable interest to many of the steam users of the district.

CONCLUSION.

A very brief recapitulation may be allowed, in conclusion, of some of the points attained during the past year.

"Surface blowing-out" has made considerable progress. "Steam-jackets," so long discarded in this district, have been revived, and "superheating" introduced, while a "surface-condenser" is about to be applied.

Although these arrangements are not in general use here, they have been fully tested elsewhere, and it is thought that much may be gained by importing, as it were, into this district, the engineering experience of others. For instance, the "steam-jacket" has, in combination with the use of highly-expanded steam, been the principal element in the attainment of that economy for which the Cornish engine has for so long since been notorious, while "surface blowing-out" and "surface-condensation," as well as "superheating," are due to marine engineering practice, which has developed a higher economic result than that generally obtained in this district.

Although it is true that all really sound and beneficial mechanical arrangements, practised in one district, will, in time, surely find their way into and secure for themselves adoption in others; yet it is thought that this association can do much to hasten this process—too frequently a tardy one—by circulating, upon these points, information amongst its members; and to assist in doing which, as far as it lies in my power, will always be regarded by me, not only as a duty, but a source of satisfaction and pleasure.

It is trusted that, during the present year, the mechanical arrangements just referred to will be fully tested, and general confidence and adoption secured in this district, for such of them as prove worthy of it; so that the desire expressed at the conclusion of the last annual report may be realized, namely—"That no year may be allowed to pass, without a decided mark of progress being clearly stamped upon the engineering practice of the district, by this association." For the accomplishment of this, however, the co-operation of the members is absolutely necessary. Comparative returns of the working of engines cannot be made, unless the members have their engines indicated; neither can the consumption be calculated, without accurate returns; nor the evaporative power of the boilers arrived at without the application of water meters.

GILBY'S BOTTLE-WASHING APPARATUS.

AN ingenious arrangement of apparatus for washing bottles, and which we illustrate in the annexed engravings, has just been patented by Mr. A. Gilby, of Oxford-street. The arrangement consists of fitting a series of brushes upon a suitable frame, each fixed upon a hollow spindle, which, with the brush, revolves in the inside of a bottle to be cleansed, as clearly indicated. Through these hollow spindles, and by means of a pipe in connection with a suitable tank, a supply of water is carried into the inside of each bottle, an by the action of the brushes revolving is used to cleanse the inside of it. The bottle is placed slightly inclined from the horizontal plane, its mouth falling into a hollow metal boss, through and upon which the hollow spindle is mounted, and, with the brush surrounding it, is passed into the interior of the bottle. The bottom end of the bottle is laid upon a sliding seat, so as to regulate its position. The slide is held to its place by means of a spring, so that the bottle is steadied and held in its proper position during the operation. The hollow spindles, with the brushes, are caused to revolve by means of rollers, or pullies and straps, or by any other well-known motion. When complete, the frame upon which the whole is mounted is arranged so as to form a trough to receive the dirty water as it comes from the bottles after and during the operation.

PROCEEDINGS OF THE INSTITUTION OF MECHANICAL ENGINEERS.

On the Manufacture of Hemp and Wire Rope.

By Mr. Charles P. B. Shelley.

(Continued from page 121.)

The rope laying machine for laying the hemp strands into rope is shown in Fig 5. The three spools A, filled with strand from the registered machine last described, are carried in the vertical spool frames B, which are centered at top and bottom in the main frame C of the machine. The entire machine revolves round the fixed centre shaft, and is driven by the small bevel pinion D gearing into the wheel E at the bottom of the main frame C. The spool frames B are made to rotate on their axes during the revolution of the machine by means of the pinions F on the spool frames and the counter wheels G gearing into the dead wheel H, which remains stationary, being fixed on the centre shaft of the machine. If the pinions F were of exactly the same diameter as the dead wheel H, the spool frames would make exactly one rotation on their axes for each revolution of the machine, and the spools would be preserved constantly parallel to themselves while the machine revolved, so that the strands would be laid into the rope without any additional twist in the individual strands. But in order to ensure the yarns in each strand being thoroughly closed upon one another, a slight additional twist or "forehard" is given to each strand in the act of laying it into the rope, by making the spool frames perform rather more than one rotation on their axes for each revolution of the machine, since the twist of the yarns in each strand is in the contrary direction to the twist of the strands in the rope. The pinions F on the spool frames are, therefore, made of smaller diameter than the dead wheel H, in the proportion of 13 to 14. From the spools A the strands are drawn off round the stretching pulleys I I, as shown dotted in Fig 6, which are driven by bevel gearing and pinions J from a dead wheel fixed on the centre shaft at the top of the machine, with counter wheels and pinions K similar to those at the bottom. The strand is pressed tight into the groove of the upper stretching pulley I by the small tightening pulley L, Fig. 6 and 7. The spool A is retarded from unwinding too fast by a friction break, which is adjusted to any degree of tightness required. The strands pass up through the hollow bearings at the top of the spool frames B and through the pinions K, and are curved over the oblique guiding rollers M, which are fixed at varying inclinations, in order to prevent the strands from slipping off. The three strands then unite at the centre and are laid together into the rope by the revolution of the machine, each strand being laid into the rope with the required amount of "forehard" by the simultaneous rotation of its own spool frame in the contrary direction to the machine. The newly made rope is carried upwards to another machine, where it is stretched over and under three pulleys driven by steam power; and as it passes from the last pulley it is compressed by a roller kept against the rope by a strong steel spring. It is afterwards finally coiled away in a warehouse.

There were three rope-laying machines at Devonport Dockyard, and they were calculated to make about 3,000 tons of cordage per year of 313 days. Of this amount the largest machine would make 2,000 tons of cables and hawsers of large size, the cables ranging from 14 to 24 in. girth and the hawsers from 7½ to 12½ in. girth; the second machine of intermediate size would make 700 tons of cable-laid ropes from 8 to 16 in. girth, and hawsers from 5½ to 7½ in. girth; and the smallest machine would make 300 tons of cablets from 5½ to 7½ in. girth, and shroud-laid ropes from 3½ to 5 in. girth. The average cost, including all charges of the establishment, engine power, repairs of machinery, &c., is said not to have exceeded 17s. 4d. per ton of cordage made, when the whole machinery was employed to the fullest extent of its capability; the cost by hand at the same period being stated to be 24s. per ton.

The strength of hemp rope varies considerably, and depends principally on the quality of the hemp from which it is made, the number of yarns composing the strands, and the manner in which the ropes are laid. The average strength of each yarn in hawser-laid ropes is found to be greatest with the smaller sizes of ropes. Shroud-laid rope made with four strands is about one-fifth weaker than hawser-laid made with three strands, on account of the additional twist or "hard" which is given to the shroud-laid; and cable-laid rope is about one-third weaker than hawser-laid rope. The strength of these three different lays is, therefore, in the proportion of cable-laid 10, shroud-laid 12, and hawser-laid 15. The relative breaking weights of ropes made from the three most ordinarily used materials are stated to be as follows:—taking the breaking weight of St. Petersburg hemp rope at 100, that of Italian hemp rope is 107, and that of Manilla rope 73. Tarred rope is weaker than untarred, other circumstances being the same; for the quality of the tar seriously affects the strength of the rope. Hence the strongest ropes are hawser-laid or three-strand ropes made of untarred Italian or Russian hemp.

Wire rope.—The second branch of the subject of the present paper is the manufacture of iron wire rope, which, although at first made by hand, is now made exclusively by machinery.

Wire ropes were used as early as 39 years ago for the supporting cables of a suspension bridge at Geneva; and also for the Freiburg suspension bridge of 807 ft. clear span, erected 27 years ago. The wire ropes in the latter case, shown in the engravings, are constructed of 20 bundles of strands of straight iron wire 0·125 in. diameter, stretched parallel, forming a rope 5½ in. diameter, and bound round with wire at 2 ft. intervals.

The first form of wire rope regularly manufactured was made about 27 years ago, and was known as "selvagee." It consisted of a number of hard or unannealed wires, of about 12 to 16 wire-gauge or 0·110 to 0·065 in. diameter, which were stretched parallel and bound together by a fine wire of about 20 wire-gauge or 0·036 in. diameter, wound spirally around; after which, a "parcelling" of woollen list was also wound round in the contrary direction, with the edges lapped so as to cover the wires entirely; the rope was completed by a service of tarred yarn wound on in the contrary direction to the list. The method of making the rope was simply to warp or stretch the wires at a uniform tension over two hooks set at the distance of the length of rope required to be made, passing the wires backwards and forwards over the hooks as many times as was necessary to make up the size required. A solution of india-rubber boiled down in linseed, with a mixture of resin and tar, was rubbed carefully into the body of the rope, previous to binding up; and after the binding wire had been wound on, the solution was again applied to the exterior wires to prevent oxidation, the process of galvanizing being unknown or not practised at that time. The "parcelling" of list was also saturated with the solution, the yarn being tarred as usual. The binding and parcelling were always done by hand, before the rope was taken off the hooks; but the service of yarn was usually laid on by a machine for that purpose, though occasionally also by hand. The method of attaching the fittings, such as shackles, thimbles, and dead eyes, was either by forming an eye during the process of warping to receive them, or by inserting the end of the rope stripped to the wires into a conical socket attached to the shackle, and turning back the ends of the wires so as to prevent the rope being drawn out. But more generally the fittings were "turned in;" that is, the end of the rope was doubled round and "seized" or bound to the standing part. It will be seen that it was very difficult to splice this form of rope, owing to the absence of twist or "lay."

Ropes thus made were exceedingly rigid and non-elastic, but possessed greater strength than any other construction; in fact, the entire strength of the wire was preserved. The "parcelling" and "service" added to the size, but not at all to the strength, being intended only for protecting the wires. The want of elasticity and pliability, together with the difficulty of fitting, and the constant wear of the "service" of yarn, acted somewhat prejudicially against the introduction of this first form of wire rope on an extensive scale; yet it was used in the royal navy and mercantile marine, and also for suspension and tension bridges: for the latter purpose it is still used, especially in California, where a large number of wire rope suspension bridges are now being erected to replace those destroyed by the late floods.

The machinery for making these "selvagee" ropes consisted simply of the two hooks over which the wire was warped, which were attached to moveable posts set at the required distance asunder. The "serving" machine was a long wood trough extending nearly the entire length of the rope ground, having a revolving shaft at each end with a hook at its extremity, and carrying a fast and loose pulley, over which a driving band passed. The two serving hooks were driven at the same speed of about 400 revolutions per minute: and the shifting forks of the driving bands were connected by a cord extending throughout the length of the ground, so that the workman could stop or start the machine at any part. An ordinary serving mallet was employed for laying on the yarn, and was guided by the workman who also regulated the tension, the yarn being supplied from reels hung overhead.

The next description of wire rope was known as "formed" rope, and was introduced about 25 years ago. It consisted of a number of soft or annealed wires, usually about 14 wire-gauge or 0·085 inch diameter, "formed" or twisted into a strand, but with little or no regard to regularity: and four of these strands were "laid" into a rope, though this number was not always the same. The number of wires was varied according to the size of rope required, and occasionally the size of wire was altered to suit circumstances. These ropes closely resembled ordinary hemp ropes in appearance. The twist caused by "forming" the strands remained in the wire as a permanent set, and the strands were "laid" together with an extra amount of twist or "forehard" in each strand, which was necessary to keep the rope together. Little or no injury was done to the wire by this process, owing to its being annealed, and also from the length of the twist of the wires in each strand, which was usually about 12 inches pitch; but it would be almost impossible to use hard wire in this manner.

The "formed" wire ropes possessed great pliability and some amount of elasticity; they were readily spliced and fitted, like ordinary ropes, and though not so strong as the "selvagee" wire ropes, they possessed many advantages and were more easily introduced. Their adoption for rigging, incline, and traction ropes, became extensive; and this construction was the first wire rope used on the Blackwall Railway. The small size and soft nature of the wire used offered little resistance to exterior friction, and when employed as incline or running ropes they soon flattened and wore out. The irregularity with which the wires were "formed" or twisted into strands, frequently crossing and recrossing one another, and the great difference in the length of the wires as well as the short "lay" of

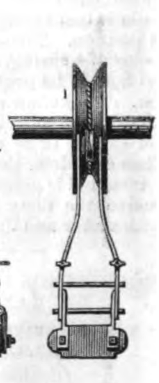
FIG. 7.



Tightening Pulley.

the ropes, amounting to only 4½ in. pitch, materially assisted to destroy them. Even when used simply as standing rigging, the wires frequently broke, and the broken ends stuck outwards to the danger of the sailors handling the rigging; and to prevent accidents they were served with yarn, like the "selvagee" rope, after having been "wormed;" that is, having a yarn laid in between each strand so as to alter the shape to a round form.

The "formed" wire ropes were originally made on the rope ground by the forming machine usually employed in hemp rope making. The wires were wound on bobbins placed in racks, just like the hemp yarns, and were led through the perforated register plate, called the "minor" plate, thence through the taper steel nipper or compressing tube, and were attached to the forming machine, which drew out the wires and twisted them together as it travelled backwards towards the other end of the ground. Having arrived there the machine was stopped, and the length of strand thus made was wound upon a large reel, ready to be placed in the laying machine; the use of the reel also enabled a longer length of strand to be made than one length of the ground. For laying the strands into rope, the required number of reels of strand, generally four, were placed in frames mounted on horizontal bearings and geared together. The strands were stretched along the rope ground, being supported and separated on trestles placed at intervals; and were brought together over a "laying top" at the other end of the ground, and attached to a revolving hook. Motion was given to the machine at one end with the four strand reels, and to the hook at the other end in the opposite direction, by means of a "fly-rope" or endless driving rope, passing over whelp wheels attached to the machine and the hook; the laying top was carried by a workman, who thus regulated the amount of lay or twist. Afterwards the laying top was mounted on a carriage which travelled on rails, and was drawn forwards by another endless rope, called the "ground" rope, which was worked by the machine. This arrangement had the effect of more effectually regulating the lay. "Formed" wire rope is now made in the ordinary vertical machine, which is supplied with extra frames for carrying a large number of bobbins; but for forming the strands the bobbin frames are fixed to the frame of the machine, and not revolving in it, and the wires are brought together through a perforated plate containing the required number of holes.

"Formed" wire ropes were at first well saturated with the solution before described; but afterwards galvanised wire was used for making them. The Admiralty still continue to use the "formed" rope entirely, though little is now used elsewhere. "Formed" ropes made of copper wire were used largely in the navy as lightning conductors, the size of the wire being about No. 20 wire-gauge or 0·036 in. diameter, and the rope was made of four strands laid round a small copper wire core. Smaller ropes composed of iron and copper wire were also used as sash lines, &c.

In another kind of wire rope, which was sometimes made on the machinery above described for the manufacture of "formed" rope, the strands were composed of hard wires, usually not exceeding six in number, laid around a core of hemp or wire; and these strands were again laid around a hemp core into a rope. But the objections caused by the rigidity of these ropes prevented any but small sizes being used for some years. Ultimately, however, these objections were overcome, and this construction has now almost entirely superseded the "formed" rope.

The first flat wire ropes, made twenty-six years ago, were composed of from eight to twelve "formed" strands, with the twist alternately right and left handed, made of a number of fine wires usually about 18 or 20 wire-gauge or 0·050 to 0·036 in. diameter. These strands were placed in the position of the warp, in a loom of the ordinary form, but greater strength, and were

woven together with a shoot of strong yarn. Very little twist was put into the strands, as the yarn when woven in kept them in form. These ropes were by no means durable, as the yarn soon wore out, especially at the edges; and their application was very limited.

Flat wire ropes were next made, about 25 years ago, of four or six "formed" ropes, each made of four strands "laid" very long, and alternately right and left handed; these were stretched together side by side and sewn through with six wires of No. 14 or 16 wire-gauge from side to side in a zigzag direction, as shown. This was accomplished by carefully inserting a needle of dagger shape between the strands of the ropes, and so making a passage for the wires, which were carefully laid side by side. The round ropes thus bound together resembled the ordinary flat rope in appearance. The process was tedious, on account of the care necessary to avoid penetrating the strands with the needle, which would do great injury to the rope. It was also important that the amount of "lay" or twist in all the ropes composing the flat rope should be exactly the same, otherwise the stretching could not be regular, and some of the strands were liable to be cut when the rope was set to work. With the machinery previously described perfect regularity could not be attained in this respect, and an unsatisfactory result was the consequence.

The next and last construction of wire rope, introduced about 24 years ago, is known as "laid" rope, in which the strands were made of a few wires, seldom exceeding six, "laid" around a core of hemp or wire, the wires of the strand being entirely free from twist, each wire being simply "laid" in a spiral form without any twist in the wire itself. Six of these strands were again "laid" without "forehard" or additional twist into a rope, around a core generally of hemp. The size of wire usually varied with the size of the rope, as the total number of wires, 36, was seldom varied. The wire was hard or unannealed; and by the system adopted in making a uniform length was obtained with entire absence of twist. By this means, the full strength of the wire was retained, and, consequently, the rope produced was much stronger for the same weight. An increase in size is, however, caused by the introduction of the hemp cores, which amount to one-seventh of the entire bulk in the case of ropes with six strands of six wires each, the construction now usually adopted.

These "laid" wire ropes, though not so pliable or strong as "formed" ropes, possess many advantages, especially when employed as incline ropes, the hardness and increased size of the wire giving greatly increased durability; and as the prejudice against wire ropes had been partially removed by the introduction of the "formed" ropes, the present "laid" ropes soon began to be extensively used; and within the last few years, since the expiration of many patents formerly existing, the manufacture has increased to a remarkable extent. Wire strand has lately come into extensive use for fencing, very large quantities being exported for that purpose for the Indian railways.

Flat wire ropes also are now made with strands composed of hard wires "laid" together, instead of "formed" as previously, these strands being again "laid" into ropes without any "forehard" or additional twist, and the ropes are then stitched together as previously described. Lately, instead of several wires laid side by side being used for stitching, three or four strands have been substituted, each strand containing three wires laid together; the advantage of which is, that though several of the single wires may be worn through, the strand still holds the rope together: yet in neatness of appearance the single wires have the preference.

The machinery used in the manufacture of "laid" strands and ropes originally consisted of the ordinary machinery used on rope grounds for laying or closing hemp ropes, the machines at each end of the factory being speeded alike, as previously described.

The next form of machine adopted had simply one hook, mounted in bearings on a fixed frame, and driven by hand or power, to which all the wires composing the strands were attached; these were stretched along the ground, supported at intervals on trestles, till they reached the other end, where they were hooked on to swivels or "lopers." Attached to the lopers were cords passing over pulleys, and having weights suspended from them so as to regulate the tension of each wire and also allow for the shrinkage of the rope in the process of making. When the hook was set in motion, the twist in each wire traversed the entire length of the wire, and escaped at the end by means of the "loper" or swivel. A perforated plate or "laying-top" was used, carried by a workman along the ground, regulating the amount of "lay" or twist.

The next machine used, shown in Fig. 8, was a modification of Huddart's hemp rope laying machine, previously described and shown in Fig. 5. In these machines the operation went on continuously until the required length of strand or rope was made, giving rise to the name of "endless" machines; they were also called "vertical" machines, because the main frame carrying the spools revolves on a vertical axis. The first modification of this machine for making wire ropes consisted in altering the gearing for working the spool frames B, so that no additional twist or "forehard" was put in the wires as in the strands of hemp ropes, the pinions on the spool frames being now made of exactly the same diameter as the central dead wheel, causing the spool frames to make exactly one rotation on their axes for each revolution of the machine. Machines of this description were also made to work on a horizontal axis instead of a vertical one; and a balance weight was sometimes attached to each spool frame in the horizontal machines, which by its gravity prevented the spool from twisting the wire and rendered gearing unnecessary for the purpose; but the speed of these machines was limited in consequence.

The next form of machine was that known as a "compound" machine, for producing the entire rope finished at one operation; and may be described as consisting of six stranding machines, like that last described, all mounted on one large frame and revolving horizontally, the necessary motion being given to the machinery to lay the wires into strands, and then the strands into rope, without producing any twist in the individual wires. This machine, though a mechanical success, was a commercial failure, and was soon abandoned for the simpler and cheaper plan of first making the strands and then laying them into ropes on separate machines.

Next some modification was made in the vertical machines, shown in Fig. 8, in the means of preventing twist of the wires during the laying, by employing a centre crank or eccentric and four outer cranks on the spool frames B, as shown in Fig. 8; and also by substituting chain wheels and pitch chain. Machines were constructed with 36 spools on the revolving frame, connected by cranks to the centre crank; and ropes were thus made with that or any smaller number of untwisted wires in each strand; but this description of rope was rarely used.

In all the vertical and horizontal endless machines that have now been described, all the spools were mounted in one set on a single large revolving table, thus revolving all in one plane; and during the process of laying, the whole weight of the material had to be carried round a circular track varying with the size of the machine from 10 to 40 ft., one revolution being necessary for every lay put into the strand or rope, the lay varying from 1 in. to 18 in. or more, in pitch, according to the size of rope. Machines of this construction were therefore necessarily limited in their speed. Lately, however, machines have been constructed with the spools arranged in two sets of three each, on two tables one below or behind the other, the spools thus revolving in two planes; whereby a somewhat increased speed was attained, as the diameter of the revolving tables was reduced. Yet still the spool frames had to be carried round the common centre, and caused to rotate on their own centres once for every lay.

The method of joining the lengths of wires was, in the first instance, by twisting the ends together; afterwards, in the manufacture of "laid" strands, by "tucking," that is, cutting out the hemp core about 12 in. from the end of the wire that has run out, and inserting in its place the end of the new length of wire; the rest of the wires are then "laid" up on the new wire as a core for a length of 6 in., when the new wire is brought out into its right place, and the remaining 6 in. of the old wire passed in as the core, on which the laying is again continued till the end of the wire is reached; the proper hemp core is then replaced, and the process of laying resumed as before. Some manufacturers prefer to braze or weld the ends of the wires together for joining the lengths; wire as small as No. 16 wire gauge or 0·065 in diameter being welded by experienced workmen by means of a common portable forge.

An improved construction of wire rope machine has subsequently been introduced by Mr. A. Smith, of London, in which the bobbin frames and bobbins are placed one behind another all in the axis of the revolving frame, and remain stationary in that position, while the frame alone is made to revolve. By this machine a greatly increased speed is attained, and it is considered that better work is produced. The rate of production is also much increased; as much as 10,000 yards of strand having been made per day of ten hours, instead of only 2,500 yards, the usual amount made by the ordinary form of machine.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

At the ordinary meeting, Feb. 10, 1863 (E. W. Binney, F.R.S., F.G.S., in the chair), Mr. Dyer read a paper entitled "Notes on the Introduction of Steam Navigation."

Mr. Dyer stated that this subject, being of great importance, had engaged many able pens in tracing the origin of the several inventions and experiments that preceded the final triumph of steam power over that of wind for navigating ships; each writer claiming the honour of priority for his own country. It may be useful to state the order in which and the parties by whom the principal attempts were made to realise that object. Several letters lately appeared in the *Times*, and were thence transferred to the pages of the *Engineer*, giving a graphic account of the "first steamer in English waters," the "'Margery,' built at Dumbarton, by the late William Denny, for William Anderson, of Glasgow, and passed through the canal to the Forth, and thence to the Thames, where she arrived on the 23rd of January, 1815." On the authority of Mr. Anderson, then, this date is fixed when the first steam-boat was seen on English waters. The first steam-boat, the "Claremont," was started as a regular packet on the Hudson River in the spring of 1807; so that the first steamer seen on the American waters was fifty-five years ago, a lapse of time that should now insure a calm view of the steps that led to this first actual success in steam navigation. It will be shown that, by a long course of persevering labour, the honours of that success must be conceded to Robert Fulton, by whom it was achieved.

Whilst admitting the merits of other ingenious men long engaged in the same pursuit, it is clearly proved that, either from good fortune, or by the exercise of superior judgment and skill the race was won by eight years' priority of steam navigation, by Fulton, on the Hudson river.

In 1793, Mr. Fulton sent his plan for a steam-boat to Lord Stanhope, who approved of, and thanked him for the communication. Shortly after, Fulton went to Paris, and made experiments on the French waters, with the chain floats, the duck's-foot paddles, the screw or smoke-jack propellers, and with paddle wheels, to which latter he gave the preference, and constructed a boat with them in 1803, which was the model adopted in building the "Claremont," in 1806.

Mr. Dyer had sailed in the "Claremont," and remembers the sensation created by her appearance, and the high admiration bestowed on the author of so great an enterprise. That sensation in 1807 was precisely the same as the "Margery" created among the vessels on the Thames in 1815.

All attempts at steam navigation were fruitless before the invention of Mr. Watt's steam-engine, his engine being the first that could be usefully applied to rotative machines on land, and therefore for propelling ships. The principal claims put forth by other inventors of steam-boats are the following:—

In France, the Marquis de Jauffroy constructed a steam-boat at Lyons, in 1782, "with paddle wheels," but that this boat did not succeed is obvious, because she was not heard of until 1816, when the first Fulton boat was started to run on the Seine.

In 1783, Daniel Bernoulli proposed a plan which consisted of forcing water through a tube, out at the stern of the boat. This scheme has been tried many times since, but fails on account of the defective principle of applying the force. Endless chains, with float propellers, have been many times tried, and have failed on the same ground.

In 1795, Lord Stanhope made experiments with a boat on the Thames, using the reciprocating or "duck's-foot" paddles, which also failed, from the loss of time and power by the return stroke.

In 178[illegible], James Rumsey, of Virginia, tried a boat on the Potomac, and afterwards in London, both without success; and about the same time Mr. Fitch, of Philadelphia, tried one with paddle wheels, on the Delaware, but this boat also did not succeed and was given up as a failure. J. C. Stephens, of New York, made experiments in 180[illegible], with a "boat 25 ft. long and 5 ft. wide," which of course did no good, and was [illegible] a failure, though again brought to notice as preceding Mr. Fulton's

In 1788 and 1789, William Symington, in conjunction with Patrick Millar and James Taylor, made experiments with their patents for navigating by steam, and in 1802 commenced running a boat on the canal at Glasgow which made three miles an hour, but after many changes of her propellers, and trials, the scheme was given up, and no more was heard of the steam-boat of Mr. Symington until long after those of Fulton were widely spread over the American waters.

In 1816, the Marquis de Jauffroy complained that the Fulton steam-boat on the Seine had taken the "paddle-wheels" invented by him and used at Lyons thirty-four years before, but also abandoned by him. To this charge Mons. Royou replied in the *Journal des Debats*, thus:—"It is not concerning an invention, but the means of applying a power already known. Fulton never pretended to be an inventor in regard to steam-boats in any other sense. The application of steam to navigation had been thought of by all artists, but the means of applying it were wanting, and Fulton furnished them."

The first ocean steamer was the "Fulton," of 327 tons, built in 1813, and the first steamer for harbour defence was built under Fulton's direction, 2,740 tons, launched in 1814. This became the model ship for the iron clad batteries and rams, since constructed with many changes. It will be seen by the drawings of Fulton's plans, that he had tried the several other kinds of propellers—the chain float, duck's-foot, and the screw fan—before adopting the paddle wheel, for though the screw was good in principle, it was many years before it could be constructed to act efficiently. The "James Watt" was the first boat with the screw running between London and Havre, about ten years after the advent of the "Margery."

In 1811 I endeavoured to introduce steam navigation into England, but I found a strong conviction that it would not answer in this country, our most eminent engineers saying, "We don't doubt the success of steam-boats in the wide rivers and harbours of America, but in our comparatively small rivers and crowded harbours they will never answer." Even such scientific engineers as the late John Rennie, sen., and Peter Ewart, a vice-president of this society, both advised me to relinquish the attempt to introduce steam-boats, as sure to prove a waste of time and money to no purpose. However, when conviction came over the public mind that steam navigation would answer here—but not until after more than 5,000 tons of steam-boats had been launched on the Hudson in 1816, did it so come—then began the spread of steam navigation, since extended with such marvellous rapidity and perfection as to atone for the sluggish beginning. Since nations are indebted to the genius of Watt for success in using steam power, to that of Fulton for its successful application to navigation, to Stephenson for the like success on railways, the meed of praise due to each of their names should be cheerfully awarded by all who are so largely benefited by the result of their labours. In doing this we should bear in mind, that inventions do not spring into existence perfect from their birth, like Pallas from the brain of Jupiter, but they come from the prior labours of many brains, and he is the true inventor who first collects the essence of and gives the stamp of vitality to those labours. In this sense the invention of steam navigation will for ever illustrate the name of Robert Fulton.

NORTH OF ENGLAND INSTITUTE OF MINING ENGINEERS.

The usual monthly meeting was held on Thursday, Feb. 5, in the rooms of the institute, Neville Hall, Newcastle-upon-Tyne; Nicholas Wood, Esq., president, in the chair.

After some other business, a paper on "Messrs. Donnisthorpe, Frith, and Hedley's coal-cutting machine, by Messrs. J. Daglish and L. Wood," was then read by Mr. Wood:—

ABSTRACT OF PAPER ON DONNISTHORP, FRITH, AND HEDLEY'S COAL-CUTTING MACHINE.

This machine, which is in successful operation, consists of an 8-inch cylinder, mounted on a frame fitted up with the ordinary tram wheels, moving along a tramway parallel to the face of the coal; the piston works a quadrant on a vertical shaft, and on the same shaft is attached a large coal pick, which by this means works in a horizontal plane, in a very similar manner to when used by the miner. The motive power used for working the machine is compressed air, which, at the West Ardsley Mine is obtained from a large receiver on the surface, into which it is pumped by a 30-horse power engine; it is conveyed from this receiver down the shaft in 4-inch metal pipes, and by 2½-inch pipes from that point to any part of the mine where it is required. The air is compressed to 55 lbs. per square-inch. Apart from any commercial considerations, there can be no doubt that a very considerable saving in the produce of large coal will be effected by the introduction of efficient machinery; and taking into consideration the great increase of consumption, and the already approaching scarcity of coal in some of the coal districts, the question becomes one of really national importance. The use of compressed air machines will also, in several ways, be of considerable advantage to the working miner; not only will it aid the working miner; not only will it aid the ventilation; but it will supply a current of air at a very low temperature, due to its sudden expansion, which will afford great physical relief in deep mines when the temperature is considerably elevated; further, the pipes, if carefully laid, would always be ready, in cases of explosion, to permit a current of pure air to be forced into those districts into which the atmosphere might be vitiated by the combustion of the gases. These machines will also relieve the miner of much of the more arduous, painful, and monotonous portions of his toil, especially in low and hard seams.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance. Post orders made payable to Mr. R. A. Brooman, of 166, Fleet-street, E.C.

Advertisements are inserted in the Mechanics' Magazine at the rate of 6d. per line, or 5½d per line for 6 insertions, 5d. per line for 13 insertions, 4½d. for 26 insertions, and 4d. a line for 52 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisments.

To insure insertion in the following number, advertisments should reach the office not later than 5 o'clock on Thursday evening.

No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of his good faith.

J. B.—N. B.—J. E. D.—J. W. R.—A. and P.—J. A. D.-J. O.—T. G.—G. R.—Capt. C. P. L.—J. N.—E. B.—J. P.

W. R.—Too full of personal matters. The letter is more fitted for our advertising columns.

Hoist.—We believe that there are about 3,000 collieries in England. They raise 80,000,000 tons of coal, probably worth at the pit's mouth, about £25,000,000.

S. B. Schiele's noiseless fan is arranged upon the same *general* principle as Lloyds; but it is carried out in a different manner.

E. P.—You should write to the Under Secretary of State for India, India Office, Victoria-street, Westminster.

Protection.—You are not allowed to make for your own use, without a license, anything covered by a patent or protected under the Registration of Designs Act.

A Boiler Maker.—We should object to the use of any chemicals for preventing incrustation in a steam boiler. Carbonate of soda is, however, recommended by Mr. Fletcher, of the Manchester Boiler Assurance Company, as will be seen in his report given in the present Number.

Correspondence.

SUBMARINE TELEGRAPHY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Whether a writer in your paper announces his name or writes anonymously, I apprehend that as long as he writes common sense, and his arguments on his subject are sound, it little matters to your readers, and I (for the simple reason furnished you), must still ask to remain what, in truth, I am, "An Old Sailor;" but, if Dr. Wallich considered my observations worth answering at all, he should have replied with temper (good I mean), and if his schemes are sound he should tenaciously keep to the point of the objections raised to them.

In stating mine to Dr. Wallich's sounding scheme, I mentioned the authority from which I derived my information, and which I believe to be substantially correct, so if your readers will take the trouble to compare my letter and the authority on which I based it, they will be able to judge if, "under the cover of an *incognito*, I have resorted to misinterpretations." Again, I assert that both the doctor's schemes are simply impracticable, the one as much so as the other. An illustration may be useful to prove it; and I will take well-known islands and rocks for my purpose, which have been visited many times by scientific officers with the best instruments. St. Paul's on the line, its position by the best authorities differ no less than 10 miles; Fernando Nevonhee, 8 miles; Trinidad, 10 miles. Now, if there is so much difference in results by different observers using an artificial horizon, and having all the advantage of shore observation, can Dr. Wallich assert that his *belt* can be kept, or that his submarine buoys would ever be found again, even allowing that they can be placed in position, which I deny; and yet I grant that the lines of soundings heretofore laid down in the charts to be "perfectly trustworthy, and not falsified records;" and every sailor will understand the nature of my belief, viz., that the position of each sounding is as correctly placed on the chart as it is possible to do by means of observations of all kinds at sea; and were you to ask any seaman how nearly that could be ascertained, he would probably answer, "within a few miles under ordinary circumstances."

If Dr. Wallich will take a chart on a large scale, draw the arc of a great circle across the ocean on the line Capt. Dayman was supposed to run, then with the positions recorded carefully prick them off on the chart, he will at once see that the line he proposes as the basis of his own was never run at all, and that almost every sounding will be to the right or left of the line.

But granting the line of soundings obtained, the doctor has not explained how he is going to run the cable over it, nor how he is going to moor his buoys to hold the line that is to be fast to the cable. (The doctor did not detect my error in stating that each of his buoys would have to support 4 miles of moving cable; on referring to his plan I see they would have to support 8 *miles!*")

I may propose to make a voyage to the moon, but if I did not explain the means by which I was to get there, I do not think my proposal would be dignified by being called a "scheme."

I am truly glad to hear that the doctor intends to tender his thanks for services rendered during his late cruize—tardy though they be. I have taken in many works in parts, but I have yet to learn that the latter part is "the only portion of the work in which a preface could be inserted."

Lastly, the doctor says, "to any knowledge of seamanship I have not pretended," yet in the last clause of his paper, addressed to the President and Council of the Royal Geographical Society, he says, "It rests with those who are competent to form an opinion on the subject, to determine whether or not my proposals deserve serious consideration; and also whether I am personally qualified to undertake the various researches indicated. Should I be recommended for the duty for which I have endeavoured to fit myself, I can only say my best efforts shall be put in force to do that duty well."

Whether any of those competent to form an opinion on the subject have considered the doctor's proposals deserve serious consideration, I know not; but all I have spoken to on the subject say they are not, and Dr. Wallich had better confess with a good grace that he has made a mistake.

Anxious as I and many are to see the bed of the ocean systematically examined, it must be by some other scheme than Dr. Wallich's, and I cannot think his exposition has done good to the cause.

As to being ridiculous, &c., the question simply is this:—Can either of Dr. Wallich's schemes be carried out? I say they cannot. Dr. Wallich says they can. One must be wrong; and that one is he, who has held himself up to ridicule, conferred trouble on the other, and occupied your space in vain.

I thank the doctor for his wish; the gout is better, but I laid no claim to the "spleen"—I leave that with him, and remain

Yours, &c.,
An Old Sailor.

TO ACCLIMATISE COTTON.

Sir,—Whatever may be urged to the contrary, I feel convinced that if the following plan is pursued, that the cotton plant may be acclimatised. So late in the season as the 15th of last July, I sowed the seeds of the *several* varieties of cottons (presented me by the Cotton Supply Association of Manchester) together, and in five days they broke ground, and at the end of four weeks they attained five inches in the open air. But they were sown too late in the season. Ginger, tamarind, and Indian corn, sown in a hotbed (as under) and then transplanted in the open air, will attain a good height in one season, the last arriving at maturity, and why not cotton?

Directions.—Plant the several kinds of cotton seeds together in a hotbed about the middle of *March*, and when the plants appear water freely. Select the most vigorous plants, in the middle of *April*, and transplant into a *slighter* hotbed for *three* weeks longer to encourage their growth. Then select the most vigorous plants again for transplanting in the open air in properly manured ground. But, if grown as a tree in our hot-houses, during successive years, and each year *gradually* exposed to low temperatures, the tree will in an advanced stage of growth resist our severe climate. In the south and west of England, the myrtle flourishes, produces blossoms, and seeds, in consequence of this process, as an *unprotected* standard tree; and the layers from such trees are much more hardy than the layers from myrtles reared within doors. The disposition of trees may be changed thus gradually, and a new climate be made supportable.

The "arbutus" has, from the same cultivation, become the principal ornament of the lakes of the south of Ireland. It thrives even in the bleakest mountainous situations. I am, &c.,

James Bruce.

Meetings for the Week.

Mon.—*Royal Geographical Society*, 1, "On the Discharge of Water from the Interior of Greenland, through Springs underneath the Ice," by Dr. H. Rink, of Greenland. 2, "On Rupert Land," by Captain Millington H. Lynge, R.E., at 8.30 p.m.
British Architects, at 8 p.m.
Tues.—*Inst. Civil Engineers*, 1, "On American Timber Bridges," by Mr. J. R. Mosse. 2, "On the Reconstruction of the Dinting and Motham Viaducts," by W. Fairbairn, Esq., at 8 p.m.
Royal Inst., "On Animal Mechanics," by Prof. Marshall, at 3 p.m.
Wed.—*Soc. of Arts*, "On the Best Means for Promoting the Supply of Cotton," by John Cheetham, Esq., at 8 p.m.
London Inst., "On the Zoology of Warm-blooded Vertebrata," by C. C. Blake, Esq., at 7 p.m.
Thur.—*Royal Inst.*, "On Chemical Affinity," by Dr. E. Frankland, at 3 p.m.
Antiquaries, at 8.30 p.m.
Royal Soc., at 8.30 p.m.
Fri.—*London Inst.*, "On the Chemistry of the Non-Metallic Elements," by F. Field, Esq., at 7 p.m.
Royal Inst., "On the Ancient Lake Habitations of Switzerland, at 8 p.m.
Architectural Assoc., Class of Design—Organ.
Sat.—*Royal Inst.*, "On the Science of Language," by Prof. Max Muller, at 3 p.m.

Since the substitution of steam fire-engines in Baltimore, the losses by fire have been reduced almost to *nil*. Last year the insurances ran up to 120,000,000 dols., while the absolute losses by fire do not exceed 15,000 dols., and this is in a city of at least 220,000 inhabitants.

Gossip.

A curious project has been set on foot by M. Faget, of Bordeaux, for the speedy conveyance of letters between England and France. He proposes to erect in both countries, at a distance of about 1,000 metres from the coasts of Calais and Dover, a strong edifice of masonry, containing a steam engine of sufficient power, by means of which an immense wheel, 25 metres in diameter, is made to turn 40 times a minute. By this rotation a series of wires, forming a gigantic strap extending across the Channel, is coiled round the wheel at one end—say Dover—and uncoiled at the other (Calais), and conversely. To this strap india-rubber letter-bags are attached, which are thus to be conveyed across the Channel at the rate of 3,000 metres per minute, so that, within the space of twelve minutes, the letters and despatches from one country may be landed in the other. The length alone of the strap is sufficient to cause its submersion, and the transmission might be effected in any weather.

The half-yearly report of the directors of the District Telegraph Company has been issued. It shows a net increase in the receipts of £1,406 7s. 4d., as compared with the corresponding period in 1861, and it is mentioned that the annual income of the company continues steadily to progress. A few additional contracts for private telegraphs have been undertaken where desirable, and amongst others telegraphs have been provided between some of the stations of the London Fire Brigade.

A bill has just been brought before Parliament to make general regulations in respect to all telegraph companies, existing and future, but not to affect existing companies in respect of a past exercise of powers. Much of the bill is of general interest and concern. No telegraph above ground is to be placed within ten yards of a dwelling house worth £20 a-year, or across an avenue or approach to such a house, without the consent of the occupier of the house. But a subsequent clause provides, that where the body having the control of a street consents to a telegraph being placed along it, that consent is to be sufficient authority for placing he telegraph along or over any land or building "adjoining to or near the street," but not directly over any building if the owner or occupier objects. Any person in the employment of a telegraph company wilfully or negligently delaying a message, or improperly divulging its purport, is to be liable to a penalty not exceeding £20. Every telegraph is to be open to all persons without favour or precedence, except that messages on her Majesty's service are to have precedence, if required by any department of the Government. Telegraphs also may be taken possession of for her Majesty's service, if the Secretary of State is of opinion that an emergency has arisen in which it is expedient for the public service that the Government should have control over the transmission of messages; the company to be compensated according to the average profits of the previous three months.

A Belgian glass-blower has lately blown two large bottles, each of a capacity of 62½ gallons, and weighing 50 pounds. They were blown at the glass-works of Lefevre and Co., at Lodelingart, and are nearly double the size of the largest bottles heretofore made.

A recent writer in the Toronto *Globe* says:—The question most eagerly asked of persons just come from Enniskillen, is generally the all-important one of whether the wells are holding out or not. It is a fact that many of the flowing wells have ceased to flow; and others, while still continuing to flow, do no longer yield the immense quantities that they did at first. But then, there remains yet untouched a large area of what there is every reason to believe to be good productive oil territory. The work of drilling and sinking wells is still vigourously carried on, and a rise in the price of crude oil to 1 or 2 dols. per barrel would set the drills going at a rate hitherto unheard of. The owners of wells which have ceased to flow do not think it worth while to drill down any further until a more remunerative demand arises for crude oil. When this takes place, every effort will be made, both by drilling further and pumping, to bring the oil up, if there is any to bring. The question whether former flowing wells will yield oil by pumping has yet to be determined. Oil Springs is certainly the busiest place of its size to be seen; in fact, a perfect hive of industry, full of life and motion. The population of the whole diggings is estimated at 2,000 or more. There are still more people than can find house-room to live in, and rents are of tiptop height. Landlords of houses appear to have taken "Excelsior" for their motto. Think of 6 dols. a month for the upstairs, merely, of a frame house about 18 by 24, and three or four competitors for that. People continue to come in faster than houses can be built for them. The hotels and boarding houses are crowded, and the unfortunate inmates are fairly lost for want of a place to go to in the evening, and even for seats to sit upon after supper time.

At a recent meeting of the Manchester Literary and Philosophical Society, Dr. Joule described a barometer for measuring small atmospheric disturbances. It consists of a large carboy connected by a glass tube, with a miniature gasometer formed by inverting a small platinum crucible over a small vessel of water. The crucible is attached to the short end of a finely suspended lever, multiplying its motion six times. When the apparatus was raised two feet, the index moved through one inch; hence he was able, in serene weather, to observe the effect corresponding to the elevation of less than one inch. The barometer is placed in a building, the slated roof of which affords, without perceptible draught, free communication with the external atmosphere. In this situation it was found that the slightest wind caused the index to oscillate, a gale occasioning oscillations of two inches, an increase of pressure being generally observed when the gusts took place.

Mr. Joseph Sidebotham exhibited, at a recent meeting of the Manchester Philosopical Society, a cornelian pebble with a cavity containing a globule of water, brought from the coast of Tuscany. These pebbles are often picked up on the shore, and when broken exhibit a crystalline cavity about one-third filled with water.

Steel for Fire-arms.—Captain Caron has been for some time addressing papers to the Academy of Sciences about his experiments on steel, effected at the Depot des Poudres et Saltpètres, for the purpose of applying that metal to ordnance and fire-arms in general. More than twelve months ago, samples of a peculiar soft steel were brought to the artillery factories, and the remarkable qualities of this metal induced Colonel Trielle de Beaulieu, the director, to apply it to the manufacture of tubes intended to protect the copper of the points of sight of heavy ordnance. This steel has the property of drawing cold, in tubes of any dimensions, and after drawing—above all, if the metal be tempered—the grain, perfectly homogeneous, is fine and watered, the steel has become strengthened (*nerveuc*), and offers an extraordinary amount of resistance. Since then gun-barrels, manufactured from the same material, have been presented to the factory for the models of arms, and Captain Maldin, director of this establishment, struck by the beauty of the metal, thought it his duty to try the barrels, in order to establish their quality. The following are the very curious results at which this officer has arrived:—A gun-barrel of the ordinary dimensions of that of a sporting gun, after having been trued, was tried first with 30 grammes (1 oz.) of powder, and one ball of 37 grammes (1¼ oz.) This charge producing no deterioration was followed by trials with a ball of the same size, and in increasing the charge by 10 grammes at a time up to 60 grammes (2 oz.). The 60 grammes were then replaced by 40 grammes of extra fine Esquerdes powder (the most destructive powder known). Not being able to burst the barrel, the experiments were continued with gunpowder, and after some trials, a charge of 150 grammes (5 oz.) was arrived at without inducing a rupture. A last experiment was then tried, in which 150 grammes (5 oz.) of powder and five balls were employed, the latter weighing together 135 grammes (say 4¼ oz.) well rammed home. The only injury seen was a swelling in the barrel at the spot where each of the balls was placed, but the barrel was not burst, not even cracked. If it be considered that the charge of powder was already 23 in. long, and that a more considerable quantity would not have had time to burn entirely, it may be fearlessly concluded from these experiments that the metal employed in the manufacture of these barrels is capable of giving arms which cannot be burst by the effort of any charge of powder whatever.—*Galignani.*

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 2094, 2095, 2110, 2117.
Boilers and Furnaces, 2103.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 2109, 2119.
Ships and Boats, including their fittings, 2083, 2115, 2116.
Cultivation of the Soil, including agricultural implements and machines, 2082, 2097.
Food and Beverages, including apparatus for preparing food for men and animals, 2112.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 2078, 2081, 2085, 2091, 2098, 2104, 2111.
Buildings and Building Materials, 2099, 2105.
Lighting, Heating, and Ventilating, 2096.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 2080, 2092, 2114, 2118, 2120.
Metals, including apparatus for their manufacture, 2100, 2101.
Chemistry and Photography—*none.*
Electrical Apparatus—*none.*
Warfare, 2079, 2102.
Letter-Press Printing, 2017.
Miscellaneous, 2084, 2086, 2087, 2088, 2089, 2090, 2093, 2106, 2108, 2113, 2121.

2078. S. Lord and J. Lord. *Improvements in carding engines.* Dated July 22, 1862.

This invention consists, first, in improved modes of stopping the motion of the doffing cylinder, and feeding rollers, when a sliver is broken at any part, and does not enter the can or coiler. From the shaft which drives the can or coiler, the patentees give motion by a worm and wheel, spur, or bevel gearing, to a catch box on the upright of the coiler, thereby dispensing with wheels. The loose part of the catch box is forced out when the sliver breaks, or cannot enter the can or coiler by causing it to be held by a rod connected to the trumpet or balance lever. As the loose part of the catch box is moved out, it operates upon an incline or cam at one end of a double lever, the other end of which releases a catch and allows the barrow handle to be lowered, and bring the pinion out of gear and stop the engine whenever there is a breakage or defect in the sliver, without in any degree depending upon its tension. Secondly, in an improved mode of working the doffing knife or comb. They form in the doffing stock which holds the knife or comb a hole from end to end, through which hole they pass a shaft, having fixed to it two or more eccentrics which fit the hole, so that, when the shaft and excentrics revolve, an excentric movement is given to the knife or comb, which thereby strips the cylinder in a very efficient manner without injuring the card. *Patent completed.*

2079. P. F. Cassegrain. *Improvements in firearms.* Dated July 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2080. A. Fournier. *An improvement in the manufacture of easy chairs, railway and carriage seats, seats of any kind, and mattresses.* Dated July 22, 1862.

In carrying out this invention, the inventor places (instead of the ordinary webbing) bands of vulcanised india-rubber across the frame of the chair, or other seat or mattress, vertically and horizontally, interlacing them, and refixing them to the framework, making by this means an elastic foundation, after which the chair or other seat or mattress is stuffed in the ordinary manner; and in this way he also constructs the backs of chairs where they are stuffed or padded. *Patent completed.*

2081. D. W. Smith. *Certain improvements in power looms for weaving.* Dated July 22, 1862.

This invention relates to that portion of the loom known as the yarn beam, and consists in the novel application thereto of a break in the form of a circular hinged band, having a projecting piece attached. The hinged circular band may be made of metal, or other convenient material, and encircles the neck of the yarn beam, the friction thereupon being obtained and regulated by a screw passing through the ends of the band, and thus the revolution of the yarn beam is governed in a more simple manner than by means of the ropes and weight as hitherto. The projecting or tail-piece of the break bears against a stud or spring to prevent the break turning with the beam. *Patent abandoned.*

2082. J. Daniels. *Certain improvements in artificial manure.* Dated July 22, 1862.

This invention consists in grinding raw or unboiled bones for the purpose of producing a manure more rapidly beneficial to the land than where the said bones are cut or rasped. When bones are ground, the manuring properties thereof are expressed and brought to the surface, and in such state are more readily mixed with the land; but when cut or rasped it requires a considerable time to impregnate the land with the manure. *Patent completed.*

2083. R. Grogan. *Increasing the speed of screw-propeller steam-vessels.* Dated July 22, 1862.

This invention consists of certain vanes, or blades, of a flat, spiral, or other suitable form, two or more of which are mounted upon or attached to shafts, cranks, or beams, and wholly or partially submerged at, or in, or partially with, the sides, bottom, or stern of the vessel, where the same, when fitted to the required mechanism, can be made to act as a paddle, or take the place of a screw-propeller. The propeller is two-bladed, and its general form is that of a segment of a disc, or a parallelogram, which is made to rotate transversely upon or about an axis which traverses the blade, or upon which the blade traverses longitudinally. In constructing the propeller, the ends of the blades may be made of a spiral form, and one or more of these blades may be fitted either entire or in sections, so as to form a screw, or paddle, with two, three, four, or more, propelling vanes; by preference, however, the patentee uses a simple two-bladed propeller, the two vanes of which are in the same plane, or in planes at right angles, or inclined to each other. When the two vanes, or blades, are not in the same plane with each other, they are mounted so as to turn partially upon or about their respective longitudinal axis or axes, so that, as one paddle, or vane, enters the water flatways, the other vane leaves it edgeways, so as to enter and leave the water angularly, more or less, as circumstances may require. As these blades rotate about their transverse axes, they have a transversing motion longitudinally, in order to increase their stroke and dipping or propelling surface. *Patent completed.*

2084. W. E. Gedge. *An improved instrument for marking wadded or other stuffs.* (A communication.) Dated July 22, 1862.

This apparatus is composed of a cylinder, usually from 2in. to 4 in. long. On this cylinder is placed a disc, or discs. The ends of the cylinder carry a short spindle, to allow of its being secured in a frame, which tapers up to a handle. Grooved slides, either framed or not (but with means to retain them in parallel), are placed upon the stuff to be operated upon. The cylinder, and consequently the disc or discs, being heated, the operator takes the instrument by the handle aforesaid, and pushes it along the grooved slides, and the disc, or discs, mark out the squares upon the wadding, or stuff, which is to be placed upon a table, the surface of which may, with advantage, be slightly stuffed, or padded. By altering the position of the grooved slides, different sized square lines or lozenges may be impressed upon the stuffs. *Patent abandoned.*

2085. W. Crofts. *Improvements in the manufacture of fabrics by lace machinery, and in the means or apparatus employed therein.* Dated July 22, 1862.

The object of this invention is to produce various ornamental effects in fabrics by lace machinery. The inventor obtains a looped pile effect upon weaving, or opaque work, and between or upon pillars of fabric produced in twist lace machinery, by causing warped threads to be looped around holding out instruments, upon which such warp threads are wound whilst they are being tied into the fabric by other warp and bobbin threads. *Patent abandoned.*

2086. H. R. Summons. *An improved apparatus for bordering envelopes, paper, and cards.* Dated July 22, 1832.

This invention consists of an improved apparatus, by aid of which envelopes, paper, and cards, may be furnished with a bordered, black, or ornamental edge, with greater rapidity and regularity than by the means adopted for such purposes. The inventor proposes to fix on the surface of a bar of wood a metallic plate, the surface of which is provided with a series of indentations, or serrated edges, equidistant to each other. These serrated grooves are to be cut in an angular form—that is to say, they should form a right angle at or near the centre of the metallic plate, and the envelopes, paper, or cards, are to be placed or laid down on the metallic plate with their edges abutting against the edges of the steps, which the vertical faces of the indentations afford, and by means of which a numerous series of envelopes, cards, or paper, may be placed in such a position that their edges shall be respectively and equally paralled to each other. Or, in lieu of a plate, he proposes to lay and fix on the board a series of angular shaped slips or pieces, the edge of one overlapping the edge of the next, so as to form a series of serrated surfaces, similar to those presented by the serrated plate. In addition to the serrated edges he proposes, as an auxiliary to the aforesaid means of keeping the articles in position, to employ a series of narrow slips of cord, metal, or other material, fixed and inserted in the surface of each sloping groove, and underneath the next or high edge of the serrated groove, in such a manner that the edges of these slips shall just overlap the edges of the articles to be bordered as they are placed in the grooves, so as to hold them down, more securely during the process of arranging the series. Each side of the bar or board is furnished with a narrow hinged flap, which is opened during the foregoing process, but which is closed over the edges of the board on which the articles have been placed, so as to press upon their corners (and aided by thumb screws or other pressure) to hold them down while the process of bordering takes place, by means of brushes, as is ordinarily done. It will then be necessary to change the position of the envelopes, or other articles, in order to expose their opposite edges or borders to the action of the brush. He proposes to place under the edges of the articles, and on each side of the serrated plate previously to shutting, over the flaps, a slip of metal, in order to form a bearing surface for the flaps, and prevent the articles being pressed down on to the board itself, which would crease or damage the envelopes, cards, or paper. The serrated edges may be cut in any desired form, according to the shape of the article to be bordered; they may be set at any required angle, or on the square—that is to say, the grooves may be cut perpendicularly across the plate, or they may be cut in curvilinear grooves, and at any required distance apart, in order to suit any outline, and any width which it is desired to give to the margin of the envelope, paper, or card to be bordered. *Patent abandoned.*

2087. H. R. Summons. *Improvements in machinery or apparatus for bordering envelopes, paper, and cards.* Dated July 22, 1862.

In carrying out this invention, the inventor proposes to bolt or screw to a table, on standards, an iron bed plate, on which a raised block is fixed, having a smooth, flat surface, two sides or edges of which correspond with the shape of two edges of the envelope, paper, or card to be bordered. Underneath the table, and hinged to the standards, he arranges a treadle, from which extend vertically, through the bed plate, connecting rods, one of which is attached to a metal slide fitting against the two edges of the block, and raised a little above the surface thereof. This slide acts as a stop, and enables the envelope or other article to be bordered to be placed on the block by hand, exactly parallel with its edges. Another connecting rod passes through the opposite end of the bed-plate, and draws down an arm or lever of the second order attached to a hinged fulcrum between two pillars. The extremity of this lever is furnished with a thin, flexible steel plate, which is held above the block, and the edges of which plate, although parallel to the edges of the block, do not correspond therewith, but are so situated that, when pressed down upon an envelope or other article placed upon the block, they may leave two sides of the envelope, paper, or card exposed. The treadle being still further operated, the other connecting rod will draw down the sliding stop from the edges of the block, and the envelope or other article is then so exposed that it may be bordered by means of a brush. *Patent abandoned.*

2038. T. King. *Improvements in apparatus for measuring grain and other granular substances.* Dated July 22, 1862.

For the purposes of this invention a measurer is employed having two circular ends, the space between the two ends being divided radially by partitions, so as to produce angular measuring chambers around the central horizontal axis, and on which the measurer is caused to turn. The axis of the measurer turns in bearings carried by the framing of the machine, the upper portion above the axis being covered in by a bent plate or cover in the form of a semi-circular arch, which is fixed to the framing. There is an opening through such cover where the lower end of a hollow trunk or pipe is attached, which trunk or pipe descends from an upper floor, chamber, bin, or place from which the malt or grain or other granular substance descends through the trunk or pipe to the measurer. In the hollow trunk or pipe is a valve, the axis of which has a weighted lever fixed on it, and such lever is arranged to act on the driving strap (which communicates rotatory motion to the axis of the measurer) and causes such driving strap to be moved from the driving pulley on to the loose pulley, when the weight of the lever overcomes the valve by reason of the supply of malt or granular substance being insufficient, and the machine will thus be stopped; but so soon as the weight in the valve caused by an increased supply of the substance to be measured is sufficient to overcome the weighted lever, the driving strap will be again moved from the loose pulley to the fast one, and the machine be again put in motion. The driving pulley is on an axis on which there is a worm or screw, which gears with and drives a worm or screw wheel in the axis of the measurer. The malt, grain, or other granular substance is delivered from the measuring compartments as the radial partitions descend below the axis of the measurer. The measuring chambers or compartments are each capable of measuring a bushel or any other determined quantity of material. *Patent completed.*

2089. G. Payne. *Improvements in horse-shoes.* Dated July 22, 1862.

According to this invention, it is proposed to form a number of transverse grooves, channels, or indents, across the metal of the shoe, so as to leave alternate hollows and projections. The nail holes are made in the thicker or projecting portions and thus obtain a firm hold of the shoe. *Patent abandoned.*

2090. J. H. Johnson. *Improvements in the treatment or the noxious gases or vapours produced in the distillation or purification of tar.* (A communication.) Dated July 22, 1862.

This invention consists in causing such vapours to pass from the "etouffoir" or closed chamber, wherein the solid matters are deposited, into a second closed chamber, in place of allowing them to pass off direct into the atmosphere. The pipes which connect the first chamber with the second are inclined, so as so allow the napthaline and other products to pass freely into the second vessel with the vapours. A second pipe of considerable length connects the upper part of the second chamber with a furnace or fire-place, which effectually consumes the noxious vapours as fast as they enter the furnace, the harmless products of combustion passing off by a flue to a chimney. When the solid matter is withdrawn from the "etouffoir," it may be placed in a receptacle beneath a hood, which is also in communication with the furnace, so that the vapours arising therefrom may also be consumed in place of escaping direct into the atmosphere. *Patent abandoned.*

2091. A. C. Vautier. *Improvements in obtaining fibrous materials, and in manufacturing paper pulp, also in preparing, bleaching, and treating fibrous materials and fibrous and textile fabrics, and in producing agents used in part of the invention.* Dated July 22, 1852.

We cannot here give space to the details of this invention. *Patent completed.*

2092. J. J. Haley. *An improved machine for wringing clothing and other woven fabrics.* (A communuication.) Dated July 22, 1862.

This invention consists in the novel construction and arrangement of the various parts of a machine more especially designed for squeezing or forcing water from clothing and other fabrics, but which may be used without alteration for washing or expressing dirt from the same, and also to expedite the process of starching. These improvements relate to various methods of exerting the pressure upon the two rollers employed to properly adjust them to the thickness of the material or articles passed through the machine, to modes of fixing the machine firmly upon the tub or washing vessel, to a water-guide or slanting board for conducting the water back into the tub, and to a novel manner of attaching rolls of india-rubber, or other similar material, to shafts by which they are firmly secured, and chemical action, which takes place when the rolls come in contact with metal, is prevented. *Patent completed.*

2093. C. J. Keene. *A new or improved winding apparatus for raising and lowering canvas on easels.* Dated July 23, 1862.

This invention has, for its object, the adjusting with greater facility than has hitherto been done the position of the frame or rest board of easels on which the canvas is placed, and is constructed in the following manner:—To the back of the moveable frame is attached the working apparatus, consisting of a crown wheel through the centre of which a spindle is attached worked by a key or handle, and to which is geared a small toothed wheel attached to a worm or screw which lies within the circumference of the crown wheel, which worm or screw works in a rack screwed on the front of the central vertical piece. The turning of the key or handle causes the crown wheel, by means of the small toothed wheel, to work the worm or screw up and down the rack, and carries with it the frame and rest board upon which the canvas is placed. *Patent completed.*

2094. Z. Colburn. *Improvements in apparatus for the condensation of steam in steam-engines.* Dated July 23, 1852.

The air pump, as ordinarily used in condensing steam engines, performs two distinct purposes, the first of which is the removal, from the lower part of the condenser, of the condensed steam and injection water constantly collecting there, while the second purpose is the removal of air brought in with the injection water, and, to some extent, introduced through slight leaks in the condensing apparatus itself. Now the inventor dispenses with the air pump, and accomplishes its two purposes in the following manner:—Whenever he can obtain a clear fall of not less than 30 ft., or, which is better, 33 ft. below the lowest part of the condenser, he allows the injection water and condensed steam in the condenser to run off by their own gravity, and in opposition to the external pressure of the atmosphere, the overflow or discharge through which they descend having its lower or discharging end kept constantly under water, so that no air may enter it, and thus gain access to the condenser. This mode of keeping the condenser clear of water has been already occasionally employed by engineers, but not in a manner to dispense with the air pump. Where the inventor cannot obtain a clear fall of 30 ft. from the condenser, so as to discharge the water by its own gravity, and in opposition to the pressure of the external atmosphere, he then employs a force pump—which he prefers should be a centrifugal pump—to force out the water from the bottom of the condenser. The removal from the condenser of the air brought in with the injection water, and the air also introduced through leaks in the condensing apparatus itself, is as follows:—He employs for this purpose a vessel which he calls the hydraulic exhauster, and which vessel he places at a level somewhat above that of the condenser. The hydraulic exhauster is a vessel so fitted with valves that it may be first filled with water, and any air within the vessel will be thus expelled at the same time through a self-acting valve, after which the water in the exhauster may be emptied into the condenser, or into a vessel suspended within the condenser. The space which the water previously occupied in the exhauster will then receive a share of whatever air may be collected in the condenser, and in this manner the exhauster will perform the purpose of the ordinary air-pump in abstracting air from the condenser. The communication between the exhauster and condenser being then closed by a valve worked by the engine, and the exhauster being again filled with water and its contained air thereby expelled through a self-acting valve, it will repeat the operation previously described, and by being constantly worked in the manner hereinbefore explained, it will keep the condenser constantly free from air, except at the very low tension at which air is generally present in all good condensers. The water admitted to and discharged from the hydraulic exhauster in the manner described is afterwards used as injection water for condensing the steam in the condenser, this steam being the exhaust steam of the engine to which the apparatus herein described is applied. When the lower valve of the hydraulic exhauster is opened, and held open by means of mechanism worked by the engine, the water in the exhauster will fall through a pipe or other suitable passage into an open topped vessel suspended in the upper part of the condenser. From this vessel the water will flow out through a suitable injection nozzle or pipe, either fitted or not fitted with what is called a "rose," and thus the water will run into the lower part of the condenser, condensing the steam on its way. *Patent abandoned.*

2095. E. K. Dutton. *Certain improvements in steam engines.* Dated July 23, 1862.

This invention relates, principally, to that portion of the steam-engine generally known as the slide valve, and to apparatus connected therewith, and consists, first, in admitting the steam to the inside of the valve through a port in the valve face usually cast on the cylinder, the said port, by preference, corresponding in position to the ordinary exhaust port, the exhaust steam passing into the valve box. The valve may be of a similar form to that ordinarily used for "high pressure" engines, suitably furnished with a plate on the back, or other equivalent, to keep it to the face on the cylinder; or it may consist of a block or plate with a port through its centre sliding between an adjustable plate and the valve face constituting what is known as an equilibrium valve, the plate on the back of the valve sustaining the pressure of the steam. The second part of the invention is designed principally for the purpose of saving a portion of the steam usually lost in the passage between the ends of the cylinder and the valve; and the improvement consists in making the valve sufficiently long to discharge the steam into ports formed at or near each end of the cylinder, the steam being admitted to the centre of the valve from a port or ports in the valve face, and thence through passages, cast or formed in the valve, to the cylinder ports through openings or cross passages at each end of the valve, which said cross passages, together with the opening in the centre of the valve, are open through from front to back, and are closed at the back by a plate or plates between which and the valve face the valve slides. The said plate or plates are adjusted in distance from the valve face by means of screws or bolts, and nuts, springs being added to sustain the pressure of the steam, if preferred. The exhaust steam may either be allowed to pass into the valve box, or it may be conducted to openings in the valve face through passages formed in the valve, or partly in the valve and partly in the adjustable plate, in which case the valve box may be opened for the adjustment or inspection of the valve during the working of the engine. The third part of the invention consists in a novel method of cutting off the steam from the cylinder at any portion of the stroke when working expansively. *Patent abandoned.*

2096. A. Vignon. *Improvements in the means and apparatus for extinguishing fire, either on land or water.* (A communication.) Dated July 23, 1862.

The patentee claims,—1, The employment of a solution of carbonic acid gas, in water, either at a high or low pressure, for extinguishing fires on land or on board vessels. 2, The construction and employment of apparatus, either portable or fixed, for extinguishing fires, in which a solution of carbonic acid gas in water is prepared and stored up, and whence such solution is ejected with sufficient force without the aid of pumps. *Patent completed.*

2097. W. Clark. *Improvements in the manufacture of manure.* (A communication.) Dated July 23, 1862.

This invention relates to the manufacture of manure, termed "animalized lime," and consists in treating quick lime, which is slaked by sprinkling it with urine sewage water, or other fertilizing liquid, to which may be added pure water in certain proportions, according to the state of the lime and the matter to be treated. *Patent completed.*

2098. E. Alcan. *Improvements in machines for combing and carding wool and other filamentous materials.* (A communication.) Dated July 23, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2099. R. Bell. *Improvements in the manufacture of bricks.* (A communication.) Dated July 23, 1862.

This invention consists in certain improvements in the manufacture of bricks, by means of which they are enabled to register with each other in the process of building, and to bind the work together in such a manner that it shall form a mass incapable of being riven asunder or cracked. The bricks are to be formed with projections or tongues across or along one surface, and with grooves or recesses of corresponding size on the opposite side, whereby they may be laid down one on the other, with the aid of a small quantity of mortar or Portland cement, in such order as to fit or bind together the upper layer with the lower layer, and to tie each other longitudinally and crosswise, so as to prevent any lateral or transverse deviation or fissure occurring in the work. With regard to bricks for arches, a similar system of construction is adopted, by means of which it is evident that centres will not be required in the construction of arches and vaults, for as soon as one single layer of bricks has been thrown across the arch the series may be continued by inserting the second layer into the first, into which it will register and be self-supporting, and so on with the entire length of arch, or tunnel, or vault. *Patent completed.*

2100. J. Leetch and B. Mathew. *New and improved method of protecting the surfaces of iron or other metal work from oxidization, incrustations, or accumulations of any kind, more especially in the cases of ships' bottoms, steam-boilers, and machinery.* Dated July 24, 1862.

This invention is intended to be applied, chiefly, to metal ships, or to metal plates to be employed in the construction of ships, but it is applicable to metals and metallic surfaces generally. The invention consists, first, in protecting the iron by means of a glaze or vitreous compound, or by means of glass applied in a manner which we cannot here quote in detail. The second part of the invention consists in fixing glass upon metal surfaces with the interposition between the metal and the glass of a composition, which not only serves as a cementing medium, but also acts as a soft cushion for the glass. *Patent completed.*

2101. J. Dickson. *Improvements in treating copper ores and solutions of copper, to obtain copper therefrom.* Dated July 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2102. J. Horton. *Improvements in breech-loading firearms.* (A communication.) Dated July 24, 1862.

This consists in certain improvements in breech-loading firearms, whereby the firearm is charged with bullet and powder, and primed with a percussion cap, and the parts of the lock brought into position for firing by the depression and subsequent raising of a lever, situated on the under side of the gun, and forming the trigger guard. *Patent abandoned.*

2103. W. Clissold. *An improved mode of manufacturing cylinders.* Dated July 24, 1862.

This invention consists in manufacturing cylinders of wood and iron, as described with reference to the drawings. *Patent completed.*

2104. H. Rawson and F. Staples. *Improvements in machinery for combing wool and other fibres.* Dated July 24, 1862.

This invention has reference to a previous patent dated 28th April, 1860 (No. 1083.) In the machine described in the specification of that patent, a moving comb, called a reciprocating comb, is used, in combination with a travelling comb, so that, when the two combs are together, the sliver or fleece of wool or other fibre is placed into the teeth of the two combs, so that the end or fringe of the fibres projecting beyond the teeth of the reciprocating comb is placed in and beyond the teeth of the travelling comb. According to these improvements, the reciprocating comb is formed of three parts, two of which are fixed to the reciprocating table which carries the reciprocating comb. A space is left between the two fixed parts, in which the third or moveable part of the reciprocating comb is placed; and such third part is capable of being moved independently of the other two parts, which simply move with the table to and from the travelling comb (as described in the previous patent), so that the protruding fringe of the sliver or end of the fibres may be placed into and left in the teeth of the travelling comb. The sliver of wool or other fibre is out of the teeth of the reciprocating comb at the time the reciprocating comb comes up to the travelling comb. The sliver of wool or other fibre, when the travelling comb and reciprocating comb have come together, is pressed into the teeth of both of them; the reciprocating comb is then moved away from the travelling comb at this time. In the present arrangement, the third or moveable comb is traversed in the space which divides the two fixed parts of the reciprocating comb, and its movement is in a direction towards the travelling comb; by this movement the wool or other fibre across the space between the two fixed parts of the reciprocating comb will be combed. The sliver is then lifted out of the teeth of the reciprocating comb, and the third or moveable part of the reciprocating comb is traversed back, whilst the sliver is out of the teeth of the several parts of the reciprocating comb. The sliver also, whilst it is out of the teeth of the reciprocating comb, is moved a distance forward, so that that part of the projecting fringe of the sliver in which the wool has been accommodated by the third or moveable part of the reciprocating comb, when the combs next come together, be placed into the teeth of the travelling comb. *Patent completed.*

2105. T. Lemaistre. *Improvements in privies.* Dated July 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2106. J. G. Clarke. *Improvements in scythes.* Dated July 24, 1862.

This invention consists in forming the heel of a scythe blade with a recess, and so that it may be fixed by a wedge in a hollow socket, which is fixed or formed, by preference, on the end of a tube, which is passed into and fixed in a hole formed up the lower end of the sneath or handle of a scythe. *Patent completed.*

2107. W. H. Perkin. *Improvements in printing and dyeing when aniline and analagous coal tar dyes are employed, also in preparing colouring matters.* (A communication.) Dated July 24, 1862.

According to one part of this invention, in printing and dyeing with aniline and analogous coal dyes, the patentee uses as a mordant, arsenious acid, or a salt or compound thereof, and this he uses in combination with alumina. In printing, he prefers to mix together arsenite of soda, acetate of alumina, and the dye, then to print the fabric with this compound, and afterwards to steam it; the several materials may, however, be applied separately. The colouring matters which he prefers to employ are those known commercially as "aniline purple," "violet imperial," "regina purple," "Cleu de Lyon," and "Magenta." The following method of preparing the mordant for use with the colouring matter for printing is applicable more especially when "aniline purple" or "violet imperial" is used:—To two parts of acetate of alumina, having a density of 10 deg. Beaume, eight parts by weight of arsenite of soda are added, and after well stirring this mixture the colouring matter is added either in the form of a fine precipitate, or dissolved in any convenient solvent, in the proportion of about 16 parts of dry colouring matter to the 1000 parts of acetate of alumina. If the precipitated colour be used, it is best to use it in a wet state. When Magenta is used a better result is obtained, if 136 parts of arsenite of soda be used instead of 80 parts. The colours thus prepared are thickened with starch, gum, or other suitable material, and printed on to the fabric, which is then dyed, steamed, and washed in the usual way. *Patent completed.*

2108. W. Clark. *Improvements in machinery for the manufacture of fishing and other nets.* (A communication.) Dated July 24, 1862.

The patentee claims the improved machinery for the manufacture of fishing and other nets (as described and represented in the drawings) which consists in reducing the number of the working parts, so as to render their action more direct, and permitting of greatly increasing the speed at which the machine is driven, and reducing the labour, and, consequently, the cost at least one-third. He also claims the friction mechanism as and for the purposes described. *Patent completed.*

2109. M. Henry. *Improvements in apparatus for retarding and stopping carriages, especially applicable to railway carriages, and in disconnecting apparatus for carriages.* (A communication.) Dated July 24, 1862.

According to this invention breaks may be applied and caused to stop or retard carriages by the action of uncoupling or disconnecting the carriages from each other, in the case of trains. In one arrangement a chain or like agent, extending to within easy reach of the driver or other attendant, is connected under each carriage to a bar, rod, or shaft, called a disconnecting shaft. Each coupling hook is held to the carriage by a bar, rod, or piece, herein called a "key," kept in place by a moveable notched or hooked piece connnected to the disconnecting shaft by a crank link or jointed lever. When the chain is pulled or drawn, the disconnecting shaft is turned partially round, or oscillated, so as to move the notched or hooked piece, and release the key therefrom, whereupon the key is forced upward by a spring, and liberates the coupling hook from the carriage, an action which the momentum of the latter facilitates. The same action of the disconnecting shaft that disconnects the carriages also works the breaks. For this purpose the said shaft operates the breaks preferably through links, arms, or cranks actuating the links. *Patent abandoned.*

2110. H. A. Jowett. *Improvements in obtaining motive power, and in transmitting the same from place, and in apparatus connected therewith.* Dated July 25, 1862.

Here the patentee proposes to obtain compressed air as a motive power for transmission by pumps for that purpose worked by steam engines, and by pipes or tubes connected therewith to collect the same into reservoirs or receivers. The reservoirs or receivers will be supplied with air gauges for the purpose of always ascertaining the precise pressure thereon, and regulating the same. There will also be safety-valves on each reservoir or receiver, in the manner used for ordinary steam-engine boilers. He proposes also to obtain compressed air as a motive power for transmission by a fall of water in tidal rivers or reservoirs of water, having a natural or artificial fall of water, to set in motion the requisite machinery, that is to say, water-wheels, turbines, Barker's mill, or hydraulic ram, for working pumps to condense or compress air, and through pipes or tubes to collect it into reservoirs or receivers, and to transmit such air from one place to another, where motive power is required, by one or more main pipes or tubes placed under streets or highways, or otherwise connected with the central reservoir, or one of the branch reservoirs, as is adopted by gas and water-works establishments. *Patent completed.*

2111. J. Redgate and H. Redgate. *Improvements in machinery or apparatus for the manufacture of fabrics on bobbin net or twist lace machines.* Dated July 25, 1862.

This relates to apparatus known as the circular, the levers, and the single and double-locker machines, and consist in an arrangement in which the patentees employ a bar in or upon which is secured a number of instruments, each of which is somewhat thicker in depth than in width. Each instrument has a slot in the direction of its depth proceeding from the upper side thereof; in this slot is a thin bar which has a knife edge on its lower side, and is free to move endwise, and upwards and downwards, such movements being effected by a mechanical contrivance at one or both ends of the machine. They lower these instruments to a certain depth, and bring the front and back point bars in their turn upward between these said instruments, and place one, two, or more warp threads in front of the centre of the machine, and the requisite number for making the fabric at the back of the centre of the machine. The threads in front, as they are traversed to the right and left, are taken up by the point bars, one or more of such warp threads passing round one or more of the before-mentioned instruments, and also passing round one or more of the bobbin threads to form a looped pile on the face of the fabric. When they wish the pile to remain uncut, they use the said instruments without a knife, and cause them to be brought slightly forward at the same time as they rise out of the pile, when the instruments will again descend ready for forming another series of piles. But when they desire to form a cut pile on the fabric, they dispense with the forward and upward movements of the instruments, and keep them stationary, using the knife, to which they communicate motion as above described, so that as the pile is formed and the fabric is carried up to the work beam, the knife will cut the pile and free the work from the instruments. In either case, however, they sometimes shog the instrument bar to the right and left one or two gates, according to the fabric required to be made, and the number of instruments used. *Patent completed.*

2112. J. Anderson. *Improvements in separating gluten from starch, and in preparing gluten for food.* Dated July 25, 1862.

The patentee claims, 1, the separating of the gluten and starch of wheat flour by the action of a revolving shaft with arms in a trough, aided by jets of water, substantially a described. 2. The using of warm water to assist the separation of the gluten and starch, as described. 3. The coagulating or converting of the gluten by heat, substantially as described. 4. The completely drying of the gluten after coagulation, substantially as described. 5. The preparing of the gluten for food, substantially as described. *Patent completed.*

2113. P. Robertson. *Improvements in producing brushing or frictional surfaces.* Dated July 25, 1862.

This relates to the production of brushing or frictional surfaces of vulcanized or manufactured rubber in an improved manner, and it consists in moulding the rubber in sheets of convenient size, the moulds being shaped so as to produce on one side of the sheet a series of short projecting points or pins, which points or pins form the actual brushing or frictional surface. *Patent completed.*

2114. W. Clark. *An improved apparatus for decanting wine.* (A communication.) Dated July 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2115. J. Seymour and D. G. Hatcher. *Improvements in steering ships, and in apparatus for the same.* Dated July 25, 1862.

This relates to the application of blades or surfaces to both sides of ships for the purpose of steerage, either as an auxilliary to the ordinary rudder, or in case it should be carried away. These surfaces the inventors prefer to place on each quarter of the ship at a sufficient depth below the water line, and they recess them in the side of the ship, so that when not in use they are flush, and present no obstacle to the passage of the vessel through the water. Each of these surfaces are mounted on an axis or pivot at the forward part, and have motion thereon similar to the action of the rudder; this may either be communicated through the axis itself, or by a curved bar fixed to the plate or surface, and passing through a stuffing box in the ship's side; the curve is described by a radius taking the pivots as a centre. *Patent abandoned.*

2116. W. Clark. *Improvements in rafts or structures applicable for the ordinary purposes of marine and inland navigation, as also for saving life in cases of shipwreck or otherwise.* (A communication.) Dated July 25, 1862.

This apparatus is formed of four barrels, tuns, or hollow cylinders, carrying a light bridge-like structure. The inventor also applies this principle for the purposes of navigation. Thus he proposes to use hollow barrels or closed cylinders, each having a longitudinal axis, which allows of their turning so as to obey the least tractive force. *Patent abandoned.*

2117. V. Manzini. *Certain improvements in the construction of locomotive engines used on railways for facilitating and controlling the ascent and descent of locomotive engines and trains on inclined planes of lines of railway, and for simplifying the construction of locomotives used on railways.* Dated July 25, 1862.

This consists, 1, in dispensing with nearly all the mechanism at present employed, and further in employing only one steam cylinder instead of two, and in fixing the said cylinder to the side framing of the locomotive midway between the driving wheels of the engine. It is also proposed by this invention to employ a rotating piston, and to fix driving cranks in opposite ends of a shaft, to which the said piston is fixed, the said cranks to be connected each to a rod for coupling the wheels together, and imparting rotatory motion direct thereto as the piston rotates. Another improvement, according to this invention, relates to the wheels thereof, and consists in adapting thereto and across the face thereof bars of metal, capable of sliding so as to bring each end thereof successively into contact with an auxiliary wooden or iron rail fixed outside of the permanent iron rails, and at a short distance therefrom, at all the inclined parts of the line of railway, for preventing the skidding of the driving wheels of the engine whilst ascending inclines, and to retard and regulate the motion of the engine whilst descending inclines. *Patent abandoned.*

2118. E. Comfort. *Improvements in watch protectors.* Dated July 25, 1862.

In carrying out this invention the inventor proposes to attach a loose ring to a small metallic compound ring and bar; the loose ring is allowed to enter the waistcoat through a small opening in the lining, and the bar remains behind and outside the pocket. The watch-chain or guard is to be passed through the loose ring, and the other end is to be placed round the neck or through the button hole of the vest. When an endeavour is made to withdraw the watch, by pulling the chain or guard, the bow of the watch is dragged against the ring, and, consequently, prevented from being drawn any further. The wearer, however, by taking hold of the bow of the watch, can always withdraw it. *Patent abandoned.*

2119. A. Lahousse. *An improved construction of railway wheel.* Dated July 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

2120. E. Tysall. *An improved manufacture of fork.* Dated July 25, 1862.

The object of this invention is to construct dinner and dessert forks, so that, without producing any material change in the appearance of such forks, they will, when in use, be enabled to carry up to the mouth together with the viands, a supply of gravy, sauce, &c. The prongs are made of the usual proportions, and of such configuration that, when looking at the back of the fork, it will present the usual appearance. The inner faces (or front) of the prongs are indented with channels or grooves, which increase in depth from the point upwards, until they are stopped at or near the roots of the prongs. These grooved prongs, while the fork is used for carrying food to the mouth, act as narrow scoops for taking up any liquid matters that may be applied to the viands. *Patent completed.*

2121. T. Pagar and J. Rocliff. *Improvements in moulding.* Dated July 26, 1862.

This is applicable to that description of moulding known as plate moulding, and consists in certain improvements in the mode of constructing the parting plates for producing the moulds requisite in casting iron, brass, and other moulds. The invention is not described apart from the drawings. *Patent completed.*

2122. A. V. Newton. *An improved mode of attaching armour plates to ships.* (A communication.) Dated July 25, 1862.

Here the ships' hull is covered to any desired extent with their plates secured by screws, and so arranged as to leave channels between their edges. Over these are laid, so as to break joint, other plates which are applied plate by plate, and kept apart by temporary backing pieces from the first skin of armour plates. Between the inner and outer plates fusible metal is run, so as to form a slightly yielding backing, which metal also fills the space between the edges of the first skin of armour plates. The edges of the overlying lines of plates as they are applied, are kept apart by temporary filling pieces, and these spaces are closed by strips of metal secured in position by clamping nuts. The fusible metal is then run in between the inner and outer layers of plates, and the plates are thus held firmly in position. The metal strips for confining the metal may then be struck off. The above process is repeated as often as required, until the desired thickness is obtained. *Patent abandoned.*

2123. W. Clark. *Improvements in obtaining or extracting silvers from ores and other bodies, and in apparatus for the same.* (A communication.) Dated July 26, 1862.

This consists in the extraction of silver from the extraneous matters in which it is found by certain processes, which are distinguished by the substitution of ammonia, or other bodies, suitable as solvents of the argentiferous compounds, instead of the mercury usually employed. *Patent abandoned.*

2124. J. H. Selwyn. *Improvements in apparatus employed in paying out and raising electric telegraph cables.* Dated July 26, 1862.

Here a buoy is used, which is kept at a distance from the machinery or apparatus employed for paying out or raising the telegraph cable. From this buoy the apparatus is suspended, so as to hang at a distance below the surface of the water. The apparatus consists of certain grooved pulleys, so arranged as to hold the cable and prevent the end from sinking in the event of breakage. *Patent completed.*

2125. T. Long. *Improvements in the manufacture of open metal works, applicable to various useful purposes.* Dated July 26, 1862.

This consists in making a number of slits in a flat sheet of metal, such slits being made in straight or curved lines or rows; the slits in each line or row being made to break joint with the adjoining lines or rows, a smaller portion of the metal being left uncut between the ends of the several slits. The sheet is now stretched out so as to open the slits. The edges of the sheet are turned up, and a length of wire inserted therein. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated Oct. 15, 1862.

2783. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in refrigerating and freezing, and in apparatus employed therein. (A communication.)

Dated Dec. 12, 1862.

3329. J. E. Roussel, 15, Passage des Petites Ecuries, Paris, merchant. Improvements in hand and power looms for weaving. (A communication.)

Dated Dec. 16, 1862.

3363. R. Schomburg, Onslow-terrace, and A. Baldamus, Surrey-terrace, Lorrimore-road. Improvements applicable to all kinds of oils used for illuminating purposes, whereby combustion thereof is rendered more perfect, smoke prevented, and the purity of the light increased.

Dated Dec. 20, 1862.

3403. F. W. Harvey, High-street, Putney. Improvements in fitting and connecting rudders to ships and other floating vessels.

Dated Jan. 10, 1863.

89. L. H. E. Lepreux, Bordeaux. Improved plates or slabs for preserving apartments from the effect of damp, and which are also applicable in the composition of plinths and foundations for walls. (A communication.)

Dated Jan. 12, 1863.

95. W. Clark, 53, Chancery-lane, engineer. Improvements in winding or copping frames. (A communication.)

Dated Jan. 15, 1863.

137. J. P. Bath, Aigburth, near Liverpool, coach proprietor. Improvements applicable to omnibuses and other like carriages, to adapt them for use on rail or tram roads, as well as common highways.

Dated Jan. 20, 1863.

166. A. Paul, Gwennap, Cornwall. Improvements in obtaining reciprocating motion in steam-engines, and for communicating the same to any ordinary pumps, for whatever purpose they may be employed.

171. H. A. Bonneville, 24, Rue de Mont Thabour, Paris. Improvements in colouring, bronzing, and preserving iron and steel. (A communication.)

173. W. Clark, 53, Chancery-lane, engineer. Improvements in looms for weaving textile fabrics. (A communication.)

174. J. Smith, Barkeley House, Seaforth, near Liverpool, and S. A. Chease, Egremont, near Birkenhead. A new description of motive power engine.

Dated Jan. 21, 1863.

181. J. M. Kirk, Halifax and Bradford, dyer and finisher. An improved method of and means or apparatus for finishing textile fabrics.

183. J. Holt, Oldham, machinist. Improvements in willowing and opening cotton and other fibrous substances.

185. W. Clark, 53, Chancery-lane, engineer. Improvements in preparing and obtaining photogenic pictures or representations. (A communication.)

187. E. Bazin, Angers, France, engineer. An improved log.

189. Sir C. Lindsay, 11, Grosvenor-square. Improvements in apparatus to be used on railways to indicate to the engine-driver of a carriage train the length of time which has intervened since the passing of a previous train.

191. N. Clayton and J. Shuttleworth, Lincoln. Improvements in rotatory screens suitable for screening wheat and other grain or seed.

193. H. Holcroft, Rue de la Grandière, Tours, France, civil engineer. Improved machinery for separating substances of different specific gravities.

195. J. C. Brandès, 24, Rue Dunkerque, Paris. An improved hair creaser or divider.

Dated Jan. 22, 1863.

197. J. Ellacot, Liverpool, surveyor. Improvements applicable to spur wheels, racks, and other toothed gear, to insure greater strength in the teeth.

199. R. Penney, Carrbrook, colour mixer. An improved solution or mixture for "fixing" certain colours employed in printing calico and other fabrics.

201. W. Clark, 53, Chancery-lane, engineer. An improvement in piston valves and other pistons. (A communication.)

203. T. Lambert, Short-street, Lambeth, hydraulic engineer. Improvements in apparatus for drawing off water or other fluids.

205. F. W. Morley, Bedford, engineer. Improvements in boilers for steam-engines, and in valves to be used therewith.

Dated Jan. 23, 1863.

207. A. Henderson, Dundee, spinner. Improvements in the preparation or manufacture of textile materials, and in the machinery or apparatus used therein.

209. C. Stopford, Bristol, hat and cap manufacturer. Improvements in the construction of hats and other coverings for the head.

210. F. N. Gisborne, 3, Adelaide-place, London-bridge, engineer. Improvements in the means of communicating signals on board ship, and of indicating the position of the rudder.

211. W. Clark, 53, Chancery-lane, engineer. Improvements in mariners' compasses. (A communication.)

213. C. Turner, Airedale Felt Mills, Hunslet. Improvements in the manufacture of felted fabrics.

Dated Jan. 24, 1863.

215. A. O. Glossop, Sheffield, silversmith. Certain improvements in the construction and manufacture of breakfast cruet and liquor frames used in dinner and other services.

217. W. Allen, Cheadle, cotton spinner, and W. Johnson, Newton Moor, manager. Certain improvements in machinery or apparatus for grinding or pointing the "cards" employed in carding engines.

219. E. and G. Booth, Gorton, near Manchester, gum and chemical manufacturers, and A. Swallow, Staleybridge, colour mixer. Certain improvements in the mode of fixing colouring matter on cotton, silk, wool, and other fibres and materials, and certain improvements in finishing such like and other textile fabrics and yarns.

221. W. Clark, 53, Chancery-lane, engineer. Improvements in syphons applied to draining, irrigation, and other purposes, whereby they self-suspend and resume action according to requirements. (A communication.)

223. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in the manufacture of anvils and other metal articles requiring hard surfaces. (A communication.)

225. F. Tolhausen, 17, Faubourg Moutmatre, Paris. Improvements in machines for carding fibrous materials. (A communication.)

Dated Jan. 26, 1863.

226. W. F. Stanley, 3, Great Turnstile, mathematical instrument maker. Improvements in mathematical drawing instruments.

229. J. Fyfe, Greenock, valve maker. Improvements in safety apparatus for steam-boilers.

231. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in petticoats or crinolines. (A communication.)

Dated Jan. 27, 1863.

232. H. H. Henson, 13, Parliament-street, Westminster, engineer. Improvements in fabrics for covering floors, walls, roofs, and other surfaces or objects, which fabrics are also partly applicable to the manufacture of waterproof articles.

233. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in preserving provisions, and in the apparatus employed for such purpose. (A communication.)

235. C. F. Ash, 20 and 21, Upper Thames-street, iron merchant. Improvements in the manufacture of cornices, joints, and laths of bedsteads, and other articles of furniture.

237. W. Rollason, Birmingham, manufacturer. Improvements in the manufacture of metallic boxes.

239. J. Edmonson, Frizinghall, near Bradford, York, manufacturer, and T. Ingram, Bradford. Improvements in looms and apparatus for weaving.

240. T. Gordon, 41, King-street, Soho. An improved method of, and apparatus for, damping and affixing postage stamps to letters.

241. D. E. Hughes, Gresham House, Old Broad-street, electrical engineer. Improvements in means or apparatus for effecting telegraphic communications.

Dated Jan. 28, 1863.

243. H. B. Barlow, Manchester. Improvements in preserving timber, and in apparatus employed therein. (A communication.)

245. T. Parkinson, Bury, cotton spinner. Improvements in carding engines.

247. E. F. Prentiss, Birkenhead, manufacturing chemist, and J. C. Sellars, chemist. Improvements in treating rock oil, petroleum, paraffin, and other like mineral oils, and products therefrom.

249. H. O. Cook, late lieutenant Indian navy, and E. G. Terrey, 12, Lower Clifton-street, Finsbury. Improvements in propelling ships and vessels, and in apparatus employed therein.

251. R. Ward, Newcastle-on-Tyne. Improvements in locking-up or fastening forms of type or other printing surfaces.

253. J. Platt, 10, Charlotte-street, engineer. Improvements in rotatory engine.

257. J. H. Johnson, 47, Lincoln's Inn-fields, gentleman. Improvements in the manufacture of braid, and in machinery or apparatus employed therein. (A communication.)

259. E. G. Muntz, Birmingham, manufacturer. Improvements in securing axles and axle boxes.

Dated Jan. 29, 1863.

276. F. G. Stuber, teacher, 1, St. James's-road, Brixton. Improvements in the construction of air-tight boxes, cases, cupboards, and similar vessels.

Dated Jan. 30, 1863.

278. W. E. Gedge, 11, Wellington-street, Strand. Improved apparatus for cleansing chimneys or other flues. (A communication.)

280. J. Cocker, Liverpool, gentleman. An improved turnstile especially applicable to omnibuses and other vehicles to show or indicate the number of passengers that have been carried.

282. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in the couplings for railway carriages. (A communication.)

Dated Jan. 31, 1863.

284. M. Smith, Heywood, machine maker. Certain improvements in looms for weaving.

286. T. Bennett, Worcester, photographic artist. Improved arrangements for obtaining pictorial back-grounds, fore-grounds, and perspectives when taking photographic portraits or sun pictures.

288. F. Tolhausen, 17, Faubourg Montmartre, Paris, civil engineer. New or improved apparatus for cleaning the beams of mules and spinning frames, collecting the dust and waste thereof, and also for cleaning the flooring underneath the mule carriages. (A communication.)

Dated Feb. 2, 1862.

292. F. G. Grice, West Bromwich, manufacturer. Improvements in machinery for the manufacture of bolts, spikes, rivets, and screw blanks.

296. W. C. Barnes, Royal Small Arms Factory, Enfield. Improvements in means or apparatus for shaping, rolling, or compressing metal.

Dated Feb. 3, 1863.

300. C. Smithies, Manchester, commission agent, and G. L. Smithies, clerk. Certain improvements in preparing and bleaching "rheea," and other fibrous materials and fibres, which improvements are also applicable to bleaching yarns or piece goods.

302. G. Holcroft, Manchester, consulting engineer. Improvements in preparing cotton for the operations of spinning and weaving.

304. J. Fletcher, Droylesden, near Manchester, engineer, and H. Bower, Halifax. An improved injector or apparatus for feeding boilers with water.

306. T. L. Jacobs, Burton-on-Trent, cooper. An improved mode of, and apparatus for, cleaning casks.

308. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in reflectors. (A communication.)

Dated Feb. 4, 1863.

310. J. Mellor, Ardwick Chemical Works, Manchester, manufacturing chemist. Improvements in apparatus to be used in distilling, subliming, and drying.

312. T. Bradford, Cathedral-steps, Manchester, washing machine manufacturer. Improvements in machinery or apparatus for washing, wringing, and mangling clothes or other textile fabrics.

314. G. T. Bousfield, Loughborough-park, Brixton. Improvements in postage revenue, and other stamps, and in

apparatus for post marking and cancelling postage and other stamps. (A communication.)

Dated Feb. 5, 1863.

324. J. Gill, bleacher, Far Headingley, near Leeds, and J. Parkin, manager. Improvements in apparatus for polishing yarn, twine, threads, and other similar materials.

326. H. Dircks, Blackheath, civil engineer, and J. H. Pepper, 309, Regent-street, professor of chemistry. Improvements in apparatus to be used in the exhibition of dramatic and other like performance.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the *London Gazette*, Feb. 17, 1863.

2678. J. and W. Lee. Traction engines and boilers.

2698. J. Newnam. Crystallizing, and for evaporating.

2710. H. D. P. Cunningham. Working the guns, and in performing necessary work on board ships, and in apparatus employed therein.

2711. J. K. Hampshire. Apparatus or machinery for washing coal, coal slack, and other mineral substances.

2712. J. and M. A. Beale. Preparation or manufacture of manure.

2714. C. F. Terry. Propelling vessels.

2728. A. V. Newton. Breaking and cleaning fibrous substances. (A communication.)

2731. L. Hosch. Constructing travelling trunks and ortmanteaus.

2733. R. E. Green and J. Cockcroft. Amalgamation of materials.

2739. E. Weallens. Surface condensers.

2741. J. J. Shedlock. Gas-meters.

2743. A. Vennedy. Composition for covering and forming the tips of umbrellas and pararols.

2744. R. A. Brooman. Breech-loading firearms. (A communication.)

2747. T. Bouch. Charging or filling cartridges.

2752. A. F. Gallis. Covering street omnibuses.

2755. W. Loeder. Projectile to be used with ordnance or firearms of any calibre. (A communication.)

2770. R. A. Brooman. Carburetting gas. (A communication.)

2779. J. Taylor. Temples for looms.

2781. C. de Bergue. Permanent way.

2783. P. Potenza. Extraction, preparation, and spinning of the silky fibre contained in the bark of mulberry trees.

2787. R. A. Brooman. Felting machines. (A communication.)

2789. R. A. Brooman. Refrigerating and freezing. (A communication)

2797. E. Humphreys. Steering apparatus.

2708. H. Ransford. Building ships and other vessels.

2802. E. Nelson. Heating and superheating steam and air without decomposition.

2808. J. H. Johnson. Prevention or removal of incrustation. (A communication.)

2810. E. Lord. Opening and cleaning fibrous substances.

2816. W. E. Gedge. Extracting condensed steam. (A communication.)

2817. W. Clark. Dredging. (A communication.)

2844. E. Fielding. Manufacture of healds.

2846. H. H. and J. F. G. Kromschroeder. Manufacture of gas-metres.

2905. J. Jeffreys. Heating and cooling fluids.

2907. A. Ripley. Pistons.

2209. G. Darlington. Manufacture of zinc oxide.

2913. W. Clark. Treatment of copper ores. (A communication.)

2946. G. Speight. Manufacture of collars.

2965. L. Gonez. Seat or chair.

3155. W. Tatham. Preparing and spinning fibrous materials.

3366. W. Tongue. Preparing fibrous materials.

160. Sir W. O'S. Brooke. Insulators

191. N. Clayton and J. Shuttleworth. Rotary screens, screening grain or seed.

196. J. Grant. Construction of sidings and loop lines for railways or tramways.

199. R. Penny. Fixing certain colours.

217. W. Allen and W. Johnson. Grinding or pointing cards employed in carding engines.

220. M. A. F. Mennons. Punching and cutting metals. (A communication.)

233. G. Davies. Preserving provisions. (A communication.)

270. N. Clayton and J. Shuttleworth, Thrashing machines.

300. C. and G. L. Smithies. Preparing and bleaching fibrous materials and fibres.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed Feb. 13, 1863.

2299. J. Barclay.
2311. S. A. Bell and T. Higgins.
2315. J. T. Oakley.
2321. V. F. Clenet.
2323. S. Boucher.
2326. J. G. Tongue.
2327. W. Whittle.
2331. J. Standish and J. Gooden.
2335. J. C. Schoenmann.
2341. S. F. Griffin.
2357, M. K, Angelo,
2361. M. J. Haines.
2398. F. H. Lefranc.
2436. F. C. Bakewell.
2455. J. S. Margetson.
2467. W. A. Richards.
2513. J. Thom.
2530. W. G. Rawbone.
2655. J. Wright.
2768. D. R. and C. J. Reid.
2245. M. C. de C. Sinibaldi.

Sealed Feb. 17, 1863.

The *Art Journal* of November, in its description of Benson's Great Clock, says:—"It has attracted universal attention; its construction has, we believe, obtained general and strong approval; it is one of the largest chiming clocks as yet manufactured in this country." Benson's new show rooms contain clocks designed by the first artists of the day, and include clocks for the drawing-room, dining-room, bed-room, library, hall, staircase, bracket, carriage, church, turret, railways, warehouse, counting-house, with musical, astronomical, and every description of clock, from the plainest to the highest quality of which the art is at present capable. Church and turret clocks specially estimated for. Benson's illustrated pamphlet on clocks and watches (free by post for two stamps) contains a short history of clock and watch making, with descriptions and prices; it acts as a guide in the purchase of a clock or watch, and enables those who live in Scotland, Ireland, Wales, the Colonies, India, or any other part of the world, to select a clock. J. W. Benson received a Prize Medal and honourable mention.—33 and 34, Ludgate-hill. Established 1749.

LONDON, FRIDAY, FEBRUARY 27, 1863.

WROUGHT-IRON DIRECT FROM THE ORE.

AMONG the multitude of problems awaiting the solution of practical and scientific men is that of the production—with commercial advantage—of wrought-iron direct from the ore. We are aware that some attention has been given to the subject in this country, and that experiments to a limited extent have been made in several of the iron districts, with a view to accomplishing the desideratum. Hitherto, however, no amount of success worthy of record has been achieved, and the complicated and expensive processes of fusion in blast furnaces, refining, and puddling, are almost universally resorted to for the production of malleable iron. The fact exists, nevertheless, that much of the bar iron imported into England from abroad, is the result of direct conversion from the ore. It seems incredible that with infinitely greater advantages both in respect to abundance of fuel and variety of ores, we should lag behind in this important department of iron manufacture. Surely if persevering and well-judged efforts were made, the stigma of inferiority might be removed, and another branch might be added to the flourishing iron manufacture of Great Britain. Theory at least is in favour of direct conversion from the ore, and there is little reason to doubt that practice will eventually confirm the theory. At any rate it will be satisfactory to set the question at rest, and this can only be done by conducting experiments on a much more varied and extended scale than has yet been ventured upon. The probability is that in most of the attempts hitherto made for the accomplishment of the object, too much attention has been directed to what *has been* previously done, and too little to what *may be* effected. It is, indeed, too often the case that in the pursuit of scientific discovery the explorer is hampered by the teachings of predecessors rather than expedited by the conception of original ideas. There unfortunately exists in most minds a predisposition to move forward through the same grooves which have been opened up by others, and hence too often the same goal of failure and discouragement is reached. What is wanted is, as we have said, more originality of action, more working out of one's own thoughts, and less of slavish conformity to the dogmas and dicta of others. When these points shall be attained, the progress of discovery will be far more rapid than at present, and the world will benefit largely by the change.

Let those, therefore, who may be induced to embark in the enterprise of endeavouring to solve the question which has suggested the foregoing remarks, dismiss as far as possible from their minds the theories and peculiar modes of operation held and adopted by former labourers in the same field, and act out, as it were, their own convictions and experiences.

Not directly as a guide to the achievement of success, but rather as a beacon to warn them off the rocks of failure and disappointment, shall we now, therefore, briefly call the notice of our readers to the means heretofore employed in the production of wrought-iron immediately from the ore.

It is the ordinary practice to deal with ores intended for conversion as follows:—The raw material is first ground to a coarse powder, and then, in conjunction with a quantity of carbonaceous matter, similarly treated, it is charged into a reverberatory furnace, somewhat resembling an ordinary puddling furnace. The draught is forced to the production of a high temperature, thus reducing the ore to a semi-liquid state. By dexterous manipulation on the part of the attendant operative, metallic iron is separated from the extraneous matter, balled up, and shingled. The theory of this operation is simple. The carbon of the carbonaceous matter is consumed by uniting with the oxygen of the ore, and the metal is left free to agglutinate into a mass. The Beaufort black band ore was thus converted into malleable iron, though after a few experimental trials the operation was discontinued. The principal objection to its extensive adoption seems to lie in the difficulty of effecting a complete separation of the extraneous metalloids of the ore. In the blast furnace it is accomplished by mechanical subsidation in the hearth, and the extraction of the metallic iron from the low level. In the direct mode of manufacturing it is effected, to a certain degree, by severe manual labour, which, however, being skilled, commands a comparatively high price, and materially enhances the expense incident to the process.

The prolonged exposure of the metallic iron to the oxydising influence of the flame and gases, during the process of separation from the alloyed matters, results in a considerable waste of metal, and accounts for the comparatively inferior yields. To obviate this loss, and to economise the fuel and labour demanded, the ground ore and carbonaceous matter have (in some cases) been subjected to the necessary heat in a closed supplementary chamber, whereby the combustion of the carbon is slowly carried on at the expense of the oxygen of the ore, but at a sufficiently low temperature to avoid oxydizing the mass. From this chamber it is drawn as required into the furnace, balled up, and shingled, the deoxydized ore agglutinating without undergoing the puddling process, which, being essentially of a decarburizing character, is unnecessary with the minimum volume of carbon consumed in the deoxydation of the ore in the close chamber. Ground carbonaceous ore may be substituted for the carbonaceous matter, and mixed in the necessary proportions with the same ore calcined, or, with raw hematite, the deoxydation can then be effected without the usual ground coal, and at a considerable reduction of expense.

In this respect, as has been said, the possession of ores of such varied kinds as we have, gives the British iron-master an important advantage over his foreign rival. Possibly at some future day, and Truran, in his admirable work on Iron Manufactures, advances that opinion—this mode of manufacture may be more extensively and profitably adopted. The rich carbonaceous ores of Scotland or of Wales, mixed with the hematites of Lancashire or West Cumberland, or other similar ores, reduced in suitably-constructed furnaces, may be converted directly into malleable iron, at costs considerably under those incurred with the blast furnace and subsequent decarburizing system.

With existing modes of operation, the advantages of direct conversion are principally confined to the small amount of capital required to establish the manufacture, which, though conducted on the smallest scale, may yet be comparatively profitable. In new districts requiring an immediate small supply, and to countries deficient in the capital money for carrying on operations on a large scale, the direct conversion of the ore into wrought-iron is of especial consequence; but we have hopes that at home it will, by-and-bye, be not only extensively practised, but be found correspondingly profitable to those who succeed in effecting it. At all events the subject is one of great interest; and we cannot doubt that those who are connected with the iron manufacture will give to it due consideration, and that practical attention which it deserves.

THE METRIC SYSTEM OF WEIGHTS AND MEASURES.

WE have on several occasions directed public attention to the anomalous and confused arrangements which exist in this country in reference to weights and measures; and it is certainly high time that the Legislature interposed for the purpose of simplifying those arrangements. It is discreditable that, while elsewhere improvements of almost every kind are being affected, in this department ancient usage rather than modern convenience should still reign supreme. The International Decimal Association has done much to clear the way for the introduction of a uniform system of weights and measures, and there can be little doubt that the public would speedily appreciate a change which must economise both time and money. The hour is, indeed, opportune for such a measure of social reform as we have indicated. The struggles of political parties which were wont to distract the attention of our representatives in Parliament from the real business of the nation, are not at present stopping the way, and thus a fair opportunity is afforded for considering deliberately such questions as this. A committee of the House of Commons unanimously reported last session in favour of a metric system of weights and measures, and came to the following detailed and distinct conclusions:—

1. That the use of the metric system be rendered legal, though no compulsory measures should be resorted to until they are sanctioned by the general conviction of the public.

2. That a department of weights and measures be established in connection with the Board of Trade. It would thus become subordinate to the Government and responsible to Parliament. To it should be entrusted the conservation and verification of the standard, the superintendence of inspectors, and the general duties incident to such a department. It should take such measures as may from time to time promote the use and extend the knowledge of the metric system in the departments of Government, and among the people.

3. The Government should sanction the use of the metric system, together with our present one, in the levying of the Customs' duties; thus familiarising it among our merchants and manufacturers, and giving facilities to foreign traders in their dealings with this country. Its use with that of our own system in Government contracts has also been suggested.

4. The metric system should form one of the subjects of examination in the competitive examinations of the civil service.

5. The gram should be used as a weight for foreign letters and books at the Post-office.

6. The Committee of Council on Education should require the metric system to be taught (as might easily be done by means of tables and diagrams) in all schools receiving grants of public money.

7. In the public statistics of the country, quantities should be expressed in terms of the metric system, in juxtaposition with that of our own, as suggested by the International Statistical Congress.

8. In private bills before Parliament the use of the metric system should be allowed.

9. The only weights and measures in use should be the metric and the imperial, until the metric shall have been generally adopted.

10. The proviso in the 5th & 6th William IV., cap. 63, sec. 6, should be repealed.

11. The department which it is proposed to appoint should make an annual report to Parliament.

These propositions are sufficiently explicit; and upon them we are not without hope that an Act of Parliament may, before the present session is passed, be based and carried into effect. At present as many as ten different systems of weights and measures are in use in this country. There is first the grain, computed decimally, which is used for scientific purposes; second, the troy weight, under 5th George IV., cap. 74, and 18th and 19th Victoria, cap. 72; third, the troy ounce, with decimal multiples and divisions, and called bullion weight, under the 16th and 17th Victoria, cap. 29; fourth, banker's weight, to weigh 10, 20, 30, 50, 100 and 200 sovereigns; fifth, apothecary's weight; sixth, diamond weight and pearl weight, including carats; seventh, avoirdupois weight, under 5th George IV., cap. 74, and 18th and 19th Victoria, cap. 6, sect. 72; eighth, weights for hay and straw; ninth, wool weight, using, as factors, 2, 3, 7, 13, and their multiples; and tenth, coal weight, decimal, under 1st and 2nd William IV., cap. 76, and 8th and 9th Victoria, cap. 101. We have also in occasional use the weights of the metric system. For measures of length we have the ordinary inch, foot, and yard. In cloth measure we have yards, nails, and ells. There are four different sorts of ells. For nautical purposes we have fathoms, knots, leagues, and geographical miles differing from the common mile. The fathom of a man-of-war is 6 feet; of a merchant vessel 5½ feet; and of a fishing smack 5 feet. There are also the Scotch and Irish mile, and the Scotch and Irish acre. We have in the United Kingdom several sorts of acres, and a great variety of roods. In almost every trade there are in use trade measures, specially employed in those trades. For the measurement of horses we have the hand; shoemakers use sizes; and we are compelled to use gauges where the French use the millimetre. The gauges are entirely arbitrary. The custom of the trade is the only means of deciding questions in dispute.

For measures of capacity there are twenty different bushels. Few can tell what the hogshead means. For ale it is 54 gallons; for wine it is 63 gallons. Pipes of wine vary in many ways; each sort of wine claims the privilege of a different sort of pipe. For measures of weight there are ten different stones; a stone of wool at Darlington is 18 lb.; a stone of flax at Downpatrick is 14 lb.; a stone of flax at at Belfast is 16¾ lb., but it is at the same place 24½ lb. The cwt. may mean 100 lb., 112 lb,, or 120 lb. If you buy an ounce or a pound of anything, you must inquire whether it belongs to Dutch, troy, or avoirdupois weight.

Such are some of the absurd arrangements which at present obtain in this country, the centre of commercial industry, and the heart of civilization. Mr. Leone Levi, who has taken much pains to inquire into these anomalies, is of opinion that the foregoing are but a portion of those which really exist. How necessary, therefore, is a revision and simplification of the conflicting systems! Surely they ought to be swept away *in toto*, and a simple and intelligible plan established in their lace!

We believe that a bill will actually be introduced into Parliament before long for effecting this desirable object; and we sincerely trust that the Government will have sufficient judgment to adopt it, and the two Houses decision enough to carry it through. Uniformity of weights and measures once fairly established, we might also hope for the introduction, at no distant period, of a Decimal system of coinage, which in itself would be a boon of incalculable value.

ROADS AND TRACTION-ENGINES.

There are some 22,000 miles of *turnpike* road in England and Wales, while a large sum is annually spent in keeping these highways in a passable state of repair. How shall we bring this great length of road under the dominion of King Steam? Ought we to lay down lines of rails at the rate of at least £5,000 to £10,000 per mile; or should we at once use traction-engines? However much the meshes of the great railway net spread over England are getting narrowed by the requirements of an extending communication, the map of the country still shows a comparatively small amount of railway mileage. The use of rails on a road trodden by horses and vehicles, has great practical difficulties in its wake; although, on the other hand, the mechanical economy of traction power undoubtedly requires an unyielding surface for the wheels. But it would cost an enormous sum to apply rails to ordinary roads, even if a line of rails did not clash with the requirements of highways, necessarily open to all descriptions of conveyances. Besides, unyielding surfaces in the shape of rails, cannot be carried up to every man's door. A steam link of communication, of more adaptability than a line of rails can ever be, will never cease to be a desideratum; and a system of traction, taking an intermediate position between railways and highways, will always be required. How would it be possible to have lines of rails along the narrow country lanes? The steam carthorse consumes only cheap coal; while animal muscles must be renewed with expensive hay and oats. Rails cannot well be put down in fields that have to be annually ploughed up. A system of steam cultivation has been certainly proposed, upon the basis of a connected system of rails laid down throughout the country. But this *mechanical* system would, probably, require a revolution in the whole *political* system to carry the plan out. We cannot wait for this. The great advantage of a traction-engines over a system of rails is, that traction-engines can be applied at once over the whole extent of the existing roads.

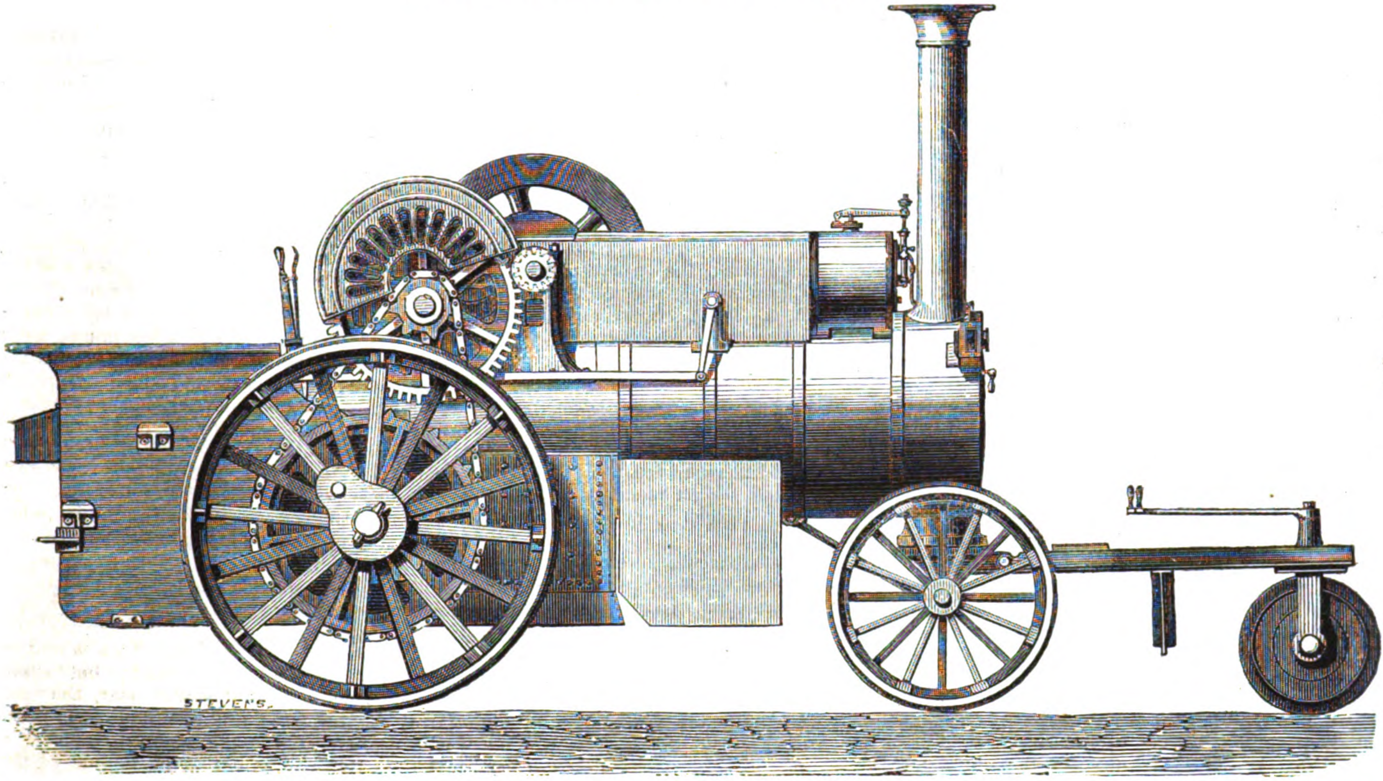
It has been feared that traction-engines will exert a destructive influence on the roads. No doubt this is the case to some extent. It is, however, well known to experienced road surveyors, that great injury to macadamised roads is caused by the hoofs of the horses. The relative damage done by the hoofs of horses in fast carriages, compared with that caused by the wheels, is about 3 to 1. Besides, the more traffic, the more tolls; while it is not improbable that improvements may be brought to bear on road surfaces, increasing their adaptability to the driving wheel of a traction-engine. It thus appears to us that the problem of an uninterrupted steam communication would be solved by gradually extending the present lines of rails, and in the mean time to communicate with the termini by means of steam traction-engines.

A great impetus has been given to the development of the self-propelling engine, by the extensive, and still extending, use of steam on the farm. The *direct* system of steam cultivation almost absolutely requires a traction-engine. It has been well observed that the sight of half-a-dozen horses dragging at a so-called *portable* engine, is an insult to mechanical science. The engine could exert perhaps ten times the power of the horses dragging it to its destination. Men whose business consists in hiring out portable steam-engines in the farming districts, must greatly feel the want of a self-propelling engine.

In many parts of the world; in South America, in Australia, and even in some parts of the Continent, there are valuable mines of copper, silver, etc., lying in the interior of the country, and situated hundreds of miles from a seaport. It would never pay to lay down a line of rails for the sake of a few mines, however valuable the property might be. On the other hand, centuries would elapse before the population could be dense enough to render a railway profitable. The great drawback to these mining undertakings has been the enormous expense of carrying the ore to the commencement of the water communication. At the same time, wood is plentiful, as it generally is in uninhabited districts. There is thus no want of fuel, and the abundant supply of wood is also generally used to form what the Americans call a "corduroy road," which consits of logs about a foot in diameter, laid side by side as close as possible. This would be an expensive road in England; but where wood is cheap, and labour is dear, the contrary is the case; and corduroy roads adapt themselves admirably to the requirements of the traction-engine. A good engine of this description is thus a mechanical necessity of the day. Most of the aspirations and wants of our time were more or less completely represented in the Great Show at Kensington. Accordingly, about nine of these engines were exhibited in the eastern annex of the International Exhibition. Several were crude and undeveloped specimens, exhibiting the weakness of some of the engine makers when treading on comparatively unbeaten ground—shall we say *track?*

The traction-engine that was perhaps the most admired by good judges for its combined simplicity and efficiency, and for its low prime cost, the usual accompaniment of simplicity, was the "exhibit" of Mr. Aveling, of Rochester. Its construction was a happy marriage of ingenuity with common sense. A nearly identical engine to the one in the Exhibition was also at work at the Battersea Agricultural Show of last year. The engine in the Exhibition weighed 8 tons empty, and about 10 tons when full. The cylinder was 10 inches in diameter, and 12-inch stroke. The fire-box was of Bowling iron, with stay-bolts pitched 5 inches from centre to centre. The boiler was flush from end to end. A pair of longitudinal stays placed below the tubes were made to connect the two tube plates. The fire-box was lagged, and the engine was counter-weighted. The driving wheels could be easily disconnected from each other, and from the propelling gear, by taking out a pin uniting the boss of the wheel with another boss on the axle; this is for easily turning round corners. There was a powerful friction break on the driving axle, in case of need when descending an incline. There was no steam dome, properly so called, on the boiler, but the cylinder was surrounded by a lagged metal jacket. This steam chamber is brought into direct communication with the steam by means of holes made in the top of the boiler, the cylinder being bolted thereon. The steam thus circulates constantly round the cylinder, and

AVELING AND PORTER'S PATENT TRACTION ENGINE.



there is no necessity for a steam pipe. The cylinder being placed close up to the chimney, the exhaust pipe is thereby very short, with its attending advantage of a small back pressure.

There will be little tendency to prime in this engine, as the cylinder is placed as far as possible from the fire-box, the place where the water is most agitated by the ebullition; the steam is dried by the dome-like properties of the peculiar construction of cylinder; and on ascending inclines, the cylinder is necessarily fed with dry steam. The steering apparatus is very simple; it consists of a single steering and carrying wheel, made to swivel on its supporting rod at the end of a light wrought-iron frame fitted to the front end of the smoke-box. A man sits in front of the engine, guiding the wheel in his hand, and the massive traction-engine behind is literally "led by the nose" by means of this simple steering gear. The self-propelling gear consists of a pinion on a feather at the end of the crank-axle, and working into a larger wheel on a stud below; on this wheel is cast a pinion with chilled teeth, to take in a pitch chain, made of massive iron links and steel pins. In the bracket carrying the axis of the drum, there is a curved slot in which the block for the stud of the small chain wheel can be made to slide. The curve of this slot is struck from the centre of the main driving-shaft above. The spur wheel thus always remains in gear with the driving pinion on the crank shaft. These were some of the peculiarities of the engine in the Exhibition. One of its most important features was the excellent construction of fire-box and boiler, enabling it to raise the high pressure of steam for exerting the great power required from a traction-engine.

By the courtesy of Mr. Aveling, we were lately enabled to see the performance of one of his peculiar traction-engines. The engine tried was one of the several now being manufactured at the Rochester Works for the Yudanamutana Copper and Mining Company, South Australia. The mines of the company are about 120 miles from Port Royal, and the ore has to be transported all this distance over an unbeaten track of ground. The traction-engines have to run ten miles at a stretch; there being water stations at every tenth mile. We believe that Messrs. Aveling and Porter are also making the fixed plant for the stations. The cost of carriage is said to be nearly £10 per ton, but as the fuel (wood) is cheap and plentiful, the traction-engines will probably reduce the freight to £2 per ton. In its main features the engine was similar to the one in the Exhibition, but it embodied several improvements and additions. The engine tried weighs, empty, 11 tons, and about 13 tons in working trim. The fire-box is 40 in. long, 31 in. wide, and 20 in. deep inside. The fire-box stay bolts are 4½ in. from centre to centre. The boiler is 3 ft. 1 in. in diameter inside, containing 37 lap welded tubes, 2¼ in. in diameter outside, and 5 ft. 7 in. long; the barrel and outer fire-box being of ⅜ plates, from Earl Dudley's Works; the inside fire-box is of the same thickness of plate; the fire-box tube plate and the door plate are ½ in. thick. The smoke-box tube plate is a round disc ⅝ thick, rivetted within the smoke-box; being flanged all round. The barrel of the boiler has butt-riveted joints and straps, and there are two longitudinal stays in the boiler barrel. The whole boiler is flush, and without any angle iron. The fire box is carefully lagged. The construction of the entire boiler seems to come up to the best standard of locomotive work, and is thus enabled to use the locomotive steam pressures of 100 to 120 lbs. in the square inch. The cylinder is 10 in. diameter and 12 in. stroke, like the cylinder of the Exhibition engine; it is cast from the same pattern, and arranged on a similar plan. On investigation, no inconvenience appeared to arise from their being only one cylinder, as the driver could easily take the engine off the dead points by turning the multiplying gearing at the other end. The steering gear is also the same. The working parts are neatly housed in from the influence of the weather. The toothed gearing was also covered with light cast-iron splashers. The chief differences between this engine and the one in the Exhibition consist in the mode of taking up the slack chain, and in the geariug being double, in order to get either two miles or four miles an honr speed of traction-engine.

There is a pinion at each end of the crank shaft; and either of these pinions can be thrown in and out of gear with the spur wheel below by sliding it along a feather on the shaft. The pinions are ingeniously kept in the positions required by means of a simple clip of spring steel, embracing the shaft, and lined with leather; it is quickly slipped off and on the shaft as required. The ratio of gearing obtained by the pinions and plate wheels is 1 to 20 on one side and 1 to 14 on the other. As in the Exhibition engine, the brass bearing carrying the large toothed wheel is fitted in a radial slot struck from the centre of the crank shaft. The adjustment for taking up the slackness of the chain is, however, effected in a different manner. The brass bearing is kept up in the slot by a block at bottom. There is another cast-iron block above, lying on the bearing and kept down by a set-screw. When the bulk of the chain has to be taken up, the thinner block below is taken out, and the thicker one above is substituted in its stead. The brass step is thus fixed in a perfectly firm and solid adjustable bearing. A neat plate covers up the whole.

The driving wheels are 6 ft. 6 in. in diameter, with a cast-iron rim, 18 in. wide, and a cast-iron nave 15 in. diameter. There are fourteen wrought-iron spokes, 2½ by 1 in., cast 3½ in. into the nave, the ends of the spokes being first notched and dipped into tar. The nave is cast one day after the rim, so that the contraction of the rim may not affect the strength of the wheel. The driving wheels of the Exhibition engine had blank spaces on the face, in order to slip T iron paddles or clips on to the wheels when passing over soft and yielding ground. In order to conform with the Locomotives Act, these openings are now filled up with small castings, dove-tailed in, and further fastened by pins. These castings are slipped off, when it is wished to put in the T iron clips. Spikes are also employed to increase the grip of the wheels. The bearings are inside the wheels. The driving axle is of scrap iron, 5 in. in diameter. The axle is fitted in axle plates fixed outside the fire-box, between the latter and the tank behind. Thus, although there is no longitudinal framing, the traction strain on the fire-box is, in a great measure, taken up by the intermediate grip of the wheels on the ground.

The weight is chiefly on the wheels, particularly on steep hills, which somewhat accounts for the remarkable performances of this engine. There are no springs, Mr. Aveling not judging them necessary for the slow speeds at which the engine is intended to work—from two to four miles an hour. There is a blower in the smoke-box. The man-hole is in the smoke-box tube plate. There is a warming cock for heating the water in the tank. The *lower* slide bars are of steel. The chimney is of cast-iron, in one casting ¼ in. thick. The ends, top and bottom, of the water-tank are made of cast flanged plates, the wrought-iron sides being bolted directly thereto. The water tank in front of the fire-box contains 69 gallons of water; the tank behind contains 211 gallons. The tanks carry coal and water for a run of 10 miles. We saw "No. 53" marked on the Yudanamutana engine, which evinces great success in the sale of traction-engines, as we believe that the firm took up this branch of their business only three years ago. The price marked on the engine in the Exhibition was £420. On account of the one tried being made with a larger fire-box, double gearing, additional water-tank, &c., this price has been raised to £530.

The traction-engines now making for South Australia are intended to draw a train of about six waggons. Each waggon is strongly built of oak, and is on four wheels, the front wheels being 3 ft. 6 in., the hind wheels 4 ft, 9 in., in diameter. The front wheels can swivel, and there is a light iron coupling between each waggon. At the late trial of this traction-engine the roads were in a yielding, sloppy state, from the effects of the weather; the mud formed a complete lubricating material between the wheels of the engine and the road. At the same time, to prevent any injury to the road-surface, the clips were not applied to the driving wheels; a few spikes only were inserted in the rims. Each waggon, when loaded with large baulks of timber, weighed about five tons. We saw the engine take five waggons up inclines varying from 1 in 12 to 1 in 8, at speeds varying from four miles to about two miles an hour. The engine ran 7 miles in about 2½ hours, and consumed about 3 cwt. of coal. Probably, no traction-engine, of the same weight, has ever accomplished so much. The engine, with its train of four coupled waggons, passed some very sharp corners with great ease. This is one of the great advantages of an engine over a train of horses, as in turning corners only one or two horses are able to pull properly. The hissing of the steam certainly frightened some horses on the road. This is one of the impediments to the more general introduction of traction-engines. We know, however, by our own experience, that horses very soon get accustomed to the whistling of steam. Of course, if horses can be made to stand the firing of guns, there is no reason why they should not be made to stand the noise caused by a blast pipe.

It is well known that the resistance offered by the surface of a common road to the motion of a vehicle, is in a direct ratio to the load; is in an inverse ratio to the diameter of the wheels; while the resistance is almost uninfluenced by the breadth of the wheels. At slow speeds the resistance is almost independent of the velocity of the vehicle. The co-efficient of resistance, however, varies so much with the state of the road (according to Morin, about from 1-13th to about 1-50th of the load), that it would be scarcely possible to estimate, by calculation, the precise tractive power exerted by Mr. Aveling's engine. Suppose we compare the traction-engine to a team of horses; neglecting the power exerted in moving itself, and only taking into account the four loaded cars. Each car weighed with its load about 5 tons, with wheels averaging 4 ft. in diameter, and 4½ in. in tyres. Considering the bad state of the surface, we may take the co-efficient of resistance on the road at 1-20th of the weight; and the four cars weighing together 20 tons, the resistance on a dead level would thus be 1 ton. To this would be added 2 tons for an incline of 1 in 10, making a total of 3 tons for four waggons, on an incline of 1-10th.

Perhaps the most accurate means of learning the available tractive power would be to use a strong dynomometer, similar to the one employed by Mr. Fowler for ascertaining the draught of his six-furrow steam-plough.

We believe that we may congratulate both Mr. Aveling and his customers on the results of the experiments we lately witnessed.

II.

CONDITION OF OUR IRON CLADS.

One fact is worth a bushel of arguments. We copy, from the Naval Intelligence of the *Times*, an account of the condition of the squadron of iron clads just returned to the Channel, after a cruise in search of gales.

"There are various rumours in circulation as to the actual defects of the squadron. Some are to the effect that the injury done is but trifling either to hulls or machinery, while others assert that although the 'Black Prince' represents the *maximum* of defects in the engineering department, yet all have suffered in their hulls, and especially in the rigidity of their armour plating. The plates are said now, in many instances, to be very loose, a result that might naturally be expected from the way in which they are hung on the ship's side, and the weather the ships have gone through since being commissioned. It is not at all improbable that as other ships can be brought forward the officers and crews of our present iron fleet will be turned over to them, and our four iron ships at present afloat—the pioneers of the future—be laid up in ordinary in readiness for an emergency. There are two reasons, each sufficient in itself, to lead us to believe that this course may be followed. It will certainly be necessary to test our ships that carry armour all round, such as the 'Hector,' 'Royal Oak,' and 'Minotaur,' as fully as we have tested our present partially cased fleet, and we may do this with the officers and crews of our iron-cased fleet at Spithead, The second reason is that we cannot afford, with all our proverbial extravagance in naval matters, to continue experimetal cruises with our iron ships at present afloat in search of gales of wind, without increasing the looseness of the plates and otherwise injuring them. The working consequent upon their looseness would result in a compelled removal of the ship's armour and the employment of new plates; for, of course, no one would pretend to argue for a moment that the same tongued and grooved plates could ever again be placed on a ship's side after being once taken off, especially after such a knocking and buffeting about as Admiral Smart's squadron have undergone."

So at last the truth is out. The inefficiency of the "Warrior" system of armour plating, pointed out in the Mechanics' Magazine more than a year ago, is a fact. An explanation of that system, illustrated by a diagram, which appeared in our columns, described by anticipation the inevitable results of fastening ponderous plates on wood backing with through bolts in the following terms :—"The inherent weakness of this fastening will be perceived. The bolt forms a lever, of which the iron skin is the fulcrum, only half-an-inch in width, and the two arms are, one 22½ in., the other, 3 in. long. The enormous weight outside the skin is suspended to the long arm, and supported by the nut screwed on to the short arm. By this arrangement, there is an immense amount of leverage outside the frame and skin of the ship, tending to tear away the armour plate. The bottom strake of armour plates and teak rests upon the recess, the other strakes rest one upon another, but as the ship rolls and pitches, the ponderous plates at the end of the long bolts have a tendency to fall overboard, and put a violent strain on the nuts and skin. By the constant working of the ship, the bolt holes through the teak will become enlarged, and the bolts themselves will be loosened, causing motion and vibration with every movement of the ship throughout the whole body of iron and wood (weighing about 1,500 tons), which constitute the external armour of the 'Warrior.'"

On several occasions we showed the immense importance of this question, and urged the necessity of decisive trials of a plan theoretically wrong, as well as of other plans submitted to the Admiralty, before completing the armour plating of the ships under construction. We proved by figures, unmistakeably, that the armour of every "Warrior" or "Minotaur," would cost about £100,000, and therefore the iron casing of ten ships of these classes involved an expenditure of a million. In vain did we raise our voice. The subject was little understood. The *Times*, the officials, in and out of Parliament, represented the "Warrior" plan as perfection, and ship after ship was hurried on to completion, without pause or hesitation, as if no better plan could be devised.

We are now warned by the *Times* itself that the day of reckoning is at hand. The danger we pointed out, the possibility of which was pertinaciously ignored, is now admitted to be "a result which might naturally be expected from the way in which the plates are hung on to the ship's side."

Here we have an illustration of the apathy of the Admiralty, and the shifts to which its supporters are driven to bolster up a vicious Administration and delude the public. The *Times*, in the statements it publishes to serve the purpose of the moment, systematically relies upon its readers forgetting one week what they read the last.

At the very moment we are called upon by that journal to admire the economical measures which reduce the navy estimates by a million, we are deliberately told that "no one would pretend to deny" that the armour plates of every one of the iron clads built will have to be taken off and replaced by new ones. Here is a confession to a lamentable want of foresight, and almost criminal disregard to repeated warnings. If the House of Commons does not look to this matter in right down earnest, they will fail in their duty. The ramifications of this now acknowledged failure of the "Warrior" armour are wide spread. It applies still more forcibly to wooden iron clads, jeapordizes the turreted ship, and condemns "wooden bottoms." If the sides of the "Warrior" and "Black Prince," of which the rigidity is immensely increased by the iron skin and frames, are in the condition described after a few days "knocking about," in what state will wooden sides be after a similar ordeal? We have had alarming reports of the leaky state of the "La Gloire," whose armour plates, it was stated, would have to be renewed. In comparison with these much stronger built vessels, we may imagine what will be the effect on the hull and top sides of the "Enterprize;" for instance, when tossed on the waves of a stormy sea, encumbered by the top hamper of her fighting-box, with a light draught, and her ends fore and aft, from the nature of the build, liable to be submerged and swept by the billows. The character of her iron top sides, depending on the insecure fastening together of wood and iron, will be put to the proof. With reference to the resisting force of the armour of the "Enterprise," we hope the Admiralty, after the sad experience it has had of the effects of want of rigidity in the "Warrior" section, will have a target made in order to test the value of 4½ in. plates on 18 in. of wood, without the iron support behind, which gives rigidity to, and is the real source of, strength to the "Warrior" sides.

In the debate on the navy estimates, Mr. Cobden, with his usual felicity of application of practical data, which he candidly acknowledged he derived from the information supplied by men of authority, confirmed the view we have long advocated as to the incongruity of the combination of wood and iron, in the construction of iron clad ships of war. Referring to the high authorities, whose opinions might be relied upon, he used these remarkable words—"They have all emphatically declared that not a "vessel ought to be constructed of wood, cased "with iron, because you are thereby putting a "harder and more rigid substance on a softer "and more flexible one, and the foundation will "give way."

It is impossible to condemn in plainer terms the system of "wooden bottom" construction. Like Mr. Cobden, we do not, in the present state of the question, venture to express a decided opinion of our own. We have no bias; we listen to the advocates of wood and iron, and we admit into our columns the arguments on both sides. At the same time we must confess the conclusion which such a man as Mr. Cobden has come to, after weighing the opposite opinions, makes a deep impression on our mind, and we agree with him, Mr. Laird, and a number of experienced naval men and engineers, that it is the duty of Government to pause in their career of naval construction until experiment and actual experience at sea have determined which is the best class of iron-clads.

Obviously the objections to the construction of a ship with iron plates on a foundation of wooden planks and frames, are applicable to fastening iron armour plates on a wooden backing. The force of those objections is exemplified by the disastrous results to the iron clads in their recent cruise. It would follow, then, from practice, as well as theory, that the true principle of strength for iron-cased vessels is rigidity, which can only be attained, in its highest degree of perfection, by a structure composed wholly of iron. The design of such a structure, fulfilling the conditions of a sea-going and an invulnerable ship, is the problem to be solved by the joint labours of the mechanical engineer and naval architect.

Another fact, and the conclusion drawn from it by the shrewd member for Rochdale, deserve to be recorded as having a direct bearing on a charge against the Admiralty, which has been ventilated in this journal. "My noble friend," says Mr. Cobden, "let out a secret a little while "ago I should not have dreamt of attributing "*motives to him*, if he had not corroborated my "suspicions. But I never could understand "why the Admiralty should buy such an enor- "mous quantity of timber—why they should lay "up a store of 112,000 loads, their whole aver- "age consumption yearly not being a third of "that amount. A friend (says Mr. Cobden) "told me last year, that is all done by the people "in the dockyard; the political officials at the "head of the department know nothing about "it;" and then he continues, "at this moment "they are filling the dockyards with timber, "they are filling the quays also. They are so "full, that I believe the Port Admirals can "hardly walk about. And this very superabun- "dance of timber is then urged as a reason "why they should build iron clads (that is of "wood) in the dockyards, instead of having "*wholly iron* vessels built by contract."

We have been reluctant to place any reliance on the charge of complicity among dockyard officials and the Controller's Department, to entrap the country into a renewal of the construction of a wooden navy; but when we find a member of Parliament, of undoubted prudence and sagacity, plainly insinuating the existence of such a design, we must admit it is not devoid of probability.

Since the above was written, a notice has appeared in the *Times* to the effect that "the "rumours relative to an alleged looseness of "the armour plates of the iron ships had much "exaggerated" the real state of the case. This modification is made in such loose and vague terms, it by no means amounts to a contradiction of the main fact—the looseness of the armour. "So far as can be superficially seen," continues the *Times*, "the 'Warrior' maintains her "pre-eminence, in the general condition of her "hull and machinery. *Here there is no sign* of "loose plates." But what have the hull and machinery to do with the armour plates and teak backing, which are outside the hull, and may be, as no doubt they are, in the most rickety state, notwithstanding the admirable condition of the hull and machinery? The total absence of displacement or strain of any of the *internal* parts, proves the immense advantage of rigidity resulting from the cohesive strength of an iron structure, and its superiority over a wooden one, in resisting the buffeting of the waves. But the defects in the armour plating are another matter on which the *Times* retracts nothing it said the preceding day, and prudently observes, "whe- "ther any defects of this kind exist or not can "only be ascertained when the ships are placed "in dock." To these conclusions we do not demur, but, from our own sources of information, we believe the looseness of the armour plates is to the full extent as great as represented in the first report of the *Times*.

IMPROVED RAILWAY BRAKE.

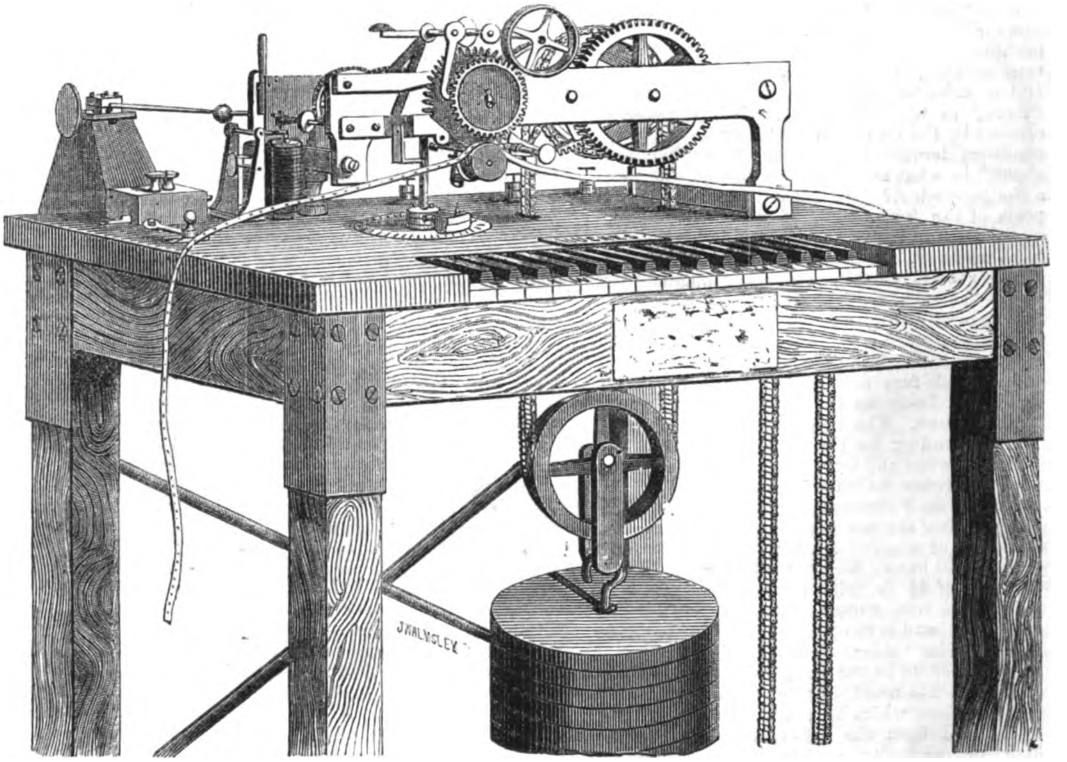
AT the meeting of the Royal Scottish Society of Arts, on Monday night, Mr. Robert Aytoun read a supplementary paper on his proposed railway brake, and the modifications suggested by the report of the committee of the Society. The brake was described in a paper read on the 8th Dec. last, and the report of the committee upon it was read and approved of at the last meeting of the society. The principal objection of the committee to the proposed brake was that the hold or grip which it took of the mid-rail was so powerful that it could tear up the road, and throw everything into confusion; but as the brake proceeded upon friction alone, just as in the case of the present system of brakes, the only difference being that he was able by means of the springs and the mid-rail to put on as much friction as might be necessary to bring up a train within a reasonable distance, while by the present system they were prevented from getting friction beyond that which was due to the weight of the tender and break-van. In the ordinary system, brakes would be applied to the wheels of the tender weighing 6 tons, and to the wheels of the brake-van weighing 4 tons, and, supposing every wheel in these two carriages acting as a sledge, the friction in that case would be 2½ tons, which would bring a train to a stand in 400 yards. In his plan he proposed, by means of springs pressing upon the mid-rail, to bring a friction of 10 tons as a drag upon the train, which would bring it to a stand in 100 yards. In deference to the opinions expressed by the committee he proposed two modifications on his plan—first, to have two spring brakes, each of half the power originally proposed for the single brake—these to be placed in the tender and van respectively; and, 2nd, to cover with iron plates the wooden mid-rail for 100 yards on either side of each station, which were the only parts of the mid-rail that would be liable to wear and tear. On the question of cost, it was objected by the committee that it would require £3,000,000 to apply this plan to the 10,000 miles of railway now open in this country; but he submitted that, while many millions had been squandered on useless railway schemes, £3,000,000 was not too great a price to pay for rendering safe 10,000 miles of railway. Mr. Aytoun concluded by saying that since the paper was written he had had the advantage of reading the evidence of Neil, the surviving engine-driver, on the Winchburgh collision. His evidence put in a striking point of view the miserable insufficiency of the present system of brakes. He saw the opposite train at a distance of three-quarters of a mile, which distance was much more than sufficient to check both trains without collision, even by the existing brakes, had there been means, as there always should be, of applying their full force instantaneously by drawing a trigger and releasing them from a catch. Not having such means at his disposal, he sounded the whistle to alarm the guards and to tell the firemen to go to the brake; he then went to the other brake of the tender himself, and put it on; he then reversed the engine; and, lastly, jumped off. The process of screwing the breaks is a tedius one, and takes up more time than they had at their disposal, which was only one minute and a-half. But suppose they managed to screw it home, and to lock the wheels, this could only have been attained after the collision was inevitable. He went on to show that there would have been no collision in this case had means existed of instantaneously applying the full force of the breaks of the tenders of the two trains at the moment when they became visible to each other, and concluded by remarking that until he read the evidence of Neil he had no idea that the collision could have been entirely prevented by so simple an expedient as he had suggested.

Mr. Sang, C.E., said that at present the only means of stopping a train was to take advantage of the friction of the wheels on the upper side of the rail, which it was well known could only be a limited source of resistance; because to bring out the full resistance to be obtained in this way it was necessary to lock every wheel of the train. Mr. Aytoun had adopted the only other expedient possible, of creating a pressure on the two sides of the rails. The proposed plan, however, would be impossible to work, because whenever there was a crossing it would be necessary to interrupt this mode of stopping a train; this rod could not be laid where two rails crossed each other. It was a serious objection, that this powerful and effective way of stopping a train was not practicable at the crossing of two lines, or at a junction, where of all places the means of stopping a train was required. This difficulty did not belong to Mr. Aytoun's plan alone, but to all plans which proposed to take advantage of side pressure.

Mr. Bouch, C.E., thought that Mr. Aytoun's plan was not so good as that which the same gentleman proposed some time ago. After some strictures on the plan, he concluded by saying that at present they are applying steam brakes to the wheels of the engine itself. This plan was coming into use on many of the English lines, and he thought it was a very effective one, and one which should be generally adopted by railway companies.

Mr. Sang remarked that there are frequent complaints on the part of the public that trains going at the rate of twenty miles an hour do not go fast enough. When a train was going at sixty miles an hour, however, it should be understood that the velocity was equal to what it would be if the train was placed on the top of the steeple of St. Andrew's Church, and the supports being knocked away, it fell to the ground. Engineers were at present devising the best means to break such a fall, by trying to discover the most powerful brake to arrest a train going at the rate of sixty miles an hour.

PROFESSOR HUGHES' TELEGRAPHIC TYPE PRINTING INSTRUMENT.



PROFESSOR HUGHES' TELEGRAPHIC TYPE PRINTING INSTRUMENT.

The apparatus for printing by the aid of electricity, which we illustrate in the annexed engraving, was invented and patented in this country by Prof. Hughes. We find that, after many futile attempts to introduce it into practical use in this kingdom, the invention was applied in America, where it achieved great success, and, after working successfully in France and Italy, the apparatus has found its way back to England. The United Kingdom Telegraph Company have adopted it, and secured the right from the inventor to grant licenses for its use in this country. There can be no question as to the efficiency of the instrument. Mr. Bright's speech at Birmingham, on the 15th of January, was transmitted by the instrument at greater speed than the reporter could supply "copy" from his notes.

The principle upon which the apparatus is based is that of a synchronous movement of clockwork trains, driven by weights, and separated long or short distances apart, moving independently of one another; the regulation is effected by vibrating rods. But as absolute synchronism is unattainable, the object of the inventor has been to introduce a correction sent by the one apparatus to the other apparatus at the distant point, the instruments thus becoming their own correctors of any fractional differences of speed, and preventing their accumulation. The electrical waves are transmitted by a revolving arm, carrying the segment of a circle as a contact-maker, and the arm revolves at the same speed in each apparatus as the type-wheel; when a key is pressed a metal plate in connection with the battery is forced upwards, and meets the contact-maker as it revolves, scrapes along its surface, the current passing the while, and is then thrown back by the contact-maker, and brought to its normal potition of rest by a constant spring. The letters are printed while the type-wheel is in revolution, and the type-wheel is driven by friction, which allows of its being moved backwards or forwards by mechanical means. Each apparatus registers the signals sent by it, and all letters are produced at the distant end by a single wave of electricity. This wave of electricity performs but one duty, that of releasing a soft iron armature retained in contact by a pair of induced electro-magnets, the wave tending to produce magnetism of an opposite polarity to that of the magnetism induced. A very slight disturbance of the attractive force of the induced magnetism is sufficient to release the armature, which is constantly pressed against by a spring; the electrical apparatus is therefore very sensitive, and being acted upon at the contact point, or most favourable position of the metals, exercises a maximum force. The armature, in springing up, releases the printing machinery, and a letter is produced. The train is stopped or set in motion in the ordinary way. When the apparatus at both ends are started, a ball revolving with the vibrating rod geared to the train, is advanced or drawn back, so as to describe a larger or smaller circle, as it is desired to drive at lesser or greater speed. Any variation in speed is detected as follows:—At one end, say Birmingham, the operator sends blanks, by touching his key corresponding to the blanks on the type-wheel, if London prints A, then B, and so on, the apparatus at London is running too fast, and he advances a ball; if he receives Z, then Y, and so on, his apparatus is running too slowly, and he draws the ball back, until his apparatus also makes but blanks, when both are ready to communicate.

Blanks may be struck at every revolution, or at every five, or ten, or more, thus testing the synchronism more severely. In the face of the instrument there are 28 keys, arranged like the keys of a piano; these 28 keys correspond with 28 metal pieces or plates, working upwards through slots formed all round a circular disc of metal, on the top of which, but not in connection with it, the arm and contact-maker revolve. The type-wheel and this arm revolve together, and when a key is depressed, a plate corresponding with the letter touched is raised; the position of this on the disc is such, that at the moment the arm and contact-maker touch the plate in their revolution, the corresponding letter on the type-wheel is over the printing roller, at Birmingham and at London; the current instantaneously passing releases the printing gear at both places, disengaging a detent, a cam driven by the clockwork train immediately presses the paper against the type wheel, and a letter is printed whilst at the same instant, by a graduated movement, the paper is carried on a space ready to receive the next impression. At the same instant that the letter is printed, a cam, also driven by the train, is forced up into deep grooves in a wheel in each apparatus, corresponding with the type-wheel in such a manner that, if either instrument tend to advance, it is checked; or if the tendency be to fall in arrear, it is forced forward. This takes place with every signal sent, so that at each signal the type-wheels are, so to say, connected with one another. It will thus be seen that at each depression of the key a wave of electricity is sent, a letter printed, and the speeds of the apparatus are corrected.

SUCCESSFUL EXPERIMENTS WITH PROJECTILES.

Late experiments with the famous Stafford projectile and sub-calibre shell, says the *Scientific American*, show that it is one of the most formidable weapons of its class. In Washington, on Monday, Jan. 26, 1863, a shell weighing 86 lbs. was fired from a 150-pounder Dahlgren rifle, with a charge of 15 lbs. of powder, at a range of about 50 yards, into a target representing a section of the "Warrior's" broadside. The shell exploded in the target, between the plating and timber braces, and blew the same to fragments. Also, a shot weighing 108 lbs. was fired at the same target, at the same range, and went completely through and buried itself five feet in the bank behind. The wood and iron of the target were driven before the shot, which made a very ragged hole, and flew in all directions. Previous experiments with these projectiles proved conclusively that targets of 9-inch iron plates, backed by 21 inches of hard wood, can be readily penetrated when fired from a Dahlgren gun. Indeed, the inventor of this shot thinks that the Dahlgren gun is one of the best in the country; a great many of his experiments have been conducted with it; and he is satisfied to endorse its virtues as a national arm. Experiments were also made at West Point with the Stafford projectile, at which the most favourable results were obtained. We have before us an official report of them, signed by Captain Benet, of the Ordnance Department, in which their good qualities are set forth. Angulated targets, nine inches in thickness, it is said, can be penetrated with ease.

The *Telegrafo* of Barcelona gives a strange account of an apparatus for flying in the air, invented by a farm labourer named Orujo, residing near Malaga. It consists of fans attached to the heels, and large wings extending from the shoulders to the waist, and moved by the hands. The inventor, the above-named journal states, had already risen to a height of 200 yards, and moved about in all directions, even against the wind. He had also performed the distance of a league in less than a quarter of an hour. This reads something like a bit of Yankee invention.

The Association of the Chambers of Commerce, which held its annual meeting at Palace-yard, Westminster, this week, considered, among other things, the patent laws and the metrical system.

HUNT AND CO.'S MACHINE FOR CUTTING BEVEL WHEELS.

F.C.I.

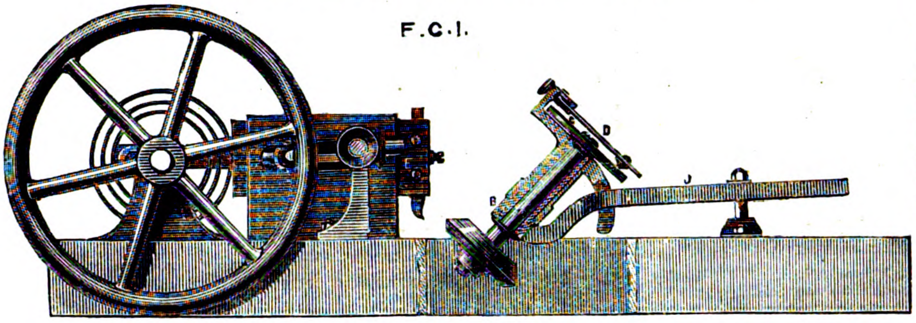


FIG. 2.

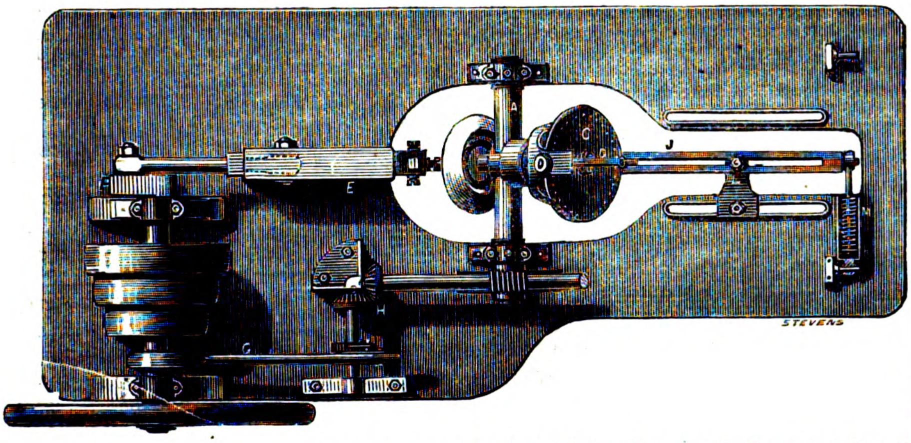

HUNT'S MACHINE FOR CUTTING BEVEL WHEELS.

In a late number we alluded at some length to machines for shaping the teeth of wheels. The following is a detailed account of the ingenious machine for cutting bevel wheels that was exhibited in the western annex of the International Exhibition, by Messrs. Hunt and Co., Bow.

Fig. 1 of the annexed engravings represent a partial side view of the apparatus; and Fig 2 a plan of the same. Upon the bed plate, and supported by means of plummer blocks, is a cross shaft A, which carries a metal piece or socket B, through which a spindle passes. To this spindle the bevel wheel to be operated on is fixed. The upper part of the spindle has also fixed to it a division plate C, on the surface of which a number of small holes are made, and into which holes a pin on the end of the spring arm D enters, to hold the wheel rigid while being cut. The tool holder E is held in a traversing carriage on the bed plate, and caused to travel to and fro by means of a crank F, driven in the manner shown in the engraving. The crank shaft is furnished with an eccentric and rod, and which actuate a paul and ratchet wheel, in connection with bevel gearing H, and worm wheel for regulating the movement of the cross shaft A during the cutting operation. When one side of a tooth of a wheel has been cut the worm wheel is thrown out of gear. The lever J is moved sideways till the tool P *a* arrives in the middle of the space between the cogs or mould to be cut, when the lever J is raised that the wheel may be clear of the tool when the division point is released, and the division plate moved to the next division, and so proceeds until one side of each cog is finished: the tool is then withdrawn, and replaced by another, with the cutting edge on the opposite or reverse side. Before commencing cutting the opposite side of the wheel, the guide cog or pin and the steel edge L, must be moved to the other side, and the spiral spring M fixed on the other bracket; the wheel is then adjusted by turning a thumbscrew; the side of the cog to be cut is brought in a line with the tool, when it is continued, as in the first instance. When this part of the operation is finished, the portion of the wheel which has been used for supporting it on the spindle arbor is cut off by means of turning. The spaces in the cogs of the bevel wheels or pinions are formed or shaped to the cycloidal curve, or varied according to the pattern which may be preferred, as regulated by the shape of the guide piece.

ON THE PURIFICATION OF COKE.

By M. E. Kopp.

Though in very many cases coal and coke are already substituted for wood and charcoal, there are, neverthelsss, certain metallurgic operations for which charcoal is still used, through fear of the impurities of the coke injuring the quality of the product. We need only cite as instances the blast furnaces, furnishing cast-iron with wood or charcoal, the fining of iron by charcoal, the preparation of what is called German shear-steel, by fining steely cast-iron, &c., with wood-charcoal. If, on the one hand, coke could be deprived of all its injurious components, such as sulphur, phosphorous, and the large proportion of earthy matters, and, on the other hand, if all the useful matters in which it is deficient could be added to it, such as carbonates, and alkaline chlorides and silicates, there can be no doubt that, thus purified and modified, it would in nearly every instance economically replace charcoal.

Innumerable methods of purifying and ameliorating coke have already been proposed; but some are almost inoperative, others too expensive, and others again would rapidly destroy the coke furnace. M. Scheerer (*Berg-w. Huttenm.*, Zeit., 1854, No. 29) passes a current of water vapour through the furnace of red-hot coke, thus reducing the proportion of sulphur from 1·1 per cent. to 0·4 per cent. M. Bleibken damps the coal previously with milk of chalk or lime (*Dingl. Journ.*, vol. cxlvii., p. 295), and so produces limed coke. MM. Claridge and Roper (*Rep. of Patent Inv.*, November, 1858, p. 375) also use water vapour, superheated (which seems useless in presence of coke, at almost white heat); others mix sea salt with the coal, or add it to the coke when incandescent in the furnace and others advise the employment of fluoride of calcium, &c.

It is now some years since, in 1856 (On the Continuous Preparation of Lighting and Heating Gas), that we proposed to purify coke by very weak hydrochloric acid, and the addition of a little carbonate of soda to the coke, purified, washed, and dried.

This weak acid is generally rejected, and turned off as waste, but it is just this waste which could be admirably utilised for the purification of coke.

The process is simple enough. After the conversion of coal into coke in the usual way, the coke is taken red-hot from the furnace. In well-constructed coke furnaces this is effected mechanically; the furnace is open at each extremity, and a very thick, shield-shaped plate of cast iron, adjusted to a strong toothed rod of iron, which is propelled with great force by gears, gradually pushes before it, and finally expels from the furnace, in a single block, the whole of the prepared coke. The incandescent coke is generally extinguished by throwing a large quantity of water over it. This water we propose to acidulate with hydrochloric acid; or, simpler and better still, to let the incandescent coke fall into a reservoir, containing the slightly acid water flowing from the second condensing tower.

The incandescent coke may contain protosulphide of iron, proceeding from the pyrites, which, at red heat, have lost half their sulphur, sulphide of calcium proceeding from the reduction of sulphate of lime, phosphates, silicates, &c. By contact with the diluted hydrochloric acid, the sulphides of iron and calcium are transformed into chlorides of iron and calcium, with disengagement of sulphurreted hydrogen, which is carried away by the water vapours, escaping abundantly when the coke is extinguished. The phosphates are converted into soluble biphosphates, and even the silicates may be attacked; the bases dissolve, as chlorides, a portion of the silica at the same time becoming soluble, which happens when a silicate is digested, hot, in a very diluted acid. Were the coke only sprinkled with hydrochloric water, and allowed to dry immediately from the heat retained in it, even when the burning had ceased, the chlorides, biphosphates, and silica would remain; but certainly the sulphuretted hydrogen, and with it nearly all the sulphur, would have been eliminated. But, on the contrary, if the coke were impregnated with acid solution, and were then washed with water, a large portion of the impurities specified would be expelled by the washing. The washed coke can then be dried, either in the air, or by the unutilised heat of the coke kilns. To impart to it still more the qualities of charcoal, it may be sprinkled with a weak solution, or powdered over with dry carbonate of soda, as free as possible from sulphate, about a few milliėmes the weight of dry coke being sufficient.

The carbonate of soda, prepared by means of kryolite (double fluoride of aluminium and sodium), naturally containing no trace of sulphate, answers best for this purpose.

In most instances finely powdered kryolite may be used with advantage, and one-third to one-half per cent. added to the coke. Kryolite supplies economically the alkali which the coke lacks; and though the soda exists in this mineral in the state of fluoride, there seems no doubt as to its beneficial influence.

We have had occasion to make several trials in fusing cast-iron and steel with coke purified by weak hydrochloric acid, with addition of a little carbonate of soda, and the results were decidedly favourable, as compared with those obtained with ordinary unprepared coke.

Finally, we think that a series of experiments should be undertaken, to ascertain what effect kryolite used in blast furnaces would have on the yield and the quality of cast-iron, and in puddling furnaces on the properties of puddled steel. Kryolite is found in very large masses in Greenland, and the price will decrease as the applications of it become more numerous.—*Repertoire de Chimie pure et Appliquee.*

IRON-CLAD SHIPS.

BY CAPTAIN C. P. COLES.

THE present transition state of navies, and the great progress which has been made in the construction of large guns, especially in America,* leave but little doubt that we are as certain to pass from 68-pounders to 300-pounders, as we were from 32-pounders to 68-pounders when iron-clad ships became a matter of necessity; these convictions have induced me to print the following tables and calculations, showing the relative cost of constructing and maintaining a fleet of iron-clad ships with broadside ports that cannot carry these guns, and shield ships that would carry them. The comparative destructive powers of these vessels must be computed from the actual weight of broadside thrown from guns protected by armour plates: and to make this comparison as clear as possible, I have separately compared the "Prince Albert" shield ship with four different classes of iron-clad vessels with broadside ports. An examination of the following table (A) will enable some conclusion to be arrived at as to the comparative cost, tonnage, and fighting powers of shield ships and ships with broadside ports.

In comparing the destructive powers of these ships's broadsides, it has to be remembered that the mere weight of metal, if taken alone, would convey but a small idea of the effect they would produce; as a few heavy projectiles from large guns might destroy a ship which would receive little or no injury from a broadside of the same weight of metal, made up of a number of shot of a smaller nature. But setting aside the great advantages of heavy shot, it is now known that shells, under favourable circumstances, can be made to penetrate iron plates 4½ in. and 5½ in. thick. These shells, to be effective, must contain large bursting charges, and be of great size and weight—two conditions which necessitate the employment of guns too heavy to be used in ships with broadside ports.

Taking the comparative costs of the vessels, stated as in table A, a reference to the accompanying table B will give a very correct idea of the great saving of expense that would have resulted from the application of the shield principle to the ships now built or building, a saving which may be stated at nearly £3,000,000, viz.:—

In construction . . .	£1,853,566
6,954 men being required, at £48 each = £333,792 per annum, representing a capital of .	£953,600
Total . .	£2,807,166

Apart from the above considerations, a matter of even greater importance is at issue. The great draught of water of these enormous and unwieldy ships with broadside ports, render it indispensable that our docks and basins should be reconstructed to receive them. They are, for the same reasons, rendered incapable of entering many of the foreign ports, or approaching, if needs be, within an effective distance of an enemy's coast; whereas with the light draught of water, and the smaller dimensions of shield ships, no such objections present themselves. For such ships, the existing docks in our Government establishments are large enough; and in time of war those of our merchant yards would be available, if required.

* The following extract is from a letter, dated New York, Jan. 20, 1863, and is of undoubted authority:—"The number of 15-in. guns already cast and mounted is 34. The foundry at Pittsburgh is turning out three a week, the foundry at Providence one a week, and the foundry at Boston two a week; making an actual production of one 15-in. gun a day. These guns fire a solid round shot of 450 pounds weight, and a shell of 370 pounds weight, containing 17 lbs. of powder. The charge of powder in the gun is from 40 lbs. to 50 lbs., and you can easily imagine the effect to be terrific. With this gun we do not aim so much at penetrating as crushing; and the idea is, that the sides of one of your iron-plated ships would be entirely broken by shots of such enormous weight, moving with an initial velocity of 1,400 ft. per second, a rate which we have reached with recent trials at the Washington Navy Yard."

ARTIFICIAL ILLUMINATION.

Dr. Frankland delivered a lecture on "Artificial Illumination," at the Royal Institution of Great Britain, on Friday evening, Feb. 13. He commenced by stating that it was ten years since he delivered a lecture on the same subject at the Royal Institution. In the interval very little improvement had taken place in the means of producing artificial light; but recently a new illuminating agent had been introduced, and the magneto-electric light had received an important application. The lecturer exhibited and described the electric light; and went on to speak of Dr. Faraday's discovery of the magneto-electric spark, and its application to lighthouse illumination. Professor Holmes' machine, he said, had been in operation at the South Foreland lighthouse for twelve months without break or failure. The electric light, however, was of no use for domestic purposes; its cost was too great, and it was only available where light of the greatest intensity was required. Some improvements, in the form of mechanical contrivances for keeping the carbon poles at proper distances, have been introduced, as instanced in the clock-work arrangement in Duboscq's lamp; and the electric light had received a modification in the substitution by Mr. Way of mercury for the carbon poles. The light emitted from the mercury poles Dr. Frankland showed to be far inferior to that emitted from the carbon points. He stated that it only amounted to one-twentieth: but the battery used was not the best adapted to procure a good light, as it required quantity rather than intensity.

In gas manufacture very little improvement had been made in these ten years. Sulphur was still found in it in considerable and, perhaps, undiminished quantity. It was present in the form of bisulphide of carbon, which was irremovable by the ordinary modes of purification. A method, however, had been devised by the Rev. — Bowditch, the Vicar of Wakefield, by which almost all could be easily got rid of. It consisted in passing the gas over hydrate of lime heated to 400 degs.; by this means the sulphur of the bisulphide of carbon was brought into the form of sulphuretted hydrogen, which was removed by the ordinary oxide of iron purifyer. On the small scale, this process was found to take away nearly all the sulphur, and it might, perhaps, answer as well on the large. The lecturer stated that he had never found more than nine or ten grains of sulphur in 100 cubic feet of gas, but he was aware that others had found as much as 40 or 50; and he believed the quantity commonly present was about 20 grains in the 100 cubic feet. Recently, a new illuminating constituent, acetylene, had been discovered in coal gas, and the discovery may, perhaps, entirely revolutionise the manufacture. At present, a comparatively low temperature is employed in the manufacture of gas; but an intense heat is favourable to the production of acetylene. It is produced when carbonic oxide and carburetted hydrogen are strongly heated together. It would be necessary, the lecturer said, to investigate how this body could be produced on a large scale to increase the illuminating power of gas; but the subject was still *in embryo*. Acetylene may be obtained from gas by passing it through a solution of subchloride of copper, by which means what might be called an acetylide of copper was produced, in the form of a brick red precipitate. The lecturer showed that this acetylide of copper was decomposed on the addition of dilute hydrochloric acid, and that the acetylene evolved burnt with a brilliant flame. The acetylide of copper is an explosive compound, which has been the cause of several accidents where gas has been passed continuously through copper tubes. It is exploded by friction, percussion, and by heat.

The use of animal and vegetable oils for illuminating purposes had received no new development the past ten years; but a new source of light of the greatest importance has been distilled by Nature herself. The native oil of the United States and Canada is obtained in immense quantities; from the latter country alone as much as 20,000,000 of gallons have been procured, which, it has been calculated, would give as much light as 180,000,000 of pounds of sperm candles. The importance of these oils could not be overrated. Some accidents had resulted from their use, apparently from careless manufacture, it being necessary to remove the lighter constituent oils before they could be used with perfect safety. The lecturer explained that it was necessary to burn these oils, as well as Young's paraffin oil, in lamps made of some badly-conducting material like glass, so that the oil in the reservoir might not become heated; and he showed the explosiveness of some oils, and non-explosiveness of others, when heated to 120 degs.

The following diagram exhibits the illuminating equivalents of various materials, showing the quantities of other substances required to give the same amount of light as would be obtained from one gallon of Young's paraffin oil:—

Young's paraffin oil	...	1·00	gallon.
American rock oil (1)	...	1·26	„
„ „ (2)	...	1·30	„
Paraffin candles ...	...	18·6	pounds.
Sperm „ ...	...	22·9	„
Wax „ ...	...	26·4	„
Stearic „ ...	...	27·6	„
Composite „ ...	...	29·5	„
Tallow „ ...	...	39·0	„

The comparative cost of light was shown in a diagram exhibiting the compatitive cost of the light of twenty sperm candles, each burning ten hours, at the rate of 120 grains per hour:—

		s.	d.
Wax ...	... ...	7	2½
Spermaceti	... ...	6	8
Tallow ...	... ...	2	8
Sperm oil	... ...	1	10
Coal gas ...	... ...	0	4½
Cannel gas	... ...	0	3
Paraffin candles ...	... ...	3	10
„ oil	... ...	0	6
Rock oil ...	... ...	0	7½

It was thus shown that paraffin and rock oils are the best sources of light for domestic purposes, inasmuch as they give the largest amount of light with the least development of heat.

Amount of carbonic acid generated, and heat evolved per hour, in obtaining a light equal to twenty sperm candles, each burning 120 grains an hour:—

		Carbonic acid in cubic feet.		Units of heat.
Tallow	...	10·1	...	100
Wax Spermaceti	...	8·3	...	82
Paraffin	...	6·7	...	66
Coal gas	...	5·0	...	47
Cannel gas	...	4·0	...	32
Parafin oil Rock „	...	3·0	...	29

The lecturer then entered upon the chemical and physical principles concerned in the production of light, explaining that it was produced by the incandescence of certain solids or vapours. The incandescence of liquids is never used, and in one case only—the mercurial light—is a vapour employed. In all other cases it is the incandescence of solid carbon. He explained, too, how the light was effected by the pressure of the atmosphere and temperature; a great pressure of the atmosphere brought more solid particles to incandescence, and a fall of one inch in the barometer involved a reduction in illuminating power of 5 per cent. When the air supplied to the burner, or the gas itself is heated, an increased illumination is obtained with the same consumption of gas, amounting to 62 per cent.; or, for an equal amount of light, the saving of gas would amount to 83 per cent.

Mr. Frankland then explained the conditions of a good light, and showed that it was necessary that light for ordinary purposes should contain all the colours of the spectrum, as the light obtained in all common modes does. He showed the effects of the monochromatic light of sodium on colours. Solar light, he stated, was defective in showing colour, as it was incapable of showing tints brought out by sodium, and that, consequently, a pigment containing these tints would be invisible by daylight. Sunlight passed through a variety of vapours, of which sodium was one, and the lecturer showed how the sodium band in the spectrum was obscured when the light passed through the incandescent vapour of sodium. Solar light, however, had one great advantage over that from all other sources, inasmuch as it was attended with less heat, and, consequently, ordinary daylight produced less discomfort in the eye than any artificial light.

The disadvantage of having heat associated with light was, that the greater part of it was absorbed by the humours of the eye, there causing pain and discomfort. The behaviour of the eye towards the heat of a moderator lamp had been examined, and the following diagram represented the amount reflected and absorbed by the various media:—

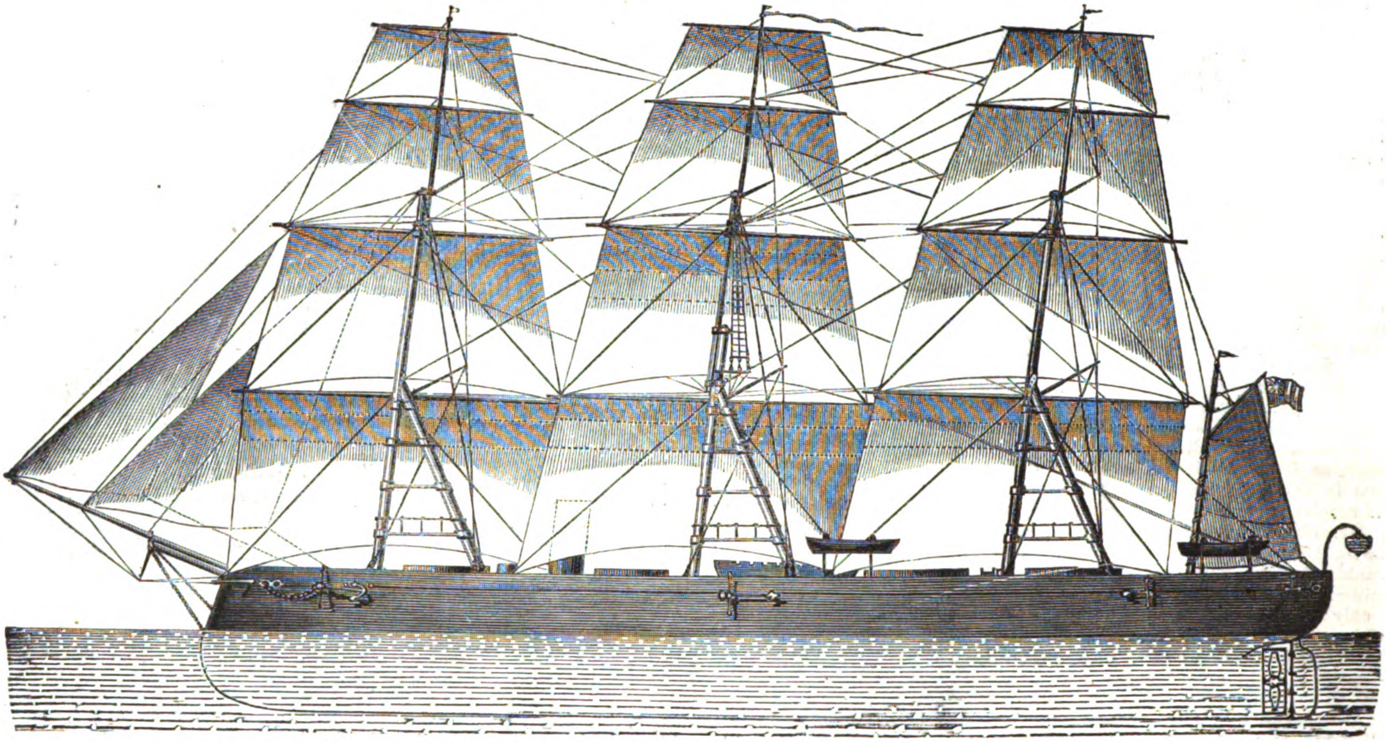
	Eye of ox.	Eye of sheep.	Eye of pig.
Rays reflected at surface of cornea	4	4	4
Rays absorbed by cornea	59·8	56·9	57·5
„ „ aqueous humour	19·2	—	20·6
„ „ crystalline lens	6·8	30·7	7·2
„ „ virtreous lens ...	2·5	—	1·6
Rays which penetrate to retina ...	7·7	8·4	9·1
	100·0	100·0	100.0

In conclusion, Dr. Frankland alluded very briefly to the difficulties in the way of applying the discoveries of science to every-day purposes. It was thirty years ago that Riechenbach first made paraffin and paraffin oil in the laboratory, and twenty years elapsed before any practical use was made of them. It was thirty years since Dr. Faraday showed the magneto-electric spark. How long shall we have to wait for any development of thermo-electricity, or the direct transformation of heat into light by electricity? In the magneto-electric machine the transformation was accomplished by the intermediate transformation of heat into mechanical force, by which there was experienced a loss of nine-tenths of the heat force. The man of science was rewarded by the truths which he discovered; it was not his function to apply these truths to useful purposes. That required quite different powers of mind.

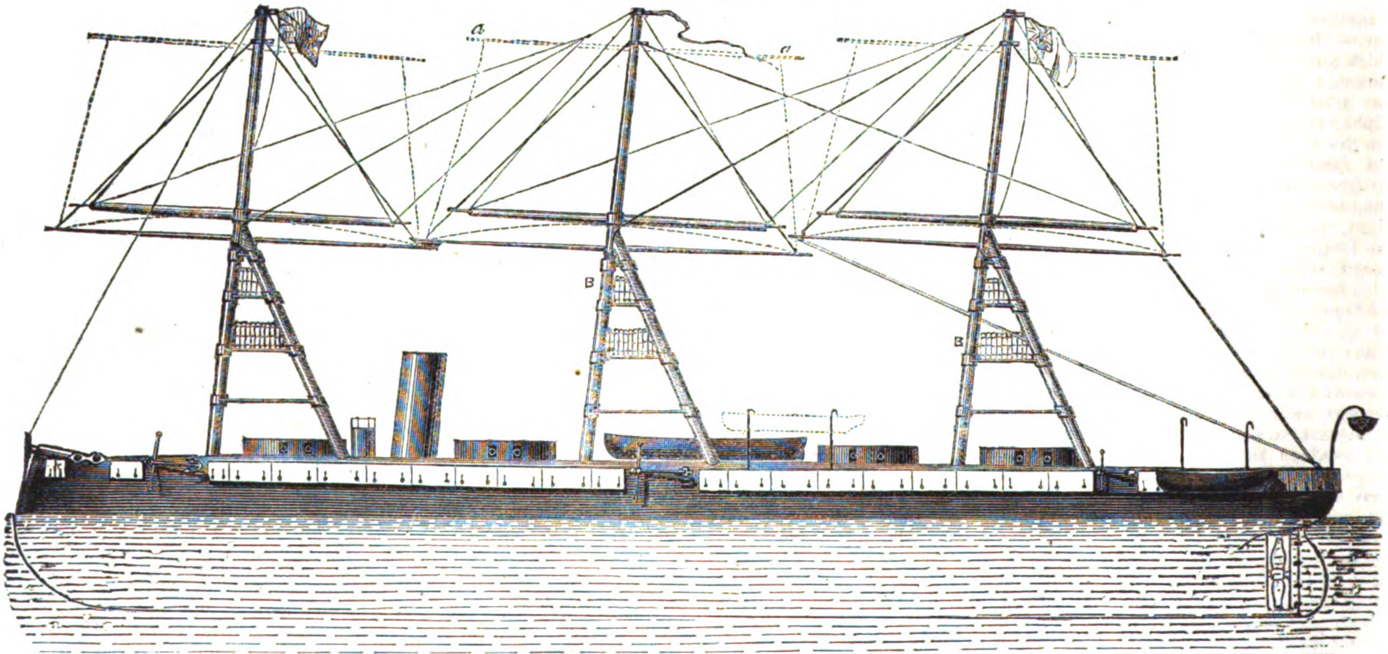
HOW TO USE CALLIPERS.

It may be safely assumed that comparatively few mechanics use callipers properly. There are many different forms of callipers with which all mechanics are familiar, such as those having springs, and those which are secured, when set, by set-screws biting on an arc. While all these have their several merits, commend us after all to the old-fashioned sort made with two legs, two washers, and a good rivet. Now, what is the reason that one man will always make a good fit when turning a shaft to fit a bore, or the reverse, while another man makes a botch of it? The reason is that the former knows how to take a size, while the latter is ignorant of that duty. Sizes when turning are generally taken either with a pair of callipers or a standard gauge. It would naturally be supposed that with the gauge, inaccuracy of measurement would be impossible. It is possible, however, and frequent, because the workman has not sufficient delicacy of touch to use the gauge properly. Callipers are very sensitive and are often used for extra nice work; if, however, the work has to be multiplied many times, then the use of callippers is not economical, and we must substitute some other method; moreover, gauges are costly tools, and but few shops are able to own complete sets; for general work, therefore, we must rely upon the callipers. Blacksmiths have tools which resemble callipers, but they are uncouth and rude. The majority of men of that calling, when using them, set their callipers somewhere near the size they want, and then upon comparing the work with them, *jab* them over the rod or shaft, as if they were going to cut it in two. The consequence is that the size of the work finished depends very greatly upon the resistance which the joint opposes to the blacksmith's strength. It is needless to remind the machinist

CAPTAIN COLES'S PATENT IRON TRIPOD MASTS.



No. 1.—Shield Ship under all plain sail, with Tripod Masts, spreading 32,456 square feet of canvas.
Note.—Main Topmast is here fidded, as may be, if preferred.



No. 2.—Shield, with a broadside of eight 300-pounders, prepared for action, with her yards braced fore and aft.

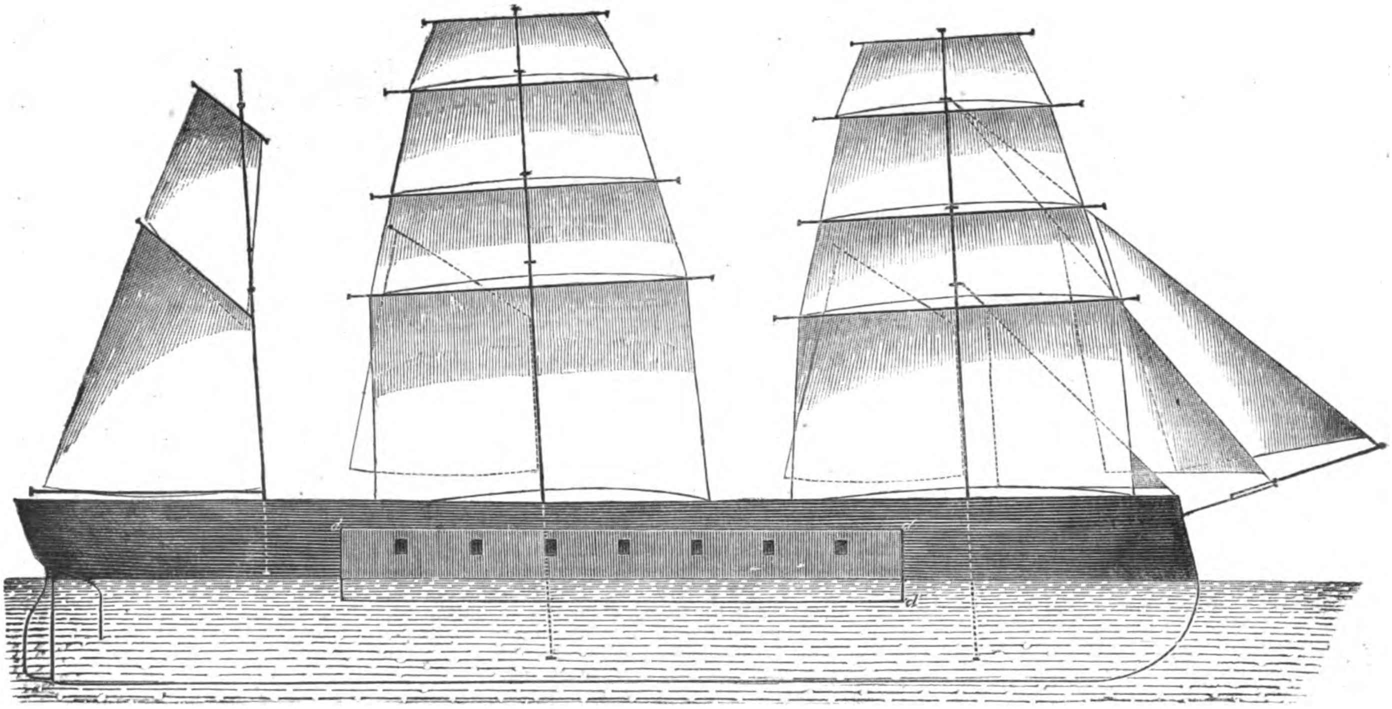
that violence or pressure, applied to tools of this kind, only distorts the measurement and results in "bad jobs." The object with some workmen seems to be to find out how much the callipers will spring in going over a shaft without altering; not to ascertain how much metal must be removed before the requisite dimensions are attained. It is safer to go by the sense of sight than it is by the sense of feeling, in all cases where it is practicable to do so. When we can see that the callipers barely touch the object measured, we know it is of the proper size, but when we only feel of it, accuracy depends almost wholly upon a delicacy of feeling which all persons do not possess. When we say accuracy, we do not mean hap-hazard accuracy, that will admit of being somewhere in the neighbourhood of the right size, but we mean absolute mechanical integrity, such as is obtained in the sewing machine and in the manufacture of our best steam-engines. Many new inventions are rendered useless and thrown aside as impracticable, solely because rudely made; let us then endeavour in the use of all tools, but more especially in the employment of those upon which the proper working of other parts depends upon good fits, to be as faithful as our abilities will allow us to be.—*Scientific American.*

CAPTAIN COLES'S PATENT IRON TRIPOD MASTS.

THE iron tripod masts, lately patented by Capt. Cowper Coles, R.N., and particularly alluded to by Lord Clarence Paget on Monday evening last, consists in constructing masts of a central and two or more side tubes of iron or steel.

The tubes pass through and are keyed to the decks, the central or main tube being carried up to form the topmast—the two side tubes being carried up to the height of the lower yard, thus forming a tripod lower mast, the topmast being secured as a Palacca mast with two very large buckstays, outriggers, and stays. The lower masts

CAPTAIN COLES'S PATENT IRON TRIPOD MASTS.



No. 3.—"Defence" under all plain sail, spreading 22,251 square feet of canvas.
N.B.—The shaded portions, *d*, *d*, *d*, *d*, are covered with armour. Broadside, seven 68-pounders.

become as it were self-supporting, and shrouds and other supporting rigging are dispensed with. If preferred, a topmast may be fidded in the ordinary manner, but the Palacca has many advantages. It has been often erroneously asserted that shield ships could never be turned into efficient sea-going vessels, from the great difficulty which would be found in masting them. Now, so far from this being the case, they can be masted with the greatest ease, and the system which Capt. Coles applies to them, and which can be used in any other description of ships with very great advantage, enables them to spread, when under all plain sail, one half more square feet of canvass in proportion to their tonnage than if rigged according to the method at present adapted for our iron-clads by the Admiralty. It may, therefore, be fairly assumed that they would have under canvas a proportionate advantage in speed. The principle itself may be shortly described as the substitution of rigid iron tubes, for the lower rigging, thus forming with the masts a tripod, but the subject will be best explained by the following diagrams. Diagram No. 1 represents a shield ship of nearly the same tonnage as the "Defence" class, viz., shield ship, 3,700 tons; "Defence," 3,720 tons. A perusal of the following table will give an idea of their general dimensions, armament, and spread of canvas.

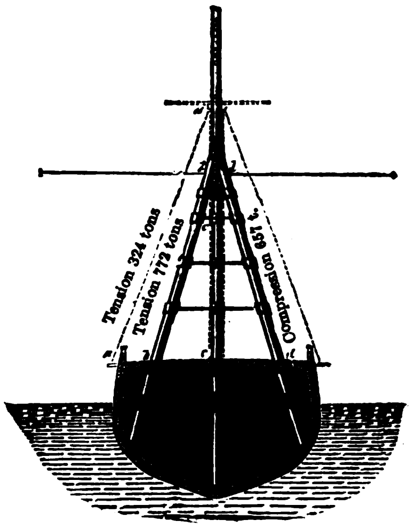
GENERAL DIMENSIONS, &c., OF "DEFENCE" CLASS AND SHIELD SHIP WITH TRIPOD MASTS.

NAME.	If partially or wholly Cased.	Thickness of Armour Plating.	Length.	Beam.	Draught of Water.	Number of Men.	Guns in one Broadside, protected by Armour.	Weight of one Broadside in lbs. thrown by Guns protected by Armour.	Tonnage.	Speed.	Spread of Canvas under all plain sails.	Weight of Masts, Sails, and Rigging.	Nominal H.P.	
								lbs.			Sq. ft.	Tons.		
Defence Class.	Partially.	4½	280	54	25·6	455	5 68ps. 2 110ps.	560	3720	11·3	22,251	163	600	It will be seen that the Tripod Masts spread 10,205 square feet more canvas with the same weight.
Shield Ship, with Tripod Masts.	Wholly.	4½	285	50	23·0	300	8 300ps.	2,400	3700	13·0	32,456	160	800	

Drawing No. 2 represents the ship prepared for action. The topgallant masts and yards having been struck and stowed, either on deck or between decks, nothing being left aloft but the iron tripod lower masts, with their long mastheads on topmasts. The lower and topsail yards are iron, fitted with Cunningham's topsails, which, when the ship is going into action, can be either rolled up or set as illustrated at *a a a a*. In the latter case, with the yards braced fore and aft, the sails would assist in keeping the ship steady, and by so doing add no little to the accuracy of the practice, and to the effect which would be produced upon the enemy, by the eight 300-pounders, with which, as will be seen, the shield ship is armed. The following advantages are contemplated from using iron tripod masts.

1. From there being no lower rigging, the great training powers of the shield are not interfered with; even with ordinary rigging the guns in shields would have greater training than when in broadside port holes.

2. From their being no lower stays, the yards can be braced nearly fore and aft, or in a line with the keel, enabling a ship so rigged to set her square sails, and when under steam steer her course, when, with the present rig, she would be obliged to keep her square sails furled; indeed, square sails fitted on these masts would stand as long, if not longer, than fore and aft sails, with the gaff bagging over to leeward. Naval men all know how much more powerful square sails are than fore and aft sails; and, in conjunction with Mr. Cunningham's self-reefing topsail, this is most important for screw ships. On steaming head to wind, the yards being braced fore and aft, and there being little rigging on top-hamper on the topmast, there would be but a small resistance to the wind.



No. 4.—*a*, *a*, represents the lower rigging by which the main of a ship would be secured by the old plan, viz., nine six-inch wire shrouds of a side, the cohesion or breaking strain of which is equal to (9 × 36) = 324 tons.

b, *b*, represents one tube or support of the tripod masts, the cohesion or breaking strain of which is equal to 772 tons. But the centre tube or mast, *c*, *c*, would also be supported by the opposite tube, *d*, *d*, for when the ship rolled one would be in tension while the other was in compression, making the comparative support of tubes and rigging as (772 + 657) = 1,429 tons to 324 tons.

3. In going into action, the topsails can be set or taken in without exposing any of the men aloft, or even on the deck, the topsail, halyards, and sheets, being led down through the cylindrical masts and worked between decks.

4. When these masts are shot away in action, from there being no lower rigging, they would, being of iron, sink at once, as would the yards from the same cause. This, with the absence of lower rigging would greatly lessen the chance of the screw being fouled, one of the greatest dangers to which our ships are now exposed.

5. The masts will be much stronger and more durable than wooden ones, secured according to the present mode by numerous shrouds. Their relative strength would be as shown in diagram No. 4; and it is supposed they would possess the further advantage of being fireproof. If one of these legs were badly wounded, or shot away, the other two would mutually support each other; but how different with a single mast, which, when badly wounded, or shot away, the rigging, instead of supporting it, tends to pull it down.

6. From their being hollow they would afford additional means of ventilation in all weathers.

7. From their great strength, ships blockading or on other service, in heavy weather, would be better enabled to keep the sea and maintain their stations.

8. They afford great powers of defence against boarders by means of the mast platforms for small arm men, who would be protected by wet hammocks, *b b b b*. With the fire from these and from the turrets, which are not only shields for their guns, but rifle towers, there need be little fear of boarders making any lodgment on the decks for the purpose of attempting the much talked of "wedging the shield."

9. These masts will better withstand the shock received by the ship when giving another the stern, or when striking the shore.

10. They will, as already stated, give a greater spread of canvas with less weight than the ordinary masts with rigging, as will be seen ("Defence") with Admiralty rig, diagram 3, and shield ship with tripod rig, No. 1. Further, all the sails and yards being of the same size, the spare ones will answer for either mast.

11. The sails are so balanced as to enable the ship to stern and work well; the points of difficulty in the present rig, which are frequently the cause of serious complaints.

12. The distance between each mast in the proposed rig being governed by the yards not locking when braced up on different tacks, instead of the mizen and main masts being placed close together, whilst a great distance is left between the main and foremast, as in the "Defence" (see diagram No. 3.) Captain Coles is enabled to place the centre of effort well before the centre of flotation, so that the ship will work well, particularly in wearing, which is very far from being the case with the iron-cased ships, rigged in the usual unhandy manner. The great cause of the defective working powers of these ships is chiefly attributable to their mainmasts being placed too far aft; another is to be found in their not being able to set a sufficient quantity of canvas in proportion to their tonnage. This latter is a very grave defect, for it renders an iron-cased ship incapable, in many cases, of keeping its position in a fleet when under sail, and at a time when it may perhaps be of great importance that as little fuel should be burnt as possible. We have an expensive instance of this defect in the "Defence" during the Baltic cruise. This plan has another advantage; none of the yards are more than 91 ft. long. We lately heard of the "Warrior's" mainyard being carried away. There are a number of gigantic yards in use at the present day—yards some 105 feet long—which are frequently carried away, and that not from any want of skill or seamanship, but simply from the weakness consequent on their great length.

13. The topsail yards can be lowered down on the lower yards in action, and the two lashed together, so that if one is shot away it will be kept aloft by the other.

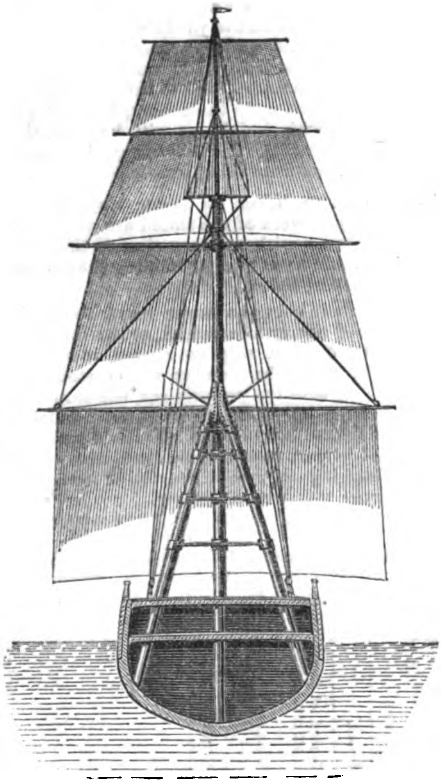
14. The last, though not the least, advantage to be derived from the adoption of these tripod masts would be the great saving which would be effected in the expense annually incurred through the enormous deterioration in the rigging of those men-of-war which it is thought necessary, according to the present system, to keep ready for service in the steam reserve. Ships with the tripod mast would always be comparatively ready for sea, and whilst their perishable sails and running rigging remained stowed away below, nothing would be exposed to the mercy of the elements their iron masts and yards, as shown in diagram No. 2. Important as this tripod rig may appear for men-of-war, we believe it will be found useful for our mercantile marine, when advantages will arise from the saving of wear and tear of rigging and of loss of life and property.

Diagram No. 4 will give its relative strength. The tripod mast is secured as when heaving a ship down, viz., by shears, and seamen well know the enormous strain that a mast so secured will bear. It has to be remembered that with rope shrouds a mast is only sustained on one side, unless the vessel is dead before the wind; but the tripod masts will receive support on all sides; for whilst one portion of the structure is in tension the others would be in compression, so that each portion of the structure would be doing its work towards resisting the strain that may be brought against it, whether from pitching, rolling, or any other cause. From this great strength we conclude it will be impossible for a ship to loose her lower masts from the elements.

It is well known, that being dismasted is one of the most frequent causes of ships being lost or deserted, and that the annual loss of life and property is something fearful to contemplate; and even when a dismasted ship is picked up or saved by another, having been reduced to this helpless condition, her cargo is frequently ruined from the water which has poured into her whilst lying unmanageable in the trough of the sea.

It has also to be considered that our clipper ships, after a run to China, often require a thorough outfit, if not an entire new set of lower rigging.

Change of climate and temperature often endangers the masts of ships, from the effect produced upon the rigging, whilst change of climate would have little or no effect upon these iron tubular tripod masts; and we think we may reasonably expect they would last as long as any first class iron built ship that they may be placed in.



No. 5.—Elevation of Mainmast, taken from astern.

It may be said that it is necessary for a mast to have some play, and these tripod lower masts would be too rigid; that argument might have held good with old wooden masts, but it is well known now that if an iron mast has play the rivets would work loose, and eventually destroy the mast, so that the more rigid an iron mast can be made the more secure and durable it will be.

INSTITUTION OF CIVIL ENGINEERS.

AT the meeting of the Institute of Civil Engineers, on February 24, John Hawkshaw, Esq., president, in the chair, the first paper read was on "American Timber Bridges," by Mr. J. R. Mosse, M. Inst. C.E.

It was stated that the early common road bridges, for spans of 100 ft. and upwards, were generally built on the lattice plan. The sides, and the top and bottom chords, were formed of planks, usually 12 in. wide by 3 in. thick, fastened together by oak trenails, 2 in. in diameter. For road traffic, with moderate spans, this kind of bridge answered tolerably well; and several of the early railway bridges were constructed in a similar way. But this structure, having been found insufficient for heavy trains, had, long since, been abandoned; though it was sometimes, but erroneously, thought in England to be the general style of American bridges.

The next design noticed was the Howe bridge, a detailed description being given of one on this principle on the Danville Railway, over the James River, at Richmond, Virginia. This bridge consisted of 11 openings, each [illegible] ft. span, the total length being about [illegible] ft., with a width of 18 ft. For each span there were two trusses, the greatest depth of which was [illegible] ft. Each truss was divided into several panels, 11 ft. wide, and the bottom chords were so arranged, that there should be only one joint in the chord pieces in each panel. The sectional area of the upper chords was [illegible] square inches, and of the bottom chords 528 square inches; the greater area of the latter being on account of the numerous joints. There were four main braces at the ends of each truss, and by means of three vertical iron tie-rods in each panel, any required camber could be easily given. Counter-braces were also introduced, by which, when keyed up, the bridge could be so stiffened, that a passing load was said to produce no additional strain. These bridges were always built of the best white pine; and the ordinary price for a single line, including erection, was from £4 to £5 per lineal foot. The usual quantity of timber employed was about 30 cubic feet per lineal foot, and the weight, including iron work, a little more than half a ton per lineal foot. Assuming a load of 3,000 lbs., including its own weight, to be uniformly distributed over the bridge alluded to, the strains would be, by the ordinary calculation,—

	Per sq. in.
On the upper chords, compression,	729 lbs.
,, bottom chords, tension,	547 ,,
,, end braces, compression,	735 ,,
,, end tie-rods, tension,	15,125 ,,

The ordinary dimensions of a bridge on this principle having a span of 150 ft., as built on the Portland Railway, were then given; from which it appeared that, the lower chord pieces of the two trusses had together a sectional area of 676 square in., and of the upper chord pieces of 520 square in. Assuming the same weight of 3,000 lbs. per lineal foot, to be equally distributed over this structure, the strains would be:—

	Per sq. in.
On the upper chords, compression,	901 lbs.
,, bottom chords, tension,	694 ,,
,, end main braces, compression	750 ,,
,, end tie-rods, tension,	18,750 ,,

These strains were greater than in the first example, and the compression of 901 lbs. per square inch on the upper chords was the limit of safety; but it was not probable that the bridge would ever be loaded to the amount assumed.
